Science and Administration

IN several recent pronouncements relating to widely different fields which touch administration the importance of the acquisition of scientific knowledge and of the adoption of scientific methods have been strongly emphasised

On Nov 30, in the course of the Sidgwick Memorial Lecture on "Democracy", delivered by him at Cambridge, General Smuts directed attention to the fact that science is necessary to the modern State and should have its functional relation to the State, he stressed the point that to-day not only is a scientific spirit needed in human affairs, but also that above all it is this spirit which is called for in the administration of human affairs A few days previously, dealing with matters relating to a narrower field, the Secretary of State for the Colonies sounded a similar note when paying a tribute to the value of anthropology in the administration of the affairs of a backward people, he urged the importance of the acquisition of a knowledge of this branch of science by young men proceeding to British Dependencies to take part in administrative work

Again, there has just been published the valuable Interim Report of the Committee on Education for Salesmanship (H M S O, price 4*d*) Salesmanship is, as this Committee understands the term, "a prime function of direction and supreme management" and "embraces the study of the fundamental principles of commerce and the planning of policy based upon them" Consequently, the matters discussed in this Report cover an important area of the administrative field in commerce, where weakness has been shown to exist in this field it has been traced to "a detached and insular attitude

and unscientific practice" on the part of our business community Not only does this Committee recommend that a "scientific study" should be undertaken of our commercial problems, but it also states that "the evidence of the Associated Chambers of Commerce emphasises the absolute necessity of expert knowledge by the salesman of goods of a technical description"

However, it is apparent that the views of the Associated Chambers of Commerce are not universally accepted in commercial circles, and that old time prejudices are still alive therein In some quarters, the view continues to be held that "too much knowledge may be a dangerous thing", the expert has not yet come into favour there Indeed, in such quarters, it is feared that in the field of salesmanship the technical dissertations of the expert may prove wearisome to the customer, and hence do more harm than good It is perhaps for this reason that another way of meeting the situation has been suggested It has been proposed to the Committee that where a machine, appliance, or article requiring specialist knowledge is being sold, the maker should attach his own expert to the staff of the agent, "so that the technical advice and service may be available on the spot" that is to say, it is seriously recommended that our manufacturers should employ two men to sell their products, where the shrewdest and most resolute of their foreign competitors employ but one, and that a highly qualified expert

In view of the foregoing proposal, it cannot be a matter for surprise that, in the course of the remarks which he recently addressed to business men at a meeting held in London, the president of the Canadian National Railways should have felt himself compelled to point out that if Great Britain is to recover its industrial pre eminence there must be an entire 'scrapping' of present day commercial policies, methods, machinery, and appliances with the object of reducing the costs of production—he might very appropriately have added and *above all of reducing the costs of distribution*

It is a general question which the foregoing pronouncements raise directly, namely, that relating to efficiency in administration and the best form of staff organisation by which it can be attained under modern conditions, whether in the public services, industry, or commerce Indirectly, these pronouncements point to the necessity for a thorough investigation into matters affecting the functions which should be assigned to the man of science and the technical expert, so that the boundaries of their spheres of responsibility may be readjusted with the view of meeting the new conditions which have arisen in all branches of human activity owing to the applications of science on every battle front

A study of administrative and management methods is a matter of supreme importance at the moment, because they are vital factors in the progress and welfare of our public services, which are increasing in many directions It must be remembered that for many decades now a gradual change has been taking place in the character of the ownership of our industrial and commercial undertakings With the growth in their size and the extension of their activities in relation both to the kind of business for which they are responsible and also the considerable area of the territory in which they often operate, individual and partnership ownership has been giving place to collective and corporate ownership Where undertakings and enterprises have been incorporated under the provisions of statutes they have, for practical purposes, lost the status of a private business, in the strict sense of the term, and have instead thereof become in effect public services Questions, therefore, affecting the methods of administration and the type of organisation adopted in them can no longer be considered to be merely matters of their own domestic concern questions in relation to their control and management possess for the public an importance to day which is only very slightly less than do questions connected with the similar aspects of administration bearing upon governmental and municipal activities and enterprises In this connexion it is interesting to note that very careful consideration has been given in Germany to the problems of management and organisation in the case of the State owned concerns which have been set up in that country since the termination of the War The significant fact stands out that the directors who have been appointed by the German Government to control and manage these concerns are men who have been selected for these positions from among those possessing *expert and specialised knowledge*, and have full executive authority within the limits of the general policy laid down The practice referred to provides a useful lesson and might with profit be imitated in Great Britain

There are signs that there is an awakening in Great Britain, and there exists a readiness on the part of progressively minded men to overhaul our old fashioned and out of-date methods and practices, In order to stimulate this feeling into action, it seems to be alone necessary for some authori-

tative body to set the ball rolling by indicating the nature of the reforms which will best suit the new conditions which have come into existence with the invasion of science into every domain of human affairs

The question which perhaps most immediately requires close and attentive examination is that connected with the proper constitution of the controlling bodies responsible for the management of government departments and of industrial and commercial undertakings and enterprises These bodies are sometimes appropriately referred to as the 'directive organ', and, as is well known, it is in them that reside the power and authority for deciding not only what shall be the character of the administrative methods and practices to be employed in the organisations for which they are responsible, but they have also the final word on questions of even greater importance, affecting, as they do, the whole well being and success in every sphere in which combinations of knowledge and effort are required, namely, on questions relating to the recruitment of the staff On these rests the ultimate responsibility for determining what type of men shall be selected for particular positions, technical as well as administrative, and also what shall be the character of the qualifications which shall be sought for in the various classes of officials

Non technical administrators and directors cannot, obviously, be so well equipped for dealing with problems of the kinds referred to above as those who have been 'through the mill', and, owing to their scientific and technical training and practical experience, have therefore acquired an intimate personal knowledge of all the essential factors which are severally involved in the solution of particular problems coming under their jurisdiction, and, what is equally important, as to the nature of the qualifications required in those to whom should be entrusted the duty of providing the most satisfactory solution of any particular problem Hitherto, a disinclination has existed in Great Britain to give men with scientific and technical qualifications—and also possessing other essential qualifications—seats on boards of directors, or to appoint them to the more important administrative positions

The crippling influence of the harmful traditions and prejudices associated with a narrow policy of the kind here indicated requires to be got rid of, only if a change of spirit can be brought about in this matter is there any likelihood of effecting a real improvement in matters of the deepest concern to the nation Desirable economies and other beneficial results would follow suitable reforms carried out in the administrative sphere, they can alone be secured by widening the scope of responsibility of the man of science and the technologists It is essential that in the case of every 'directive organ' a due proportion of those forming it shall be men possessing scientific knowledge and technical experience, and further, that men with the qualifications here indicated shall be chosen more frequently than in the past for responsible administrative posts

It has been suggested that the failure in the past to employ, to a sufficient extent, men of science and technologists in the directive and administrative spheres may have been due to the reluctance that these types of men have shown to undertake work in those spheres, or possibly to the absence of aggressiveness on their part in seeking for positions therein If this has been the case, it is imperative in the national interest that such reluctance or passivity should be overcome by them they should pay heed to the exhortation of Sir William Bragg, who, on the occasion of the opening of the new science building of St Edward's School, Oxford (on Dec 8), made a pointed reference to the needs of the day in the following terms "There is a certain type of man who is badly wanted in this country at this moment It is the scientific man who is also an administrator We need men to day who are not merely scientists, but who are also willing to take responsibility, to mix in the affairs of men, and to know something of the world"

There is another and an exceedingly important reason why men of science and technologists should play a larger and more important part than in the past in the directive and administrative spheres of responsibility It is recognised by many who have studied the problem that one of the most pressing requirements of the day is that of narrowing the zone of separation between the workmen on one hand and those responsible for the directive and administrative aspects of the work on the other Attempts have been made to secure this end In the governmental sphere officers of the administrative branch have in some cases established direct contact with the workers, and in some industrial enterprises committees of directors have been appointed to preside over departmental operations

However, there is evidence that the results in such cases have not been altogether happy Non technical administrative officers cannot hope to, and, as a rule, do not, hold their own in arguments

exchanged with workers in a technical field, and in these discussions there is often an unwillingness on their part to admit the errors in their views, and this necessarily still further strains the relations between these two groups instead of improving them, the workers naturally derive small comfort when, having got the best of an argument, they are told 'But there is no logic in administration' Similarly, interference with details of departmental operations by directors, particularly on the part of those who have no technical knowledge, can but be, and, indeed, has proved to be, harmful, it leads in the long run to inefficiency and loss In situations of the kind referred to, experienced technical men would carefully avoid saying or doing anything mischievous

Obviously, it is practically impossible to secure a proper bond of sympathy between the two groups, the directive and the workers, under modern conditions, where the control and management are vested entirely in the hands of non-technical men who are either ignorant of technical considerations or act without regard to them On the other hand, there is every reason for supposing that the risks of misunderstandings between the several groups in an organisation would be reduced to vanishing point were technical experts who have prepared themselves for the rôle called upon to play a more prominent part than hitherto in the directive and administrative spheres It is the development of a policy to secure these ends that will provide what is so essential to day a strong and effective link between science and administration

History of Science

A History of Science and its Relations with Philosophy and Religion By William Cecil Dampier Dampier-Whetham Pp xxi + 514 (Cambridge At the University Press, 1929) 18s net

MR DAMPIER-WHETHAM, in writing a general history of science, has undertaken what is, strictly, an impossible task It is therefore very easy for any critic who cares to spend a day or two in a library to that end to pick holes in matters of detail Taking the book as a whole, as in the first instance it should be, it is a fine and bold piece of work The narrative is always clear and concise and the sequence orderly, it never degenerates into the dismal catalogue of names and dates which sometimes masquerades as the history of science The mutual relations between scientific discovery and other phases of contemporary thought are generally well brought out, particularly the relations between science and philosophy

For the early history of science Mr Dampier-Whetham is in a more favourable position than his predecessor Whewell, thanks to the recent labours of scholars who have worked out special developments in special periods But for the later history the task is much harder than in Whewell's time, when physics seemed to be advancing quietly and steadily on proved foundations and biology scarcely existed Up to the end of the nineteenth century, discoveries and developments of thought can still be seen in perspective in relation to what came before and has come after, the wood can be distinguished from the trees It is when the present century comes under review that the historian's task becomes really alarming because of the abundance and confusion of material Yet the historian cannot stop earlier than the present day without cheating the reader of the most interesting part of the story It is significant that 105 pages suffice for all the time before the fifteenth century, from the fifteenth to the end of the eighteenth, 111 pages, 130 pages for nineteenth century, while 150 are devoted to the present century This division not unfairly represents the rate of advance

Modern developments in physics are well and simply described The story is of course the most exciting episode in the whole history of science It seems at the moment as though the three main lines of modern research, field physics, atomic structure, and cosmogony, are all tending towards a final synthesis which will lay bare the ultimate nature of the physical universe We can all hear the mathematical hounds in full cry, and even as we run panting far in the rear, can share in the excitement of the chase But with all the excitement it is hard to suppress a haunting fear that the end of this hunt may be like that of the 'Hunting of the Snark' However this may be, the history of modern physics can be made intelligible, the task needs knowledge and skill but is not impossible, for certain main lines of advance are clearly marked out It is when the other sciences come to be considered that the historian's task becomes really impossible There is at present abundant activity in detail, but there are no clear lines of advance, so that we can only guess which discoveries are the important and fruitful ones and which are destined to be sterile, though at the moment they may loom large The writer is bound to be guided by his interests and prejudices, and the reader in his turn will approve or disapprove according to

whether his own interests and prejudices coincide or not. A few examples will illustrate the difficulties.

The author does not mention chemistry, apart from its biological applications, in his review of the present century. This omission will undoubtedly offend the chemists, but I believe it to be reasonable. Twentieth century chemistry has been concerned with the use of nineteenth century methods for the application and development of nineteenth century theory. New methods and new theories have been left in the hands of the physicists. On the other hand, I should be inclined to dispute the prominent place given in the section on physiology to the recent work on hormones and vitamins. It is true the results are striking and have caught the public eye; nevertheless, there is reason to think that the ideas involved are too crude to have a permanent place in scientific thought and that existing methods of investigation are also very crude relative to the problems. It is pioneer and not classical work. Future generations will probably extend to present-day notions the same pitying tolerance we extend to the notions of 'caloric' and 'phlogiston'. In contrast with this work, I believe the work of Sherrington and his school, which is no more than mentioned, to be classical. Sherrington's methods are completely adequate for his purpose, and his ideas, though clothed in difficult language, are both simple and subtle. These ideas now dominate the physiology of the central nervous system and are likely to do so for a long time to come; the subject, moreover, is the central or key subject of the whole of physiology. This, of course, is a personal opinion; it is introduced merely to emphasise the extreme difficulty of dealing historically with modern work. Not only is an incredible diligence in accumulating detailed knowledge needed, but also superhuman powers of criticism and prophecy. In parenthesis, it seems necessary to protest against the omission of Sorensen's name from the paragraphs on colloid chemistry and ionic equilibria.

The author is to be congratulated on including a survey of those subjects, embryonic perhaps but still sciences, that lie on the borders of the physical sciences, such as psychology and anthropology. His choice of subjects and the views he expresses on certain controversial topics will be objected to by many, but in these regions controversy cannot be avoided except by silence.

There is one aspect of the history of science which is strangely neglected in this book as in others, but which is not without interest; that is, the effect of practical human needs on the course of scientific discovery. A few examples will make my meaning clear: first a minor one and then two more speculative but more important cases. It is a commonplace that the progress of physics depends upon the design and use of instruments of precision. But apparently no physicist realised either the possibility or the value of galvanometers for measuring small currents until Kelvin devised his mirror galvanometer in response to a purely practical demand, namely, for use with the trans-Atlantic cable when existing telegraphic methods had failed. Once the instrument was made, it was quickly applied to laboratory purposes, and innumerable discoveries have been made with it and its successors. Of course, the development would ultimately have taken place, as would the theory of gravitation without Newton, but it would have been delayed. Given an instrument or method, scientific men are quick to apply it to existing problems, but the existence of a problem does not always call forth a method for solving it; the method may come from some quite unexpected quarter.

The second example is the peculiar position that medicine occupied in the early stages of scientific discovery. As Mr. Dampier Whetham points out, the enormous success of geometry, which seemed to provide a means for obtaining genuine knowledge about the external world by *a priori* methods, blinded the Greeks (and many others until recent times) to the necessity of observation and experiment. Even apart from this, it seems that human beings are naturally reluctant to start the labour of accurate and disinterested observation. Once a start has been made, the work may be found interesting for its own sake, but some powerful ulterior motive is generally needed at the beginning. In the ancient world the desire to cure disease, in spite of the hocus pocus that always surrounds the practice of medicine, seemed to provide one of the few motives for precise observation. The best of the Greek medical workers realised that for their purpose *a priori* reasoning led nowhere and only the slow method of observation was any use. In this way were laid the foundations not only of human anatomy and physiology, but also of zoology and botany (it must be remembered that Aristotle was the son of a physician before he was a pupil of Plato), and in later times of chemistry. It is remarkable that while medicine and the studies underlying it were well launched on their scientific career, agriculture still remained for centuries dependent on tradition and superstition, as though hunger was a less powerful motive for research

than compassion Perhaps it is nearer the truth to say that the stomachs of the intelligentsia have usually been sufficiently well filled to turn their thoughts away from such gross considerations as food supply But they could not shut their eyes to disease and death, which might come to anyone at any time

Lastly, consider the case of astronomical observation The astronomical observations of the Babylonians and Egyptians were dictated by practical considerations, for determining the seasons and for astrological prediction Astrology was still a leading motive for astronomical observation almost until modern times The Greeks, who were free from the superstitious motive, seem to have done little in the way of observation Their contributions were of unique value but were theoretical — the application of mathematics to astronomy and the rudiments of a ' mécanique céleste ' But from the fifteenth century onwards there was a new stimulus to observation with more exacting requirements this again was a practical need—the art of navigation For casting a horoscope it was useful to have numerous observations, but they did not need to be precise, the seaman was not so easily satisfied What is most characteristic of modern physics is the design and use of instruments of precision and exact numerical calculation for purposes of prediction These characteristics first appeared in connexion with the compilation of the "Nautical Almanac" and map making Greenwich Observatory was founded for this purpose More than two centuries earlier, before western Europe had made any contributions to science, Prince Henry the Navigator had founded at Sagres the very first school of technology

There is another aspect of the voyages of discovery of the fifteenth and sixteenth centuries, a result this time that seems to deserve more notice than it usually gets from the historian of science Mr Dampier Whetham emphasises the fact that at this period the early men of science had to rid themselves of the incubus of the medieval outlook, an incubus from which the Greeks were mercifully free He does not, however, mention what was possibly the greatest single factor in the process of liberation, the discovery of the New World and the circumnavigation of the globe These facts proved, in a way which the most thick-headed were compelled to understand, that the traditional cosmology was not infallible, that ancient authorities could be wrong, and that even the thunders of the Vatican could not put Humpty Dumpty together again

A D RITCHIE

Man's Ancestry

Man's Place among the Mammals By Prof Frederic Wood Jones Pp xi + 372 + 12 plates (London Edward Arnold and Co, 1929) 21s net

EARLY in 1918, Prof F Wood Jones gave a popular lecture in King's College, London, on man's origin This lecture, when published by the Society for Promoting Christian Knowledge under the title "The Problem of Man's Ancestry", met with a mixed reception Anatomists treated it with neglect or contempt, those of an anti Darwinian bias hailed it with delight As the little book of 1918 is really the parent of the large work which has just appeared under the title "Man's Place among the Mammals", it is worth while to seek for an explanation of the diversity of feeling evoked by the original publication The antagonistic attitude of most anatomists is understandable They were told that man, far from being as they thought the most changed, the most specialised, the most highly evolved of all primate animals was, when his structural characters were rightly analysed, essentially a very ancient and primitive type They learned that they had laboured in vain, because in construing the evidence relating to man's origin they had been dominated by a heresy for which Darwin, Huxley, and Haeckel were conjointly responsible, namely, that there had been an anthropoidal stage in man's evolution Prof Wood Jones summarily dismissed the anthropoids living and extinct, at no time had they any lot or part in man's ancestry

The opposition offered to this thesis by anatomists can be understood, but the welcome extended to it by those of a ' fundamentalist ' turn of mind is less easily accounted for Prof Wood Jones is a convinced evolutionist, man, he declares, has been evolved, but not from an anthropoidal form He contends now, as he did in 1918, that man's independent origin has to be sought for among the small Tarsioids which appeared during the Eocene period of the earth's history It may seem to the ordinary reader that it matters little whether we include or exclude anthropoids from man's ancestry, but at the conclusion of his original lecture Prof Wood Jones made clear to his audience that a deep ethical significance was involved He said

"Were man to regard himself as being an extremely ancient type, distinguished now, and differentiated in the past, purely by the qualities of his mind, and were he to regard existing Primates as misguided and degenerated failures of this ancient stock, I

think it would be something gained for the ethical outlook of humanity—and it would be a belief consistent with present knowledge"

Herein I think Prof Wood Jones reflects unfairly on anthropoid apes Prof Elliot Smith is convinced of man's anthropoid ancestry, and yet he finds that natural man is peace loving and virtuous

The lecture of 1918 was prepared and delivered in a war atmosphere No doubt the author suffered unfairly from the fact that he was unable in the course of a brief hour to deal fully with the proofs which his critics expected him to produce He has now had ample opportunities of meeting the demands of his critics In a series of forty brief chapters, brilliantly written, illustrated by his own excellent drawings and illuminated by happy touches which reveal the author as naturalist as well as anatomist, he expounds his conception not only of man's place among mammals, but also the places which should be given to Lemurs, the Tarsiers, monkeys of the New World, monkeys of the Old World, and to anthropoid apes, both great and small It is not until we reach the thirty eighth chapter that we find what we have been waiting for—the author's conception of the evolutionary changes which converted a primitive small brained Tarsioid into a human being We particularly want to know how and when man's body underwent the structural revolution which fits it for an orthograde posture and for bipedal progression

It is just when he approaches these problems that our author, usually so precise and definite, becomes tantalisingly elusive and non committal We are told that the "proto human" stock was the first to break away from that line of Tarsioids which ultimately became separated into anthropoids and Old World monkeys Man's ancestry broke away while the basal phylum still retained all its 'primitive' features and was adapted in body and limb for life in the trees Having broken away, the proto humanoids took to walking on their hind limbs, and their bodies and feet underwent the structural revolution which fitted them for an upright posture and for bipedal progression Then the brain began to grow

"Everything would point to the fact that enlargement of the brain came in the proto human or progressive stock at a time when that stock was in possession of a very primitive type of cranium, and that enlargement of the brain case occurred at a stage in which no other evolutionary trends, save those of mere enlargement, had been initiated" (p 341)

It would be fair to presume from this statement that Prof Wood Jones attributes man's big brain to the fact that it began to grow when his skull was in a still plastic state A paragraph on another page, however (p 340), makes us hesitate in drawing this inference, for there we are informed that "Man enlarged his primitive chondrocranium by his early phylogenetic development of a large brain", here the large chondrocranium is attributed to the large brain Clearly, the explanation given by Prof Wood Jones of man's structural adaptation to bipedal progression and of his large brain cannot be regarded as satisfactory No evidence in support of such speculations is afforded by any fossil discovery made hitherto, still, as Prof Wood Jones rightly maintains, the geological records of man's evolution are still very imperfect

Having thus postulated an independent origin for man, Prof Wood Jones has to face a multitude of very difficult problems How are the long list of intimate structural resemblances which bind man to anthropoid apes to be explained? He admits these resemblances It must be realised at the outset", he writes, "that of all animals the giant apes show the nearest structural affinities with man This fact has always been realised, and it remains an uncontrovertible truth" He regards these resemblances not as an inheritance which man and anthropoid have derived from a common ancestor, but as independent acquisitions Now, in the order of Primates we do meet with surprising and definite examples of parallel or convergent evolution Nevertheless, Prof Wood Jones under estimates and under states the many and intimate structural and biological resemblances which link man to the great anthropoids He has to presume that man and anthropoids came independently by the same form of uterus, the same elaborate process of placentation, the same tendency to prolong the fœtal and infantile periods of growth and development He attempts to minimise the resemblance of the anthropoid brain to the human brain, if we did not know of the stage of evolution represented by the anthropoid brain, we should have to presume its existence, without such a presumption, it would be impossible to explain how the small and simple brain of a Tarsioid could become transformed into the elaborate brain of man

Every bone and muscle of man's body have undergone profound structural alterations to fit him to his orthograde posture The same bones and muscles have undergone similar changes in anthropoids, but to a less degree If we suppose that adaptation to an orthograde posture is a common inheritance, then we get light on how man came by his postural adaptation, for in their bodies anthropoid apes preserve stages which lead towards

the specialisations found in the human body Our author rejects such an interpretation, he supposes that man and anthropoids have independently acquired their orthograde posture, and in the process of evolution come by the same structural modifications He regards all such postural modifications as 'adaptations', and therefore useless as indications of relationship Relationship, he holds, must be determined on inborn, non adaptative structural characters He gives lists of such characters, but a careful analysis of his lists reveals the fact that the structures cited are those the functional significance of which is not apparent Is there any structure in the animal body which is devoid of functional significance and therefore free from adaptative changes?

The truth of a hypothesis is measured by the ease and naturalness with which it explains the multitude of facts which lie within a field of investigation When Prof Wood Jones rejects an anthropoidal stage in man's ancestry, he has to explain away a tremendous number of facts That the blood of man and anthropoids gives the same reactions when submitted to similar tests our author admits, but denies that similarity of reaction indicates a true 'blood relationship' of man to anthropoid Man and anthropoids have very similar susceptibilities to disease—a fact which is not discussed In recent years the existence of 'blood groups' has been demonstrated in all races of mankind The only other animals which possess corresponding group reactions are the anthropoid apes[1] Prof and Mrs Yerkes, in the great monograph recently published on "The Great Apes", demonstrate that of all animals the mental reactions of the great anthropoids are the nearest to those of man All these facts Prof Wood Jones has to explain away He has also to meet the fact that the further we trace man backwards in time, the more accentuated do his anthropoid characters become The skull cap of *Pithecanthropus* has been mistaken for that of a large gibbon, the lower jaw of Piltdown man had been claimed to be that of a chimpanzee, the molar teeth of Neanderthal man reproduces the dental pattern of the extinct anthropoid *Dryopithecus*, Rhodesian man rivalled the gorilla in the development of his supra orbital ridges All these facts run counter to Prof Wood Jones's scheme of man's evolution

The main criticism which must be made of this work is that it is not a full or fair statement of the great mass of evidence now available for determining man's evolutionary history and his relationship to anthropoid apes Nevertheless, it is a brilliantly written book, one which will serve a great and useful purpose in stimulating profitable discussion and further research A KEITH

Geology of Albania

Geologica Hungarica Fasciculi ad illustrandam notionem Geologicam et Palaeontologicam Regni Hungariae Series Geologica, Tomus 3 Geographie und Geologie Nordalbaniens, von Baron Fr Nopcsa, mit einem Anhange von H v Mžik Beitrage zur Kartographie Albaniens nach orientalischen Quellen Pp xiv + 703 + 35 Tafeln (Budapestini Edidit Institutum Regni Hungariae Geologicum, 1929)

NORTHERN Albania is a complex mountainous area which rises above the eastern coast of the Adriatic, where it bends abruptly from its course from north west to south east parallel to the grain of the country, and runs south, cutting across both the strike of the rocks and of the mountains Northern Albania occupies a critical position in the geology and geography of the eastern borderlands of the Adriatic and of the much debated Dinaric Mountains The geology of the country, according to the first accounts, appeared perplexing owing to the puzzling sequence of the rocks, which has now been explained by Baron Nopcsa, after field work extending from 1905 to 1925, as due to great overthrusts This view he has now established in a ponderous monograph, which is published as the third volume of 'Geologica Hungarica" by the Geological Survey of Hungary, of which the author was until recently the Director The most important previous contributions were those of Cvijic, whose work is dealt with briefly, and one of his misunderstandings is described as "catastrophal"

The oldest rocks in northern Albania are the Upper Carboniferous, as during all the preceding part of the Palæozoic, Albania was included in a great South Balkan land which was traversed by ancient mountains trending east and west This influence is still seen in the maintenance of that direction by some of the ranges and by the Curzola Lesina archipelago in the Adriatic The description of this land begins with the Upper Carboniferous, as marine rocks of that date occur on the North Albanian block (or Tafel) These beds are shown to be Uralian by their fossils, for example, *Productus cora* and *P uralicus*, and they are followed by Permian Neoschwagerina limestones. The Trias

was marked by a wide extension of the sea, and the deposition of dolomitic and massive limestones ranging from the bottom of the Trias to the Rhætic, these limestones are well represented in both the North Albanian block and the Cukali mountain complex to the south In the Ladinian (Middle Trias), volcanoes discharged sheets of tuff, a material which is now jasper, and ophiolites, which are well known from Steinmann's view of their formation by abyssal eruptions

The Jurassic is less well developed owing to extensive earth movements In the Lias, marine limestones and marls were deposited over much of the country, and after a break in the Middle Jurassic, more limestones were formed in the Upper Jurassic on the North Albanian block, and red flaggy limestones and radiolarite in Cukali In the south eastern part of the area the Jurassic is doubtfully represented by the basic igneous rocks which range from serpentine and peridotites to diabase, and cover most of the Merdita overthrust sheet

The Cretaceous is represented in the North Albanian block by massive limestones, but land still lay close on the south, for the system begins in the Merdita with a basal conglomerate, followed by sandstones and shales, and later, owing to the widening subsidence, by flaggy limestones and the massive Hippuritic limestones, which extend throughout North Albania

At the end of the Cretaceous further earth movements reversed the conditions In the Eocene the clearer sea lay to the south and south west, for the coastal ranges are formed of Nummulitic limestone, while in the North Albanian block are shales with fucoids and beds of flysch The coastal hills contain Oligocene conglomerates, with granite pebbles from the east, and clays with corals Then follows an important gap, and the presence in the mountains of highly disturbed Oligocene beds and of undisturbed Lower Pliocene shows that the main Dinaric folding was in the Miocene It extended the South Balkan land, which was reduced in the Pleistocene by widespread subsidences in some places to the amount of thousands of feet These movements broke up the land between Greece and Asia Minor into the Ægean Archipelago, enlarged the Adriatic, and produced the poljes in the Dinaric Mountains and the fiords on the Dalmatian coast

In a volume, "The Nature and Origin of Fiords" (1913), I described the adjacent parts of the Adriatic coastlands as a fractured belt, and interpreted most of the basins or 'poljes' as due to subsidence along faults, and claimed the Gulf of Cattaro as a true fault-formed fiord This conclusion was supported by a photograph (*op cit* Pl vi) of the block opposite Cattaro, which was described as of a fault-block, from evidence seen in a surreptitious visit, as the front of it was closed by military regulations This explanation has been denied, and the Gulf claimed as due to normal erosion Baron Nopcsa, however, marks a great fault along the very line shown in my illustration He fully proves the tectonic origin of many of the poljes and of features along this coast, and says that the faults are of such recent origin that the fault scarps are in many places very little worn

The Pliocene beds include in southern Albania the huge bituminous limestones in the Voyusa valley, near Valona, which are worked for asphalt, and, in association with some traces of petroleum, have encouraged the hope that among the folds of the Dinaric limestones may be a still hidden oilfield

The volume contains a detailed description of the geography and geology of North Albania, with a coloured map on the scale of 1 to 200,000, numerous sketch maps and diagrams which illustrate the complex tectonics due to overthrusts generally from north east to south west The volume is well printed, and is accompanied by twenty five clearly explained photographs of the scenery and geological structures by a bibliography which deals with the literature on the Albanian problems in other parts of the Balkans and Asia Minor, and an article by Hans v Mžik on Oriental contributions to Albanian cartography

J W GREGORY

The Polarity of Molecules

Polar Molecules By Prof P Debye Pp 172 (New York The Chemical Catalog Co, Inc, 1929) 3 50 dollars

Polare Molekeln Von Prof P Debye Pp viii + 200 (Leipzig S Hirzel, 1929) 14 gold marks

THE name of Debye is associated with many new and important theories in physics, but none of his theories has more successfully suggested, directed, or stimulated experiment, than his theory of dielectrics Since Debye's first paper on this subject in 1912, so many advances have been made, and so many new facts established, that an authoritative account of these developments from the pen of Prof Debye himself is particularly welcome

The English book is the outcome of a recent visit of Prof Debye to America, where he gave courses of lectures on the dielectric properties of matter and was induced to put the substance of

his lectures in more permanent form The book is concerned principally with the molecular interpretation of the dielectric constant and the correlation of dielectric properties with other physical properties such as dispersion and absorption, particularly in the infra-red At present, theory can deal adequately only with vapours, because, in fluids, the interaction of neighbouring molecules is too important to be neglected and cannot be estimated Methods of dealing with dilute solutions have, however, been developed recently, and these are described in some detail

In the simple theory it is assumed that dielectric phenomena are due to two causes first, to the distortion of the electronic structure of the individual molecules in the presence of an electric field, and secondly, to the fact that the electrical distribution of many molecules is unsymmetrical even in the absence of a field, such molecules are said to possess a permanent electric moment The magnitude of this electric moment is a molecular constant, which is as important, if not more important than other known molecular constants such as the size of a molecule, as it exercises a controlling influence on many physical phenomena The methods of determining this constant by a comparison of theory and experiment are described at length and, for the first time, the magnitudes of all known electric moments are brought together in accessible form, in fact, the German book, which is a revised and extended edition of the English book, contains a list of the electric moments of about two hundred molecules This table is to be extended still further and issued later as a special supplement

The table of electric moments is instructive Molecules which consist of two different atoms are non symmetrical and possess a permanent moment, while molecules like hydrogen and nitrogen, which are symmetrical, have none Nearly all triatomic molecules have permanent moments, and this result leads to important deductions as to the arrangement of the atoms in a molecule It shows that the atoms of the water molecule, for example, cannot be situated symmetrically along a line A chapter is devoted to a discussion of the possible forms of this and other molecules, and it is shown that the arrangement of H_2O is most probably triangular, while that of NH_3 is pyramidal This conclusion will not surprise the organic chemist, as, on other grounds, he has long ago postulated that the three valencies of the nitrogen atom are not directed in a plane

Considerable work is now being done on the relation between the dissymmetry of molecules (as reflected in their electric moments) and their chemical formulæ Recent advances are reviewed in the English edition, and more fully in the later German edition The effect of the substitution of two equal molecular groups in a carbon chain or in the benzene molecule depends essentially on the relative positions of the groups The trans form of dichloroethylene and the para form of dinitrobenzene both have small or zero electric moments, but the unsymmetrical isomers have large moments If the two substituted groups are not equal, a moment remains even in the para-compound, as is illustrated by the three nitrotoluenes Appropriate measurements of the polarity can therefore be used to determine the electropositive and electronegative character of various molecular groups It seems likely that it will be possible soon to estimate the polarity of a complicated compound by adding up vectorially the moments of the different groups which constitute the molecule

The later chapters are devoted to an account of the new wave mechanics in so far as it affects the theory of the dielectric constant and the theory of dispersion The first formula given by Debye for the dielectric constant was deduced from the classical theory and had to be modified when the quantum theory was first introduced, but the more recent forms of the quantum theory, expressed by the matrix and wave mechanics, have returned the formula to its original form, so that the older determinations of electric moments deduced from the classical formula still stand The book concludes with a theoretical discussion of the dispersion and absorption of polar gases, with special reference to rotating molecules of the HCl type It is shown that anomalous dispersion should occur in the region of long wave lengths, approaching radio frequencies, though experimental results in this region are, of course, still lacking The notation used is unusual and unfortunate (the rotational quantum number, for example, being denoted by *n*) and might with advantage be brought into line with that already used in molecular spectra

This book not only brings together for the first time the accumulated information on electric dipoles, but also points out the gaps which still exist in theory and experiment It is thus of great value to all physicists and chemists who are interested in molecular structure, and, in suggesting new fields of work, is of the greatest possible value to research workers in this and allied subjects J E LENNARD-JONES

Our Bookshelf

(1) *The Future of the Earth* By Dr Harold Jeffreys (Psyche Miniatures General Series, No 24) Pp 72 (London Kegan Paul and Co, Ltd, 1929) 2s 6d net
(2) *Earthquakes and Volcanoes* By Prof J W Gregory (Benn's Sixpenny Library, No 97) Pp 80 (London Ernest Benn, Ltd, 1929) 6d
(3) *The Restless Earth An Introduction to the History of the Rocks* By Prof Herbert L Hawkins (Routledge Introductions to Modern Knowledge, No 10) Pp iv+76 (London George Routledge and Sons, Ltd, 1929) 6d net

THE first of these "little books on great subjects" is considerably shorter than the other two and costs five times as much But in view of the facts that it will appeal to a much smaller circle of readers, is well bound and is printed on good paper, it cannot be regarded as overpriced, it is rather the others that are extraordinarily cheap

(1) Dr Jeffreys entertainingly summarises some of the theories more technically discussed in his larger book, "The Earth" He deals with the history of the sun, and the age and origin of the solar system the cooling of the earth and the 50,000 million years of cooling still before it, and the past and future of the moon The title of the booklet indicates only a point of view

(2) Prof Gregory's contribution to Benn's inimitable Sixpenny Library is tightly packed with good things In eighteen short but intensely interesting chapters, he surveys every important aspect of volcanoes and earthquakes, and it is safe to say that there is no better short account of these subjects available in English The book should have a big sale, and its influence on teaching in schools, as well as directly on the reading public, should go far to remove many current misconceptions The chapter on "The Inner Structure of the Earth" is, however, less up to date than it might be, it is certainly not in accordance with modern evidence to describe the shell between the rocky crust and the iron nickel core as consisting "mainly of the rigid nickel iron mass of the earth" It is much more likely to have a composition akin to that of stony meteorites

(3) Prof Hawkins is not altogether happy as a popular writer, despite the attractive vitality of his style The use of metaphor and analogy is sometimes far fetched and undignified Denudation is "grinding the dust" the interior of the earth is "beneath the dust", earthquakes are "shivering fits", and volcanic activity is "feverishness" When the author writes 'the earth is bleeding to—perfection", or water is more obedient [than the wind] to the call of gravitation", he runs the risk of irritating some of his readers Apart from this occasional defect of manner, the matter of the book is excellent, and the name of the author is a sufficient guarantee of its trustworthiness as a popular introduction to geology

Royal Agricultural Society of England Agricultural Research in 1928 Pp viii + 193 (London John Murray, 1929) 1s

THE Royal Agricultural Society has issued its fourth annual summary entitled "Agricultural Research in 1928" As in previous years the publication is divided into a number of reports, each written by an acknowledged expert in the particular subject

Fruit and vegetable canning, though a comparatively new industry, appears to have made a promising start and should provide excellent new markets for farm produce provided suitable organisation, including standardisation and grading, is built up The importance of obtaining a full and even plant in cereals and sugar beet is emphasised if the best yields are to be secured

Progress is being made in the production of tuberculin free herds of dairy cows, and the importance of progeny rather than ancestral performance in estimating the worth of a breeding animal is becoming more clearly recognised Farm costings of all kinds, including questions concerning marketing and co operation, are being thoroughly investigated The effect of the Agricultural Credits Act on insurance and credit is also dealt with Among engineering problems, drainage is receiving considerable attention, and recent trials in other countries, notably France, are described Of the newer implements, the combine harvester seems to have proved its usefulness in the English climate, provided that a drier is regarded as a necessary part of the equipment Methods for drying grain, grass, and sugar beet are also being developed

No outstanding new discovery is mentioned in the animal nutrition section, but the most recent views as to the nutritive value of grass, sugar beet pulp and tops, silage, and milk are fully discussed As regards fertilisers, nitrogen occupies the most important position, its world production and consumption having enormously increased during 1927–1928 Potash, on the other hand, shows only a small increase over previous years, and phosphorus none at all The success of Danish agriculturists in the production of feeding stuffs is attributed to their large increase of acreage under root crops In England, on the other hand, the reverse is the case The major portion of the report on veterinary science deals with vaccination against tuberculosis, and it is shown that the different types of tubercle bacilli are capable of infecting species other than those from which they take their name To each report a large number of references are appended, and the publication should prove useful to farmers, agricultural organisers, and students

The Theory of the Gyroscopic Compass and its Deviations By Dr A L Rawlings Pp x + 191 (London Macmillan and Co, Ltd, 1929) 10s 6d net

IT was about eighty years ago that Foucault carried out his ingenious experiments with the gyroscope, but for half a century the apparatus had no practical application It has now, however, been applied

to the automatic steering of torpedoes, to the mono-rail car, to the reduction of the rolling of ships, and to the steering of ships Of the gyro scopic compasses now in use, the Anschutz was the first, and this was followed by the Sperry and Brown compasses H M S *Invincible* was navi gated to the Falkland Islands, and the British Submarine *E11* found her way up the Dardanelles into the Sea of Marmora, by Sperry compasses, and such compasses are to be met with in every ocean

Handbooks on the gyroscopic compasses have been issued by the firms making the various types, but these do not deal fully with the mathematical theory involved Dr Rawlings has therefore attempted to place this theory in the reach of any-one with an elementary knowledge of the differen tial calculus His book is written primarily for those engaged in the construction of compasses and for navigators, to whom it should prove most useful The opening chapters are devoted solely to the explanation of the action of the compass, the restraints imposed upon the gyroscope so that it shall be of use, and the problems involved in its oscillation, its damping, and its stability After this there are descriptions of the Anschutz, Brown, and Sperry-Rawlings Harrison compasses, while the later chapters deal with compensating weights, rolling error, damping error, and gimballing error, and the accuracy of the gyro compass at sea

The Court of Burgundy Studies in the History of Civilisation By Otto Cartellieri Translated by Malcolm Letts (The History of Civilisation Series) Pp xv + 282 + 25 plates (London Kegan Paul and Co , Ltd , New York Alfred A Knopf, 1929) 21*s* net

THIS volume in the History of Civilisation Series is one of peculiar interest for English readers The Burgundian court was a great formative influence in the history of European culture The four dukes who united Burgundy and Flanders under their rule in the period extending from the middle of the fourteenth century to the end of the fifteenth, gathered around them sculptors, painters, scholars, and poets from all parts of Europe, while their court was the last school of the dying order of chivalry The rivalry of the houses of Burgundy and Armagnac gave England the opportunity of intervention But the alliance between the English kings and the Burgundian dukes, which was a dominating factor in the troubled politics of France, had an abiding effect on English culture By ensuring an outlet for our wool trade in the great commercial centres of Flanders, it confirmed the development of English rural life and industry along the lines which ended in the formation of the great pastoral estates, with subsequent economic and social consequences known to all Prof Cartellieri here deals with a subject which he has made peculiarly his own His book is no mere recital of political events, but in a very real sense a social history in which every aspect of life, art, and literature is followed in detail One chapter deals with the famous witchcraft persecution at Arras

Exact Colour Matching and Specifying By L Blin Desbleds Pp 116 (Paris Technological and Industrial Service, n d) 25 francs , 4*s*

IN this work the industrial method of accurate colour measurement, and consequently of matching colours, made possible by the use of Toussaint's photo electric photo colorimeter, is set forth, with many practical examples, in a clear way It will generally be dyers and those dealing with fabrics who will find it useful

The uncertainty that must always be associated with eye observations, because of the variations of colour sensitiveness even in the same eye, is eliminated by the use of a photo electric cell through which an electric current is passed and upon which impinges the light reflected by or transmitted through the substance the colour of which is to be measured The readings therefore are of the position of a spot of light on a scale, as customary in the use of a reflecting galvanometer The light that impinges on the sample passes through one or other of (generally) six Wratten Kodak monochromatic filters transmitting known wave lengths Violet, blue, green, yellow, orange, and red are appropriate colours, and the results are plotted on a prepared form of wave lengths as compared with the same light as reflected from a white surface of plaster of Paris, or better, as more uniform, barium sulphate, which is taken as 100 From these curves all the information required for practical purposes can be found by simple calcula tions, and these are fully illustrated The volume is a manual for use in the works' laboratory

In the Land of the Lion By Cherry Kearton Pp 256 + 60 plates (London J W Arrowsmith, Ltd , 1929) 10*s* 6*d* net

MR KEARTON is probably our oldest and best known African picture shikari Having given us ' Photographing Wild Life Across the World", in which he recounts many ' hairbreadth escapes ' and exciting incidents with denizens of the wild, the actions of which he tried to portray, he now presents us with a book to gladen the heart of the Nature lover, dedicated by the by to his wife, her-self an author of repute In its twenty short chapters the author has something to say about most of the animals of the African bush and many birds and insects The best, perhaps, is his chapter on the white ant Systematic natural history is not his strong point, but his light sketches of the doings, family life, and frolics of the larger animals, lion, elephant, giraffe, hippopotamus, rhinocerus, and many more, are excellent reading, and conjure up fascinating pictures of wild life in sun scorched bush, river, and swamp

The eighty eight illustrations are mostly photo-graphs from the author's film " Tembi ", in our opinion one of the best Central African films yet produced The magnificent photograph of equa-torial glaciers and snowfields up in the clouds and far away is alone worth the cost of the book, which is tastefully got up and supplied with an efficient index

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Grating Errors and Electronic Charge

AN investigation of the focal properties of small plane gratings has led to a discussion concerning the influence of grating errors on X-ray spectra obtained by means of plane gratings. It may be of some interest to give here a brief account of the results, as they are of some importance with respect to the accuracy of the value of the electronic charge deduced from X-ray measurements.

As is well known, a linear change of spacing along the grating gives rise to focal properties. Thus, the incident beam being parallel, the diffracted beam will be convergent or divergent according to the direction in which the spacing varies and the location of the spectral line with respect to the central image.

If, now, in the portion of the grating effective in the formation of the spectrum the spacing varies linearly only in *one* direction, this will be of no influence on the wave-length measurements, as the diffraction pattern (in the Fraunhofer case) is symmetrical and the principal maximum is in its proper position, that is, in the same position as the principal maximum of a perfect grating with a spacing equal to the mean spacing of the defective grating (see, for example, Sparrow, *Astrophys. Jour.*, **49**, p. 65, 1919).

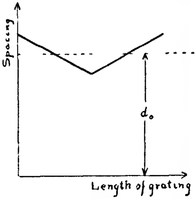

FIG. 1.

When, however, the effective portion of the grating contains certain regions where the spacing increases and other regions where it decreases along the grating, this may cause asymmetry and misplacing of the spectral lines.

A simple mode of demonstrating this is the following. We may, for example, assume that the spacing of the grating varies as in Fig. 1. Thus there is one portion of the grating where the spacing decreases linearly, and another, adjacent and equal in width, where it increases at the same rate along the grating. The diffracted beam from one portion will therefore converge to a real focus, and that coming from the other portion will diverge from a virtual focus behind the grating (see Fig. 2). Thus the maximum intensity will be shifted in relation to the central beam of the bundle. A more detailed communication, where this point of view will be more closely discussed, will be published in *Zeitschrift für Physik* shortly. In each case the only method which is without doubt entirely free from objections is the *exact* calculation of the diffraction pattern, but this is a work of some difficulty for the less simple geometrical conditions of the X-ray spectrographs.

Now all gratings ruled with the aid of a screw are affected with periodical errors, where the period of the error is equal to the pitch of the screw. When the number of periods in the effective portion of the grating is large, we know from theory and experiment that ghosts will occur in the spectrum ('Rowland ghosts'). When, however, the number of periods is *small*—this

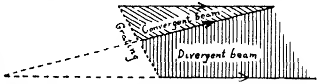

FIG. 2.

being the essential point in this account of the conditions—we may anticipate asymmetries of the kind above described.

As the pitch of the screws used in the common ruling machines is about 1.2 mm. and the length of the effective portion of the grating is about 2.3 mm. in the case of the experimental arrangements of the X-ray measurements considered, it is clear that the number of periods is small and that the risk of asymmetry of the spectral lines really exists. (As a matter of fact it is *necessary* to work with small portions of the grating in order to avoid the correction originating from lack of parallelism of the beams. See Porter, *Phil. Mag.* (7), **5**, p. 1067, 1928.)

In order to get some quantitative account I have calculated the diffraction pattern (in the *Fraunhofer case*) for the case shown in Fig. 1. The result is given in Fig. 3. The total number of lines in the grating is about 160. The *maximum* misplacing of a line (the misplacing at the ends and in the middle of the grating) in reference to the lines in a *perfect* grating of grating constant d_0 is 0.12 d_0, where d_0 is the mean spacing of the defective grating. Fig. 3 gives the amplitude as a function of wave-length. The vertical line denotes the position of the principal maximum for a perfect grating of grating constant d_0. Thus the principal maximum of the defective grating is shifted (in this special case about 0.0015 λ), and the distribution of intensity in the total diffraction pattern is asymmetrical.

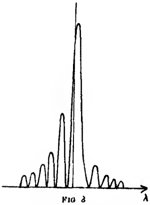

FIG. 3.

A general calculation of the shift of the principal maximum (in the conditions illustrated in Fig. 1) gives the following result:

$$\text{Error of wave-length } (a) = \frac{2\, m_{\max}}{l} \lambda$$

where m_{max} is the *maximum* misplacing of a line in the grating and l is the length of the grating

For $l = 1$ mm we get

if $m_{max} = 0\ 0005$	mm	$a = 0\ 001\ \lambda$
,, $= 0\ 00025$	,,	$a = 0\ 0005\ \lambda$
,, $= 0\ 0001$	,,	$a = 0\ 0002\ \lambda$

The X ray measurements considered are, as said above, of considerable interest on account of their importance as regards the value of the electronic charge (e) Now a certain error in the wave length gives rise to an error in e three times as large From the above discussion it appears that the error in e originating from the grating errors is very likely to amount to values comparable to the total error in e stated by some authors The object of this paper is thus to direct attention especially to the fact that the quality of the grating is of decisive importance to the accuracy of the value of e deduced from X ray measurements

New Types of Emission Spectra

THE emission spectra which we observe in the visible and ultra violet region are divided into line and band spectra, of which the first type corresponds to electronic changes of state of single atoms either in neutral or in an ionised state The band spectra originate from molecules, and the energy quanta emitted in a certain spectral line draw their energy from three sources (1) change of electronic orbits, (2) change of vibrational energy, and (3) change of rotational energy

The study of the luminescence from solidified gases at very low temperatures has revealed a new type of spectra, which is a combination of electronic jumps and atomic oscillations, and we obtain a type of vibrational band spectra free from the influence of rotational energy Since their discovery in 1924 (*Comm Lab Leiden*, No 175) a considerable number of spectra of this new type has been studied, and numerous lines have been classified into vibrational series and systems of such series (See, for example, *Ann d Phys*, **79**, 1926, and *Comm Lab Leiden*, No 183, 200, and Suppl No 59)

Now it appears that most of the series are not composed of single lines, but of two or more components This splitting up of the lines is more pronounced at the temperature of liquid helium than at that of liquid hydrogen and for such series which appear strong in the afterglow spectra, and are undoubtedly emitted from matter in the solid state The multiplicity of lines is therefore not due to rotational energy

It might, then, at first sight seem reasonable to ascribe the splitting up of the lines to a multiplicity of the electronic terms Following up this idea, however, we meet with the difficulty that series with quite different electronic terms and different principal vibrational frequencies show very nearly the same frequency difference between successive components Thus the series called C, D, and E show a separation of about 45 cm $^{-1}$, and about the same difference is found for the doublets of the ϵ system In the case of the principal series of the ϵ system (the η series), we find, under certain conditions, that the 'lines' are split up into 4 7 components, with an approximately constant difference between successive components of about 40 cm $^{-1}$ The a series gives a separation of 69 cm $^{-1}$ A multiplicity of this type cannot be accounted for by the theory of electronic terms

Now the a-form of solid nitrogen was shown (*Zeits f. Phys.*, **58**, 497; 1929 NATURE, Aug 17, 31, 1929) to have a pronounced molecular structure, and the atomic distance and dissociation energy of the molecular elements of the lattice were found to be approximately identical with those of the gaseous molecules The ordinary oscillatory series correspond to atomic oscillations of the atoms of molecular elements in various states of electronic excitation The strong binding between the two atoms of a molecule corresponds to the high principal vibrational frequencies of the order of magnitude 1200 2400 cm $^{-1}$ But a molecule with vibrating atoms may itself be vibrating on account of the forces which bind the molecules in the crystal lattice, and which are closely related to the elastic forces of the crystal

As the distance between the molecules is much greater than that between the atoms of a molecular

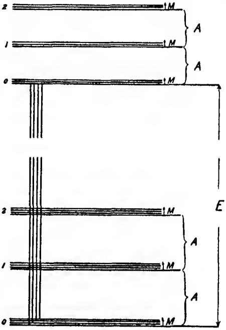

FIG 1
E—Change of energy of electronic states
A—Change of energy of atomic vibrations
M—Change of energy of molecular vibrations

element, it is to be expected that the internal state (either electronic or vibrational) of the molecule will have little influence on the molecular vibrations, and thus we may understand that the separation of lines on account of molecular vibrations may be approximately the same for series corresponding to different internal states of the molecular elements

Thus we are dealing with a type of spectrum where the frequencies are modified from the following three causes (1) Change of electronic states (2) Change of vibrational energy of the atoms of a molecular element (3) Change of vibrational energy of the molecular elements in the crystal lattice

The formation of a spectrum of this type is shown in Fig 1

Recovery from Parasitism

THE pine shoot moth, *Evetria buoliana*, Schiff, one of the best known Lepidopterous pests of young Scots pine in Europe, has during the past decade been causing much concern by its increasing prevalence in the numerous young pine plantations in East Anglia Just over a year ago a thorough study was begun of

the biology and forest relations of the species, the first results of which have been worked out Amongst other things it has been found that a slight check is exercised on the increase of the insect by a number of different species of parasites which oviposit in the newly hatched caterpillars and the flight periods of which correspond roughly to that of the moths, and in this connexion an interesting fact has already been brought to light

Caterpillars collected from different areas were bred out either to the adult moths or to parasites, and it was found that those which came from areas in which the percentage internal parasitism of the caterpillars was high, yielded some fertile moths which were much smaller than the 19 mm wing span given by Meyrick[1] as the minimum for the species From others which came from areas in which the percentage parasitism was low, such small moths were extremely rare For example, from 300 caterpillars parasitised to the extent of 80 per cent, 7 per cent of the emerging moths had a wing span ranging from 13 mm to 17 mm, while caterpillars parasitised to the extent of 70 per cent only gave about 2 per cent moths of the small type, and from caterpillars with a percentage parasitism of less than 60 per cent, only two small moths were bred out as against more than 400 of the normal type

In considering the significance of these results, it has occurred to me that the prevalence of these small moths may be connected in some way with the high percentage of internal parasitism and that they may possibly be the results of a recovery from parasitism

Recovery from parasitism by phagocytosis of the parasites' eggs or newly hatched larvæ has been described in detail by Timberlake,[2] and such recovery has been noticed occasionally in the young caterpillars of *E buoliana* but appears to have no effect on the ultimate size of the adult moth In the present case the results so far obtained tend to show that recovery probably takes place at a later stage in the life history

Tothill[3] has pointed out that the active histolysis which takes place in the pupal and prepupal stages of a moth renders them unsuitable feeding grounds for those internal parasites which are devoid of some means of protection such as a trophamnion It is easy then to imagine that if for any reason the development of a normal internal parasite was delayed until the host reached the prepupal stage, the parasite larva would be attacked by the active phagocytes, broken down, and its substance probably built up into the tissues of the adult moth

Such retardation of the parasite larvæ was often noted when super or multiple parasitism occurred Caterpillars containing two or more living first stage parasite larvæ which would have taken well over a month to develop, were found less than three weeks prior to the date of the last recorded emergence of the parasites That these parasites would have emerged is highly improbable, and one must suppose, therefore, that in such cases there would be either a recovery from parasitism, or that total death by mutual exhaustion of the complex would have taken place

The caterpillars are, however, only slightly retarded in their development by the presence of internal parasites, but after the first instar are invariably found to be smaller both in general bulk and in the measurements of the head capsule than unparasitised specimens of the same stage This makes it impossible to apply Dyer's law for the separation of the stages, to any but unparasitised individuals From the above evidence it seems probable that a recovery from parasitism has taken place in the prepupal or pupal stage of the moth

The type of small pupæ from which these moths emerged also showed a greater percentage mortality than the normal type, and if the hypothesis advanced is correct, it is natural that after a severe drain of blood plasma from the feeding of the parasite larvæ their vitality should be lowered

No direct evidence of this recovery has been noted in the small amount of preserved material yet examined, but this need not be taken as negative evidence The actual process may be very rapid, and as it only occurs in a small percentage of the caterpillars at a stage not yet definitely known, many hundreds of futile dissections may have to be made before one can expect results

If it can be definitely established that recovery from parasitism can take place as suggested at a later stage in the host's life cycle, it may throw light on many details of parasitic (internal) control of pests in general and account for their usual incompleteness in exterminating a host It is generally considered that 100 per cent parasitism brings about total extinction, but such a percentage would involve a large proportion of supernumerary parasites which, causing mutual retardation, would allow a large percentage recovery of the host In all probability the maximum mortality will occur when the host has a percentage parasitism of less than 100, but this maximum will never be 100 per cent in hosts in which such recovery occurs C CRAWSHAW BROOKS

Occurrence of *Craspedacusta* (*Limnocodium*) *Sowerbii* in the Exeter Ship Canal

DURING the summer of 1928, while collecting Crustacea and other forms of fresh water life in the Exeter ship canal, I had the good fortune on July 21 to find in a hand net gathering, made midway between the Turf Hotel and Topsham ferry boat landing, two small medusæ quite new to me These I preserved, and later sent them to Mr Edward T Browne, who identified them as *Craspedacusta Sowerbii* A short time later, Mr Browne kindly sent me a tow net, but the great difficulty then was to get a boat However, I succeeded in obtaining more than a hundred specimens, ranging from early stages up to the fully grown adult The medusa was present in the canal up to Sept 8, when some early stages were taken During the past summer (1929) I have been more successful, and have been able to get a suitable punt whenever I wanted one

My studies in this interesting medusa have not been so complete as I could have wished, but I have published these notes in the hopes that others younger than I will be attracted to study the fresh water life in this interesting canal

According to Mr P C De la Garde—"On the Antiquity and Invention of the Lock Canal of Exeter" in a letter from Philip Chidwell de la Garde, to Sir Henry Ellis, F R S, Secy Read Jan 11, 1838 From *Archæologia*, 5, 28—the Exeter ship canal was completed about the year 1698 so far as Topsham "In the year 1829", writes Mr de la Garde, " it was extended to Turf It is now upwards of five miles and a half in length It has two entrance locks, one at Turf and another opposite Topsham Between these and Exeter it has only one lock, the old double

lock altered and improved. The Canal is 34 feet wide at the bottom, and 94 feet at the surface of the water, with 15 feet of water throughout."

This fresh-water canal, which receives its water from the River Exe, teems at certain seasons of the year with an abundance of microscopic life. Besides fish of various species, *Paludina vivipara* and *Dreissena polymorpha*, two most interesting molluscs, are always present; while *Cristatella mucedo* can be found in the higher parts of the canal; *Plumatella repens* and *Cordylophora lacustris*, near the Topsham lock gate.

It is interesting to record that, up to the present, I have been unable to make one addition to the lists of fresh-water Crustacea recorded by Canon Norman and Thomas Scott in "The Crustacea of Devon and Cornwall."

Owing to ill health, I was unable to commence my fresh water collecting until July 8 last, when no medusæ were to be found. My next collecting trip was made two weeks later, when I found the medusæ plentiful. Surface temperature 65° F. From that date until Oct. 14, medusæ were present in varying numbers. On Sept. 5 the surface temperature was 72° F. and the canal was found swarming with medusæ; they were so abundant that one could see them with the naked eye. From that day until the fall of the year, the medusæ gradually decreased in numbers. On Oct. 1 not more than twenty medusæ were caught, surface temperature being 60° F.; and on Oct. 14 they vanished for the year, surface temperature being 57° F. Although I have collected at various points along the whole canal, I have not found any medusæ above the double lock.

According to my observations there appear to have been at least four distinct broods of medusæ in the canal during the past summer on or about the following dates: July 20, Aug. 24, Sept. 5 and 19.

All the specimens taken were males, and a special search was made for its hydroid, known as *Microhydra*, without success, but it must be somewhere in the canal.

Both the hydroid and its medusa have been found in streams and ponds in the United States, but this is, so far as I know, the first time the medusa has been taken under natural conditions in Europe, where it has been found under artificial conditions; usually in warm water tanks belonging to botanical gardens.

Magnetic Moments of Atomic Nuclei

THE hyperfine structures of atomic spectra are considered as due to the interaction of the nuclear spin with the electronic orbital and spin moments. A theoretical calculation of this interaction enables one to obtain information on the magnitude of the magnetic moments of the nuclei from the separation of the hyperfine structures. This can be done for the case of the alkali atoms. Hargreaves (*Proc. Roy. Soc.*, **124**, 568; 1929) has calculated the separation due to a nuclear moment $h/4\pi$ for the case of atoms with only one electron. In his calculations, however, the interaction between the electronic and nuclear spins, which is of the same order of magnitude as the other terms, has been neglected. I have therefore carried out the calculations with the following improvements. For the s terms, which is the most important case, since they give the largest contribution to the separation, I have used Dirac's theory of the electron, since the simpler Pauli's theory gives a wrong result. For the p-terms I have used Pauli's method, taking into account the interaction of the nuclear and electronic spins. For the p-terms it is not necessary to evaluate numerically the eigenfunctions, since the constants involved in the formulæ can be derived from empirical data on the separation of the electronic spin doublets. For the s terms this is of course impossible, and I have calculated the eigenfunctions by the statistical method.

If the mechanical and the magnetic moments of the nucleus are respectively $kh/2\pi$ and μ_0, one finds that the s terms split into two components with a separation

$$(1) \qquad \Delta = \frac{2k+1}{k} \cdot \frac{8\pi}{3} \mu\mu_0 \psi^2(0),$$

where μ is Bohr's magneton and $\psi(0)$ is the value of the normalised eigenfunction at the origin. The separation of the p terms is much smaller. Each line of the principal series of the alkalis splits, therefore, into two components with the separation Δ, each of them having a finer structure, which is not resolved, and gives rise to small differences in the observed separation for the different lines. The ratio of the intensities of the two components is $(k+1)/k$, the weaker component being shifted towards the violet. The ratio of the intensities is also 3, 2, 5/3 ... 1 for $k = 1/2, 1, 3/2$ ... ∞.

For cæsium one finds, in wave numbers,

$$\Delta = 146 \frac{\mu_0}{\mu} \frac{2k+1}{k},$$

and for sodium

$$\Delta = 13.4 \frac{\mu_0}{\mu} \frac{2k+1}{k}.$$

The observed values are, for cæsium (D. A. Jackson, *Proc. Roy. Soc.*, **121**, 432; 1928) $\Delta = 0.3$, and for sodium (H. Schuler, *Naturwiss.*, **16**, 512; 1928) $\Delta = 0.06$ wave numbers. From this, on the assumption of the values 1/2, 1, 3/2, ..., ∞ for k, we obtain the following values for the ratio μ/μ_0 of the Bohr magneton to the magnetic moment of the nucleus:

$k =$	1/2	1	3/2	∞
Cæsium	1950	1460	1300	980
Sodium	890	670	600	450

From the observed ratio of the intensities in sodium one should expect a probable value for k of 1 or 1/2.

The uncertainty of the given values arises from the lack of precision of the empirical data and from the application of the statistical method to the evaluation of the eigenfunctions. This latter source of error might be evaluated to within 20 or 30 per cent.

Further details will be published later.

Optically Active Diphenylethylene Oxide

WE have recently been able to obtain optically pure *d*- and *l* *iso*hydrobenzoin, Ph.CH(OH).CH(OH).Ph, by the action of nitrous acid on *d*- and *l*-*iso*diphenylhydroxyethylamine (*Jour. Chem. Soc.*, 1929, 2305). This result might be considered to point to configuration (ii), rather than (i), for *iso*diphenylhydroxyethylamine, except for the circumstance that *l*-*iso*hydrobenzoin is furnished in this way by *d*-diphenylhydroxyethylamine as well as by the *l*-*iso*base.

(i)  (ii) 
In order to settle the ambiguity, we have now prepared specimens of 2 : 3 diphenylethylene oxide from each of these bases, through the quaternary ammonium hydroxides, Ph.CH(OH).CH(NMe$_3$OH).Ph. The

optically active and externally compensated forms of the *iso*base yielded an identical optically inactive diphenylethylene oxide, which therefore corresponds to the *cis* configuration (iii), with a plane of symmetry (indicated by the broken line) *d* Diphenylhydroxyethylamine, however, gave a strongly lævo rotatory oxide, to which the *trans* configuration (iv) must be assigned It follows that the relative molecular configurations allocated to the above bases by Erlenmeyer in 1899 must be reversed, the base and the *iso*base being represented by (ii) and (i), respectively We propose to explore further this valuable general method for determining the relative molecular configurations of such substances

The stereoisomeric diphenylethylene oxides present several features of unusual interest

(iii)  (iv) 
The *trans* form (iv) is an example of the simplest type of cyclic structure which can give rise to dissymmetry of molecular configuration it will be noticed that the assemblage of five single atoms carrying two identical radicals still displays axial symmetry, although a plane of symmetry is no longer present These simple structural constituents may be compared instructively with the four single atoms and one group of the simplest known acyclic dissymmetric compound, chloroiodomethanesulphonic acid, that is, CHClI SO_3H The specific rotatory power of the *l* form of the above oxide (iv), observed in absolute alcohol for sodium light, exceeds $-300°$, while the corresponding value for *l iso*hydrobenzoin (its configurational analogue) is only $-92°$ thus, the optical effect of the 3 membered ring is strikingly apparent The extraordinary stability of these well defined crystalline oxides is in keeping with the views of Thorpe and Ingold on the effect of substituents in relieving the strain inherent in small rings

Other compounds of the same general type which we are at present investigating exhibit an equally pronounced stability, among them, the *cis* form of 2 3 dianisylethylene oxide has been obtained by the direct interaction of nitrous acid and the corresponding dianisylhydroxyethylamine, as well as from the same base by the general method indicated above Details of these studies and of further work directed towards the preparation of optically active ethylene oxides, containing aromatic or aliphatic substituents, will be published elsewhere

Do Oceanic Plankton Animals Lose Themselves?

RECENT researches into the behaviour of plankton animals in the sea as to their vertical movements from day to day indicate that light intensity is an important factor The animals appear in Nature to be brought around an optimum intensity by some tropistic mechanism and, assuming this, there seems likely to be a lower limiting or threshold intensity below which no stimulation takes place Such, indeed, appears to be the case at night with animals living in our shallower offshore waters, when, with the release of the light stimulus in darkness, they are free to roam anywhere and become evenly distributed throughout the water layers, within the limits of other controlling factors such as temperature and salinity This lower threshold intensity idea receives support from a paper published in 1926 by two Japanese workers, M Tauti and H Hayasi (*Jour Imper Fisher Instit*, Tokyo, vol 21, No 4, p 42), who found that if a light be projected at night vertically downwards into the water, fish swimming in numbers deeper in the water are only attracted individually to the light when by random movements they swim upwards into a certain threshold intensity

In view of these observations, the suggestion arises whether certain plankton animals which normally live in light of moderate intensities near the surface, but are to be found also in the deep, dark layers of the open ocean, are not, so to speak, lost in these latter layers Have they moved out of their normal light zone, perhaps at night, and reached layers at which the intensity is below the threshold, thus to be doomed to everlasting night until perchance by random movements one bright day they swim once more into the threshold intensity zone and are attracted upwards to their optimum intensity ?

Magic Square of Fifth Order

I VENTURE to send you what I believe to be a very rare magic square of fifth order Although there are more than 260,000 bordered squares of fifth order with the number 13 in the centre of the square, it seems a very rare thing indeed for any other number than 13 to be in the centre I have not found any with the

23	20	10	4	8	
22	2	16	18	7	36/29
14	13	17	6	15	Magic
5	21	3	12	24	number 65
1	9	19	25	11	

usual proportion (39/26) between the Row of the Heart and the rest of the Row, and it was not until the proportion 36/29 arrived that I found it was possible to make one I append the square Subtracting each number from 26 will give the proportion 42/23 I believe there are only two (not including inversions) with 17 in the centre of the square

Legitimate Uncertainty

ADVANCE of inquiry into fundamental tracts of Nature is often perforce conducted by means of symbolism The comprehensive character of the symbols counts for increase of knowledge, even though their physical interpretation is still shrouded in uncertainty Thus it is that, for example, Prof Eddington, on page 291 of "The Nature of the Physical World", amusingly sums up our present knowledge of electronic operations inside atoms by saying "*Something unknown is doing we don't know what*—that is what our theory amounts to" Similarly the sentences quoted from one of my books, at the end of a review on page 942 of NATURE for Dec 21, should be understood, not as a hopeless and helpless admission of ignorance but as a scrupulously fair and cautious stage in the advance of knowledge, for it is no gain to science to attempt the formulation of a nascent theory prematurely

OLIVER LODGE

Cycles in Natural Phenomena.

IN December 1922, Dr Merriam, president of the Carnegie Institution of Washington, called a conference to discuss the question of 'cycles' The report of this, and of a second conference held in December 1928, have now been published by the Carnegie Institution,[1] and the two reports form a stimulating contribution to the subject The members took a very broad view, which was set out by F E Clements in an introductory paper as follows "It seems desirable to use cycle as the inclusive term for all recurrences that lend themselves to measurement, and period or periodicity for those with a definite time interval, recognising, however, that there is no fixed line between the two On this basis there can be no question of the existence of climatic and other cycles, though there may be the gravest doubt of the reality of periodicities in climate beyond that of the year "

The greatest emphasis naturally falls on cycles of climate, which underlie most known cycles of other terrestrial phenomena, such as crops and prices, growth of plants, and fluctuations in numbers of animals, while climatic cycles are themselves most probably reflections of cycles of solar activity Unfortunately, however, the systematic observation of climate is of comparatively recent growth, and very few homogeneous series of meteorological records exceed one hundred years This is sufficient for the accurate study of weather periodicities of a few years in length, but is quite inadequate for the determination of longer cycles, from twenty or thirty years upwards The meteorological records, for example, have hitherto proved insufficient to determine the real nature and extent of the well known Bruckner cycle of about 35 years

On the other hand, there exist several natural agencies which have the power to integrate the meteorological conditions during a period of a few months or a year, and register the results in some permanent form The two most notable of these agencies are trees, which by the width of their annual rings show their rate of growth during each of a long succession of years, and melting glaciers, which leave behind them records of the volume of thaw water

The investigation of the annual rings of trees has found its home in the United States, where it is associated especially with the name of A E Douglass, who in 1922 was able to present conclusions based on the dating and measurement of more than 110,000 rings in nearly 500 trees, all carefully collated and compared It has been generally accepted that in the dry climate of Arizona and California the redwood, *Sequoia*, grows most rapidly in relatively rainy seasons, but the nature of the relationship between tree growth and weather is examined more closely in a paper read at the 1928 conference by O T MacDougal Since 1918, MacDougal has been obtaining measurements by means of the 'dendrograph', an instrument which makes a continuous record of the diameter of a tree between two contact points on opposite sides of the trunk

The trees chiefly examined were the Monterey pine and the coast redwood From the records illustrated, it seems that the pine grows most rapidly in late spring, the tree forms no reserve of starch, and in a dry situation the growth is closely related to the rainfall of the preceding winter If abundant soil moisture is available, however, growth is greatest in dry years with few fogs, abundant sunshine, and high temperature The meaning of the record made by the pine, therefore, depends on its situation On the other hand, the redwood accumulates a reserve of starch, and moreover, it grows only in situations where the soil moisture does not fall below a certain percentage Hence the correlation between the width of the annual rings and the rainfall in individual years is smaller than with the pine, but the redwood gives an excellent measure of the long period fluctuations of rainfall It also seems probable that temperature plays a more important part in the growth of the redwood than that of the pine

On the whole, the pine is probably the better index of rainfall, but it is relatively short lived Four of the Sequoias measured began their existence more than 3000 years ago, but few pines go back more than 500 years, the oldest covering a period of 640 years This difficulty has been partly overcome by the use of historic and prehistoric material, and the available pine records now cover two nearly equal periods, totalling about 1255 years, but unfortunately separated by a gap of unknown duration When this gap has been filled, the whole series will become a continuous climatic record of the highest value

The harmonic analysis of a very long series of data is a laborious occupation, and for the purpose of studying the variations of his tree measurements, in 1913 Douglass invented an ingenious optical instrument for determining the lengths of periodicities A large instrument with photographic attachment was constructed with a fund given by Mr Clarence G White, and the instrument has been termed the 'White Cyclograph' The earlier form suffered from the disadvantage of a rather limited range, the longest periodicity which could be determined being only seven times the shortest, but in an improved form described at the 1928 conference a device is incorporated which more than doubles this ratio The principal result obtained up to the present is that most of the cycles of growth shown by the western tree-rings are probably simple fractions of a Brückner cycle of 34 years

Another series of data which may prove of value is that relating to waves of infectious diseases, discussed by Dr W C White These may be related to cycles of solar radiation of various wavelengths, but very little is yet known as to the nature of the relationships, and the conclusion

[1] "Reports of the Conferences on Cycles" Pp 88 (Washington, D C Carnegie Institution, 1929) Free on request.

reached is that there is a greater likelihood that a knowledge of weather cycles will help the study of preventive measures against disease than that a knowledge of the history of epidemics will further the study of weather cycles

The view has often been expressed that by far the greater number of weather cycles will prove to be intimately related to cycles of solar variation Unfortunately, only one of the latter can be regarded as fairly established, namely, the double sunspot period of 22½ years The shorter cycles which are believed to exist in solar radiation are not well shown by the sunspot numbers, and reliable measurements of solar radiation do not yet cover a sufficiently long period to give conclusive results At the second conference, C G Abbot presented the results of the harmonic analysis of 100 months of data ending in October 1928, but probably the only periodicity so found which has any claims to reality is that of 25 months (an inspection of the author's diagram suggests that the real periodicity is slightly longer, perhaps 26 months) It seems that we shall have to wait many years for a full study of the periodic variations of solar radiation based on a sufficiently long series of observations

The greatest mass of material awaiting systematic periodogram research is to be found in the deposits left by the waters issuing year after year from the ends of the glaciers These waters deposit a fine clay, but the winter deposit, when the glacial streams are at a minimum, differs in colour and texture from that of the streams swollen by the summer thaw Hence the layer added each year can be readily detected and its thickness measured, giving what is essentially a representation of the average summer temperature These glacial deposits have been carefully studied by de Geer, Antevs, and others in Scandinavia, Finland, North America, the Argentine, and the Himalayas, and in Scandinavia it has proved possible to connect up the deposits with those forming at the present day and so obtain an accurately dated series of measurements covering a period of more than 20,000 years

Hitherto, statisticians have quailed before the immense task of analysing this record for periodicities, and in his paper Antevs quotes only two determinations, both rather casual In the Argentine series periodicities of 5 1, 10 4, and 51 years were found, while in the North American series there is a strongly marked periodicity of two years, besides others of three to eight years Neither investigation discovered the eleven year sunspot cycle, a remarkable result which is at variance with the claim of de Geer, embodied in his title ' the solar curve ", that the series of clay thicknesses is a measure of the variations of solar radiation from year to year

This does not exhaust the possibilities of wresting from Nature detailed evidence of her past vicissitudes Peat bogs in many countries enshrine the history of post glacial vegetation, and though by its nature this record cannot be made to give numerical annual values comparable with those from the trees or the glacial clays, it should—when it is fully understood—provide valuable information as to the longer sweeps of climate, which will form a base line for the variations of shorter period revealed by the more detailed sources

From the reports as a whole, it appears that on all sides forces are being marshalled for a combined attack on the weather changes in post glacial times, which cannot but throw much light on the changes in process at present As Dr White phrased the problem in the discussion, ' Surely it should be possible by careful planning and co-ordinated study to construct relatively complete records from the present year backward into Pleistocene time, though that is but a beginning of the baffling if not insuperable task of constructing a continuous record that will reach back into the Tertiary " C E P B

Recent Work on Yellow Fever

THE opening address of the Cambridge Philosophical Society on Nov 11 last was delivered by Prof E Hindle, the Beit research fellow in tropical medicine, who gave an account of recent work on yellow fever The paper for the most part was a description of experiments on yellow fever which have resulted in his discovery of a method of vaccination against this disease

West Africa is now the main endemic centre of yellow fever, although serious epidemics have occurred in Brazil during the year 1929 A new era in the study of the disease was opened by the discovery in 1927 by Stokes, Bauer, and Hudson, that Asiatic monkeys, and especially *Macacus rhesus*, can easily be infected with yellow fever Afterwards, Dr Adrian Stokes working at Lagos, and also Drs Young and Noguchi at Accra, died of yellow fever acquired in the course of their investigations Prof Hindle described how he succeeded in getting the virus of the disease brought back to London Pieces of the liver of an infected monkey in Senegal, killed at the height of the disease, were kept frozen during the voyage to London, a period of 12 days, and with this material the disease was reproduced in England at the end of March 1928 Since that date, the strain has been maintained by Prof Hindle at the Wellcome Bureau of Scientific Research and has been distributed to laboratories in Paris, Berlin, and Amsterdam The method consists of keeping the virus frozen, in which form it will survive for three to four weeks, or preferably to dry infected blood or tissues *in vacuo*, and keep it in the presence of a desiccating agent, when the virus will survive for 3-4 months Monkeys can easily be infected by the inoculation of blood or liver from an infected animal, and 1/1000000 c c of infected blood has been found sufficient to produce infection

Transmission experiments with both Indian and West African races of *Aëdes ægypti* (*Stegomyia fasciata*) reared in England have shown that the disease can easily be transmitted from infected monkeys to normal animals by the bites of these insects, on condition that an interval of at least 9 days at 28° C is allowed to lapse after the infective feed During this incubation period the virus has been found to be constantly present, not only in the gut, but also in the cœlomic fluid, as determined by inoculation experiments into susceptible monkeys Once infected, a mosquito remains infective for the duration of its life, and, moreover, it was found that this infectivity persists even if the temperature is continually below 18° C Formerly, it was supposed that the distribution of the disease was restricted by the mosquito being unable to transmit the infection below a certain temperature, but Prof Hindle's experiments show that this view can no longer be maintained The results of experiments with the Indian race of *Aëdes* constitute the first proof that they are capable of transmitting yellow fever, and it is evident that if, by any ill chance, this disease ever reached the Orient, the local race of mosquitoes could serve as efficient carriers

It has been know from early times in the history of the disease that an attack is followed by a high degree of immunity, and the serum of convalescent patients, if inoculated into monkeys, will protect them against infection for a period of about one month The presence of active immune bodies in the blood of recovered patients furnishes a means of finding out whether a person has had the disease, for it is only necessary to inoculate a rhesus monkey with the serum of a suspected case and at the same time with yellow fever virus Employing these methods in West Africa, the Rockefeller Commission had detected the existence of yellow fever in villages where no obvious signs of the disease were present

Employing these methods, the nature of two atypical cases of yellow fever contracted in the laboratory in London was discovered In both patients (Prof Hindle and his laboratory attendant), the symptoms, a sharp fever of short duration, closely simulated, and at the time were attributed to, influenza After the fever, however, in both cases the blood contained immune bodies against yellow fever, as tested by inoculation into monkeys, and therefore there can be no doubt that they had both had an attack of this disease

It may be added that jaundice and albuminuria, although looked for, were not detected, and the only characteristic symptom was hyperæsthesia of various parts of the body in one patient which persisted for 3 to 4 weeks These results, combined with the production of immunity by the inoculation of sub lethal doses of virus, furnish additional evidence in support of the view that mild cases of yellow fever may occur which present none of the ordinary symptoms of the disease These cases would never be recognised in the ordinary course of events, but would be capable of infecting mosquitoes that fed on them and thus maintain the infection in a latent or hidden form

An interesting case of tissue immunity was described The liver and spleen of monkeys that have recovered from yellow fever, when inoculated into normal monkeys in 1 gm doses, immunised them against subsequent inoculations of fresh virus The brain, kidney, and lymphatic glands of convalescent monkeys did not possess this property The inoculation of hyperimmune serum into infected monkeys, after the commencement of fever, had no obvious effect on the course of the infection, and consequently there is doubt as to the value of serum treatment in human cases of yellow fever

Great hopes had been placed on Noguchi's vaccine prepared from *Leptospira icteroides*, erroneously supposed by him to be the causative organism of yellow fever It is now known that this organism is identical with that of spirochætal jaundice, therefore the vaccine prepared from it can have no value in yellow fever prophylaxis and its use has been abandoned

Prof Hindle decided to apply methods of vaccination which have proved successful in the production of vaccines against such diseases as fowl plague, dog distemper, etc In June 1928 (*Brit Med Jour*, June 9, 1928) he showed that a phenol-glycerine emulsion of the liver and spleen of infected monkeys confers a very high degree of protection against very large amounts (10,000 to 100,000 lethal doses) of the virus A formalinised suspension shows the same vaccinating property During the past eighteen months these experiments have been extended and full details were given of the method of preparing this vaccine The earlier phenol glycerine vaccine has been replaced by a formalinised one, as the infection of glycerine is painful

The present method of preparing the vaccine is as follows The liver is removed from an infected monkey killed in the last stage of the disease, when the temperature begins to fall The organ is weighed and ground up in a mortar with fine sand A measured quantity of 9 per cent salt solution, equal to half the original weight of the tissue, is added and the mixture allowed to stand for a few hours Then distilled water is added equal to nine times the volume of the strong salt solution As a result, all the cells are cytolised liberating the contained virus, and one obtains a 20 per cent suspension of tissue extract in normal saline This suspension is allowed to sediment, then filtered through muslin Part of it is tested for virus content, and a 1 in 10,000 dilution of the original tissue should produce a fatal infection in a monkey

The virus suspension is killed by the addition of 1 to 2 per 1000 formaldehyde, and after twenty-four hours can be used as a vaccine, if it passes the usual sterility tests

Both phenol-glycerine and formalinised vaccines, when kept in the ice chest, have been found to preserve their properties for some months The first has also been dried *in vacuo*, after removing

the glycerine by dialysis, and found to retain its properties

Monkeys inoculated with these vaccines show a high degree of protection against yellow fever, and this protection has been tested against the inoculation of fresh virus and the bites of infected mosquitoes up to 4½ months after vaccination, without showing any signs of diminution In the majority of cases, about ten days after being vaccinated the monkeys were inoculated with 0 1 gm infected liver material, equivalent to 1000 to 10,000 lethal doses, and in some instances with very much greater quantities of virus

These results have been confirmed by Pettit and his collaborators working in Paris, and Aragão in Rio de Janeiro, who used a Brazilian strain of yellow fever Aragão obtained constant protection in monkeys, and therefore tested the vaccine in human beings, using a 20 per cent suspension of liver, spleen, brain, and kidney containing 2 per 1000 formaldehyde and 0 5 per cent phenol This vaccine was administered subcutaneously in 2 c c doses to the laboratory workers at the Institute Oswaldo Cruz, with no ill effects, and afterwards used in a small epidemic of yellow fever Between three hundred and four hundred people were vaccinated, including the health officers working in the infected neighbourhoods, and people living either in the same house or the vicinity of yellow fever cases Although no unwarranted conclusions were drawn, none of the vaccinated contracted the disease, although some of them must have been exposed to infection

The use of this modification of Hindle's vaccine has now been adopted by the Public Health Department of Brazil, and during the epidemic in Rio de Janeiro early in 1929 approximately 30,000 persons were vaccinated against yellow fever

In West Africa, there is urgent need for some additional method of protection against yellow fever, as evidenced by the number of past epidemics, for at present there seems to be no likelihood of anti mosquito campaigns succeeding in eradicating all chance of infection Accordingly, the British Colonial Office, and also the French and Belgian Governments, have decided to test this vaccine in their West African colonies

Prof Hindle is of opinion that, by the general use of a vaccine of this nature of proved efficiency in monkeys, there is every hope of yellow fever ceasing to be a source of danger in the world

Scientific Centenaries in 1930

THOUGH the year 1930 will not see the commemoration of any scientific centenary of such widespread interest as that of Faraday's discovery of electromagnetic induction, which will be celebrated in 1931, the year will recall a number of eminent men who have made notable contributions to many departments of science

The most famous name which appears among the centenaries for 1930 is that of Kepler, who died on Nov 15, 1630, at the age of fifty eight years Kepler forms a link between the sixteenth and seventeenth centuries Among those born in 1630 were the German chemist, Kunckel (1630–1703), who assisted in emancipating the literature of chemistry from the mysticism of alchemy, and Isaac Barrow (1630–1677), Gresham professor of geometry, first Lucasian professor at Cambridge and master of Trinity College, teacher and predecessor of Newton and one of the greatest religious scholars of his time Another name, also associated with Cambridge, is that of Thomas Plume (1630–1704), vicar of Greenwich and archdeacon of Rochester, whose preaching appealed to Pepys and Evelyn, and who, through reading Huygens' "Cosmotheoros", recommended to him by Flamsteed, left funds for erecting an observatory at Cambridge and for maintaining a professor of astronomy and experimental philosophy The first to become a Plumian professor was Roger Cotes, while the first observatory founded through Plume's generosity was over the King's Gate of Trinity College

The work of the eighteenth century is recalled by the names of Bezout (1730–1783), a mathematician of distinction, of Bochart de Saron (1730–1794), one of the first astronomers to suggest that Herschel's newly discovered body was a planet, and one of the French men of science who perished beneath the guillotine, of Messier (1730–1817), Louis XV's 'comet ferret', regarded at one time as the leading practical astronomer in France, and by that of Bossut (1730–1814), friend of Condorcet, D'Alembert, Bailly, and Lavoisier, a pioneer in the study of hydrodynamics and one whose work contributed to the improvement in the sailing qualities of the ships of the French Navy

Other scientific workers also born in 1730 include the English amateur astronomer, Aubert (1730–1805), the intimate of Smeaton, Banks, and Herschel, Josiah Wedgwood (1730–1795), the Boulton of the pottery industry, Ingenhousz (1730–1799), the Dutch physicist who spent the latter part of his life in England, and Duhamel (1730–1816), to whom France is indebted for improvements in steel making

Of men of science who died a hundred years ago, Fourier (1768–1830) was the most famous His "Théorie analytique de la chaleur" appeared in 1822, and it was Comte who predicted that when Fourier's doctrine was better known much use of it would be made in other branches of physics If Fourier recalls the golden age of French mathematics, the name of Cremona (1830–1903) brings to mind one who, last century, reorganised mathematical instruction throughout Italy His birth took place on Dec 7, 1830, and to 1830 also belong the names of H A Newton (1830–1896), both mathematician and astronomer, Carl Bruhns (1830–1881), friend of Encke and Galle, and director of the Leipzig Observatory, and the three eminent chemists, Raoult (1830–1901), recipient of the Davy Medal in 1892, Bemmelen (1830–1911),

who contributed to the founding of the Dutch school of physical chemistry, and Lothar Meyer (1830–1895), best known for the share he had in the periodic classification of the elements, and whose memorial lecture before the Chemical Society was delivered by Prof Bedson in 1896

The year 1830 also witnessed the death of Major James Rennel (1742–1830), the eminent geographer, who is buried in Westminster Abbey, of Richard Chenevix (1774–1830), the Irish chemist and mineralogist, whose name, like that of Rennel, is in the list of Copley medallists, and of Henry Bell (1767–1830), the steadfast but unfortunate promoter of steam navigation, whose *Comet* was the forerunner of the *Mauretania*, and it also saw the birth of David Edward Hughes (1830–1900), inventor and physicist, founder of famous scientific prizes and benefactor of the London hospitals, of Sir Edward Reed (1830–1906), the most prominent naval architect of his time, and of Gerhard von Rath (1830–1888), the Bonn mineralogist It also was marked by the founding of the Royal Geographical Society, while in January 1830, Lyell, then thirty two years of age, published the first part of his "Principles of Geology", that classic which Geikie said "must form an early part of the reading of every man who would wish to make himself an accomplished geologist"

News and Views

SUPPLEMENTING our article entitled "Pleistocene Man in China" in NATURE of Dec 28, 1929, p 973, we are informed that Prof Davidson Black has cabled from Peking (or, as the Chinese Government now calls the city, Peiping) on Dec 28 as follows "Recovered Chou Kou Tien uncrushed adult *Sinanthropus* skull entire except face letter follows" This presumably is a correction of the unofficial cable grams that appeared in the newspapers on Dec 15 and 16 mentioning "a complete skull with both the cranial and facial bones perfectly preserved" Prof Davidson Black's promised statement was made at a meeting of the Geological Society of China held on Dec 28 According to a message in the *Times* of Dec 30 from its Peking correspondent, the credit for the actual discovery lies with a young Chinese geologist, Mr W C Pei, who is in charge of the field work of the Geological Survey at Chou Kou Tien Some four tons of fossils have been excavated, including parts of two lower jaws, several teeth, and cranial fragments of man Among the mammalian remains is included the sabre toothed tiger, which is contemporary with Peking Man The evidence would appear to point to a very high antiquity indeed Dr Grabau, of the Chinese Geological Survey, is said to assign the skull to the beginning of the Quaternary Age, while that well known authority on Chinese geology and archæology, Père Teilhard de Chardin, gives it an estimated antiquity of 400,000 to 500,000 years If either of these estimates is confirmed, it would place this relic at comparatively little later than *Pithecanthropus* of Java The skull is at present embedded in hard travertine, but the right side and vault have been freed by the removal of a relatively softer part of the matrix It would appear that while the whole of the facial region is lacking, the brain case is almost complete and massive jaw sockets have been exposed The brow ridges are also said to be massive As compared with the Java skull, the length is approximately the same, but relatively there appears to be greater brain capacity

WE propose to publish week by week throughout this year a calendar of historic natural events, and the first set of notes in this series appears on pp 32, 33 It is intended to include in the weekly record as wide a range as possible of remarkable natural occurrences and phenomena observed in past times Great storms, floods, frosts, and similar meteorological phenomena will naturally make up a large part of the collected events, and notable earthquakes, volcanic eruptions, and like terrestrial disturbances will also frequently come into the calendar Whatever has commanded scientific attention on the earth or in the heavens—including of course the appearances of new stars, bright comets, and meteor showers—will, it is hoped, be brought back to memory under their appropriate dates during the year Events in the natural history or biological field are more difficult to assign to particular dates, and we shall be grateful to any readers of NATURE who will assist us with references or notes upon remarkable occurrences of this kind Without such aid it will be difficult to make the historic records so comprehensive as we should like them to be

THE material for the calendar will be derived from a great variety of sources, too numerous to mention individually Special reference should be made, however, to the *Quarterly Journal of the Royal Meteorological Society*, the *Meteorological Magazine*, Dr C Easton's work, "Les hivers dans l'Europe occidentale" (Leyden, 1928), W Andrew's "Famous Frosts and Frost Fairs in Great Britain" (London, 1887), and a manuscript collection of extracts from the Saxon Chronicle and Holinshed's Chronicles, compiled by the late Miss Eleanor A Ormerod and now in the possession of the Royal Meteorological Society In compiling the records, the dates employed have been those of the actual calendar in use at the time It will be recalled that, in 1752, eleven days were added to the date in the British Isles, Sept 2 being directly followed by Sept 14, in order to bring the calendar into conformity with that introduced by Pope Gregory XIII

IN the second week of this month the centenary of the discovery of the Murray River by Captain Charles Sturt will be commemorated by representatives of South Australia, New South Wales, and Victoria, who will meet at Wentworth on Jan 7 The next day the delegates will witness the opening of No 6 Lock, near the Victorian border, and during the following week they will proceed down the river, unveiling memorials at historic spots, arriving at Hindmarsh Island on

Jan 19 Here the Deputy Governor of South Australia will unveil a granite column 40 feet high, with a bronze tablet, to commemorate Capt Sturt's landing place after his journey in a whaleboat down the river a hundred years ago Sturt, who was born in 1795 and was educated at Harrow, served in the Peninsula and in France, and in 1827 became military secretary to Sir Ralph Darling, the Governor of New South Wales He made several hazardous journeys into the interior, and in 1829 descended the River Murrumbidgee to its confluence with the Murray, and by the latter travelled to the coast His discoveries led to the founding of South Australia, of which Captain (afterwards Rear Admiral Sir John) Hindmarsh became the first Governor in 1836 Sturt afterwards became the assistant commissioner of lands and colonial secretary of the new colony, and one of the counties bordered by the Murray River bears his name He published accounts of his journeys and received the founder's gold medal of the Royal Geographical Society Sturt returned to England in 1853 and died at Cheltenham on June 16, 1869

THE Report on the Administration of the Meteorological Department of the Government of India in 1928–29 has recently been issued It covers the period during which the head office was reorganised and moved from Simla to commodious new buildings at Poona The opening ceremony which took place on July 20, 1928, is described in this report, and the speeches made on that occasion give a good conspectus of the present position and future prospects of the department The men who occupy the superintendentships of the various branches at headquarters are all Indians It is to them and their younger colleagues that we must chiefly look for new contributions to our meteorological knowledge of India during the next decade or so, and it is perhaps a good augury that the dislocation caused by the move has not prevented research work from being carried out during the period under review Some of those researches have already been reviewed in our columns

SIMLA was badly placed for three very important pieces of work Mr J H Field, the late Director General of the Department, had to conduct his pioneer work in the exploration of the upper atmosphere, by means of sounding balloons carrying self recording instruments, far from the central office, for balloons liberated at Simla are generally lost outright in remote parts of the Himalayas or in Tibet, carried eastwards in the circumpolar westerly circulation that is in evidence at high levels in northern India throughout a large part of the year An equally important line of investigation—the study of the tropical cyclones of the Arabian Sea—is also more readily conducted with Poona as a base Lastly, there is the forecasting of the monsoon, upon which the economic life of India is so dependent The rain bearing south westerlies from the far side of the equator reach Poona early, and in full strength, while Simla not only experiences them long after the greater part of India, but also as a 'wave' that has nearly spent its poleward impulse

THE Safety in Mines Research Board has come to the conclusion that its technical papers are somewhat too difficult for the ordinary miner to understand, and it has, therefore, commenced to issue a series of pamphlets headed "What Every Mining Man Should Know" The first two of these have now been published, and are priced at a very low sum (6*d* and 3*d* respectively) in order to make them generally available The first deals with research problems that have already been more or less completely solved and those that are now undergoing investigation, the object apparently being to bring before the ordinary coal miner the large volume of data which are as yet unknown and will have to be found out before coal mining can be made as safe as is humanly possible The second pamphlet is on gas and flame, and attempts to make clear to the unscientifically trained mind the rationale of gas ignition and gas explosion The authors have attempted to attain this object by photographs of a number of experiments, no doubt if the experiments could actually be seen, they would make the matter quite clear to the uninitiated, but it cannot be said that the photographs alone are equally conclusive Upon the whole, the effort, and especially the objects underlying it, are praiseworthy, unfortunately, it may be gravely doubted whether the great body of coal miners will be sufficiently interested even to read these pamphlets

DURING recent years there has grown up a general recognition of the value of international conferences This is especially evident in connexion with illumination, a subject which is in a state of constant development International co operation has been greatly fostered by the reconstitution of the original International Photometric Commission, on a wider basis, as the International Illumination Commission to which are linked national committees in all the chief countries of the world Since the War, meetings held in Paris (1921), Geneva (1924), Bellagio (1927), and New York (1928) have revealed continuous progress The conference held in the United States last year, which was attended by five hundred delegates from eleven different countries, was perhaps the most important ever held in connexion with illumination The next International Illumination Congress will be held in Great Britain on Sept 3–13, 1931, and will be combined with excursions to places of interest in England and Scotland Papers dealing with varied aspects of lighting will be presented, and topics of local interest will be dealt with at each centre The congress will be followed by the technical meetings of the International Commission on Illumination, which will be held in Cambridge on Sept 13–19 In Great Britain the machinery for the study of illumination is perhaps more perfectly organised than elsewhere, and the aid of all the leading scientific and technical bodies interested, and of organisations concerned with gas and electric lighting, is being secured The honorary general secretary of the Congress is Col C H Silvester Evans (c/o The Illuminating Engineering Society, 32 Victoria Street, London, S W 1), to whom all communications should be addressed

MR T G N HALDANE read a remarkable paper to the Institution of Electrical Engineers on Dec 19 He described a new method of producing low grade

heat from electricity by means of a device which he calls a heat pump In 1824, Carnot imagined a perfect reversible heat engine and proved that its efficiency is the ratio of the difference of temperature between the high and low temperatures of the working substance to the high temperature when the temperatures are expressed in the absolute scale If we imagine the Carnot engine reversed, that is, if it be supplied with mechanical energy, then a small amount of mechanical energy will allow a very much larger amount of heat to be pumped from the low source to the high source The general principle of this process was first pointed out by Kelvin in 1852 Little practical application has been made of it hitherto, possibly because it appears at first sight to contradict ordinary engineering principles Mr Haldane points out that the process of producing cold is simply that of pumping heat from a relatively cold to a relatively hot source Hence the refrigerator is the most familiar type of heat pump It is shown both from theoretical considerations and from practical tests on refrigerating plant that where heat at a comparatively low temperature is required, an 'efficiency' of the order of from 300 to 500 per cent can be obtained The heating efficiency is the ratio of the heat produced by the heat pump to the heat equivalent of the electrical energy expended The principle can be applied to the heating of large buildings and very usefully to the heating of public baths A description is given of experiments which demonstrate the soundness of the principles used Engineering estimates are given It appears that the heating of swimming baths is the most suitable field for the immediate application of the system

USERS of the telephone will find a paper, on interruptions on telephone conversations, by Mr K W Waterson, published in the *Bell Telephone Quarterly* (vol 7, p 166), both interesting and useful Every one has felt annoyance when a telephone conversation is suddenly interrupted by what is technically called a 'cutoff' It is small consolation to know that this only occurs about six times in a thousand Half of these are due to failure in human effort by the operators or to a fault in the extensive network connecting the two subscribers The other half are in private switchboards which are outside the company's control 'Cutoffs' on conversations from dial telephones occur less frequently than on connexions completed manually, as there is less opportunity for human error All long distance calls are subject to a greater risk of a cutoff In a long distance cable connexion from New York to Chicago there are 1500 relay or movable contacts and 9000 other fixed contacts of various kinds In addition, there are 40,000 soldered connexions in the toll line itself Considering the complication of handling the calls on a switchboard, the operator does well to keep his mistakes down to 1 in 1500, which is less than one in a day's work

THE errors due to the telephone subscriber generally arise when he trusts too much to his memory when calling a number, when he speaks indistinctly, or when, in the case of a dial telephone, he dials before hearing the dial tone During the last ten years the percentage of wrong numbers asked for by the subscribers has remained practically constant On the other hand, the wrong numbers attributable to the telephone company have diminished to half their former value At present it is difficult to see how the causes of 'bell rang' complaints can ever be eliminated However good the maintenance of the apparatus, it will occasionally get out of order, and however excellent the training and supervision, operators will sometimes err It is not always convenient for a subscriber to carry on a conversation the moment he is called, and the caller is often not able to wait until he gets a reply All efforts should be made to effect improvements in this direction

THE lure of spectroscopic investigation as applied to industry fascinates many a chemist until he reads a treatise, studies the subject in detail, and concludes that the goal is beyond his reach owing to high cost of equipment and the need for long training in the technique However far from or near to the truth this may be in the ordinary way, the reader will find his fears greatly reduced or even dispelled in a new publication entitled "Spectroscopic Outfits for Metallurgical Analysis" (4to, pp 40), published by Messrs Adam Hilger, Ltd Equipments of various types are so clearly described with regard to both their construction and the purposes to which they are adaptable, that the reader can scarcely fail to make a wise selection and to be assured that the cost will not greatly exceed the sum estimated, since accessories are listed together with the main equipment Part 2 opens up three new methods of quantitative spectrographic analysis, Barratt's twin spark photometric method, in which the unknown intensity of the given lines is adjusted to equality with that of known lines, Scheibe and Neuhäusser's method employing a 'rotating logarithmic wedge sector', which expresses in the length of the photographed line a function of its intensity, and Occhialini's method, also depending on measurements of the lengths of lines

SINCE the Arctic Islands of Canada were incorporated in the North West Territories of the Dominion, a great deal of exploration and survey work have been done annually, both in respect of routine patrols and in definitive pieces of investigation A small chart, published by the National Resources Intelligence Branch of the Department of the Interior, shows the routes of officers carrying out patrols, inspection, and investigation during the present year, by land and by sea Nearly the whole of the north west passage was visited, and extensive explorations were made in the little known Foxe peninsula, the eastern side of Foxe basin, and the northern coasts of Hudson Strait Most of the coasts of Baffin Island were visited, and in the far north patrols touched Melville Island, Bathurst Island, and Alex Heiberg Island, besides Ellesmere Island, where there is a police post The Department keeps in active touch with all the areas inhabited by Eskimo, and has made Canadian jurisdiction much more than nominal in these arctic territories

ON Dec 23, according to the *Times*, a memorial to Sir Stamford Raffles was unveiled in Batavia Born at sea, off Jamaica, in July 1781, Raffles at the age of

fourteen entered the East India house and in 1805 was sent to the Far East as assistant secretary of Penang Rising rapidly to more responsible positions, from 1811 until 1816 he was Lieutenant Governor of Java, where he abolished slavery, instituted schools, and in other ways ameliorated the lot of the natives His work, it was said, "will make his memory adored on the island of Java for ages to come" Afterwards Governor of Bencoolen in Sumatra, in 1819 he hoisted the British flag in Singapore He returned to England in 1824, where he founded the Zoological Society of which he was the first president His death occurred on July 5, 1826, and his statue was afterwards placed in the north aisle of the choir of Westminster Abbey

IN his address at the twelfth anniversary meeting of the Bose Institute, Sir J C Bose said that the advance of plant physiology had been obstructed by narrow specialisation His new type of 'growth balance' not only visualises imperceptible growth but makes an immediate measurement of the rate The establishment of the laws of growth, on which the advance of scientific agriculture depends, has been rendered possible by this new method Experiments carried out side by side on plant and animal tissue have established identical life mechanism in the two kingdoms The leg of the frog and the leaf of Mimosa produce similar motile response under nervous impulse caused by cathodic excitation of an electric current The characteristic effects of drugs are shown in automatic pulsations of both plant and animal Indian plants are being found having medicinal properties which were not previously suspected, and the efficacy of which in reviving the failing heart appears to be exceptionally high Further steps necessitate the isolation of the active principles from plant extracts as well as prolonged investigation for standardisation of dose on human subjects

IN the November *Scientific Monthly*, Prof M F Guyer describes the marine biological stations of Japan So much good work has come out of these institutions that it is interesting to have some general account of them, and the attractive photographs inspire one with a desire to work in these laboratories Two are described, the Marine Biological Station at Asamushi on the north eastern coast of the main Island of Japan, and the Misaki Marine Biological Station, which lies on the southern extremity of a peninsula which separates the Bay of Tokyo from Sagami Sea Both offer hospitality to foreign workers and both have much to offer in interesting plants and animals and ideal collecting grounds The Asamushi Station has a staff of fourteen, with Prof Hatai as director There is a well equipped laboratory and aquarium and an under sea laboratory which is half submerged The Misaki Station was founded by the Japanese Government in 1887 at the suggestion of Prof Mitsukuri It is now under the direction of Prof Yatsu of the Tokyo Imperial University The wonderful fauna and flora of this part of the world is well known for its richness, and regular courses are given for teachers in fisheries, planktology, and oceanography Here also the laboratory is well equipped, and there is a library and aquarium, besides research rooms for investigators Both of these stations are of the greatest possible value

THE question of growing crops subsidiary to the staple products of a country is discussed in a recent issue of the *Bulletin of the Imperial Institute*, vol 27 p 307, with particular reference to the tropical colonies The danger of depending solely on one crop has recently been emphasised by the occurrence of a slump in the tobacco industry in Rhodesia, Nyasaland, and elsewhere, but many factors notably transport, need to be considered before a suitable subsidiary export crop is selected The industry suggested is the manufacture of essential oils, of which peppermint, geranium, and lavender appear the most promising The oil is prepared from the plants by steam distillation, the process being carried out by the grower on the spot A full account of the different varieties the methods of cultivation, harvesting, and preparation of the oil, is given for each plant, together with the average yields to be expected and the present market conditions Co operation with the Royal Botanic Gardens at Kew is being arranged plants for trial cultivation being sent to certain areas and the resulting oil being returned to the Imperial Institute for analysis and valuation For those desiring further information a list of useful references is appended, the Imperial Institute is prepared to advise planters with regard to the type of still required and to put them into touch with makers of the necessary apparatus and merchants through whom the oils may be marketed Intending planters are, however, also recommended to consult the agricultural officers of the country concerned so that they may obtain advice based on a thorough knowledge of local conditions

THE growing appreciation of the value of trade associations for protecting the interests of their members is exemplified by the formation of the British Disinfectant Manufacturers' Association, the inaugural meeting of which was held on Dec 16 last About fifty firms, representative of all the branches of the disinfectant trade, have signified their intention of joining the new Association One of the main objects of the Association is to protect and further the mutual trade interests of its members, to foster the manufacture of British disinfectants and promote closer co operation between British disinfectant manufacturers The Association will also serve as a medium for placing before government departments or other public bodies, at home and abroad, the views of British disinfectant manufacturers on matters affecting their industry Mr N F Kingzett, of the Sanitas Co, Ltd, was elected chairman, Mr W H Hivey, of Taylor's Automatic Disinfector, Ltd vice chairman and Mr R A Blair of Burt, Boulton, and Haywood Ltd, honorary treasurer of the new Association, which will be affiliated to the Association of British Chemical Manufacturers, 166 Piccadilly W 1 The Association has already taken steps to investigate certain questions of tests which have arisen in connexion with the standardisation of disinfectant specifications by a government committee

We much regret to announce the death, on Dec 25, of Major P A MacMahon, F R S, president in 1917–19 of the Royal Astronomical Society, who was formerly Deputy Warden of Standards, Board of Trade, at the age of seventy five years, also of Major P H Hepburn, president in 1920–22 of the British Astronomical Association and treasurer in 1927–28 of the Royal Astronomical Society, on Dec 25, aged fifty six years

The fourteenth series of "Methods and Problems of Medical Education" has been issued by the Rockefeller Foundation, New York Methods of keeping records are dealt with in this series, and as models specimens of the following are given (1) the complete case sheets of a case of fracture, Massachusetts General Hospital, (2) the blank forms used in a sanitary survey, Peking Union Medical College, and (3) a summary of the records and record system of the Children's Hospital, Cincinnati, Ohio

Applications are invited for the following appointments, on or before the dates mentioned —A principal of the County Technical College and School of Art, and organiser of evening school work in the Borough of Newark—The Clerk to the Governors, Education Offices, Old Magnus Buildings, Newark (Jan 14) A principal of the County Technical Institute, Worksop—The Director of Education, Shire Hall, Nottingham (Jan 25) A lecturer in physical and stratigraphical geology in the Egyptian University, Faculty of Science, Cairo—The Dean of the Faculty of Science, Egyptian University, Cairo (Jan 31)

Our Astronomical Column

An Active Region on the Sun —Although the maximum of the present cycle was reached in 1928, the sun has shown considerable activity during the past three months in the appearance of several large spots (see Nature, Oct 19, p 631, Nov 9, p 737, Dec 7, p 888, Dec 28, p 998) During the latter part of December, another group of spots crossed the disc, covering with its attendant faculæ a great extent of the sun's surface The group (or possibly two separate but allied groups), which consisted of a long stream extending over 18° of longitude or 130,000 miles, occupied the place of the big naked eye spot, No 16 of the previous rotation, which also was the return of a complex stream beginning its development on Oct 30 Notes relating to the early history of this active region are given in the *Observatory* for December last, p 365

The present group was observed at Greenwich with the spectrohelioscope presented to the Royal Observatory by Dr Hale, and it was seen to be associated with extensive bright hydrogen flocculi Preceding the group, on Dec 24–26 (the only days when observation was possible), there was a very long, slender, dark filament which represented a prominence of considerable size and activity Measures taken with the velocity recorder or 'line shifter' of the spectrohelioscope showed on Dec 25 a difference of 95 km / sec in radial velocity between the two ends of the filament, the southern end rising from the sun with a velocity of 25 km /sec and the northern end falling back with a velocity of 70 km /sec A detailed account of a similar observation of a dark filament but connected directly with a sunspot is given by Dr Hale in Nature of May 14, 1927, p 711

The following table completes the list of large sun spots seen during the year 1929

No	Date on Disc	Central Meridian Passage	Latitude	Maximum Area
19	Dec 21–Jan 2	Dec 27 5	16° N	2000

Comets —A new comet, 1929*d*, was discovered on Dec 20 by Mr Wilk of Cracow Observatory, who will be remembered as one of the discoverers of comet 1925XI (Peltier Wilk) The following positions, of which the first is only approximate, have been transmitted by telegram from the I A U Bureau, Copenhagen

U T	R A 1929 0	N Decl 1929 0	Observer	Place
Dec 20d 17h 45m	18h 8m 35s	36° 19	Wilk	Cracow
21 17 32 1	18 20 15 67	35 23 30	Wolf	Königstuhl

The magnitude was noted as 7 on Dec 20, 9 on Dec 21 The deduced rate of daily motion is $+11^m\ 48^s$, $-56'$ This gives the rough position for the evening of Dec 28, R A $19^h\ 43^m$, N Decl 28° 52′, which is some 5° east of β Cygni This is the first comet readily visible with small instruments in European latitudes for nearly two years, and the first orbit likely to prove parabolic since the bright comet 1927IX (Skjellerup)

As the comet is approaching the sun, though receding from the earth, it is likely to become somewhat brighter the following positions were secured by Dr W H Steavenson at Norwood

		R A 1929 0	N Decl 1929 0
Dec 25	18 37 3 U T	19h 5m 36 64s	30° 42′ 14″
„ 26	18 21 0 „	19 15 47 91	29 24 37

Prof Banachiewicz, Director of Cracow Observatory, has deduced the following orbit from observations on Dec 21, 23, 25

$$\begin{array}{ll} T & 1930 \text{ Jan } 22\,257 \\ \omega & \left.\begin{array}{l} 157^\circ\ 8' \\ 178\ \ 41 \\ 124\ \ 31 \end{array}\right\} 1929\,0 \\ \Omega & \\ i & \\ \log q & 9\,82840 \end{array}$$

Ephemeris for 18h U T

	R A	N Decl	log r	log Δ
Jan 1	20h 9m 50s	21° 1′	9 9006	9 9789
„ 5	20 38 1	15 24	9 8783	0 0054
„ 9	21 1 4	10 8	9 8586	0 0359
„ 13	21 19 45	5 18	9 8430	0 0679
„ 17	21 34 51	1 3	9 8328	0 0990

An observation by Dr A C D Crommelin on Dec 29, not yet fully reduced, shows that the position was within 1′ or 2′ of the ephemeris place, so that the elements are probably near the truth the comet must be looked for in the evening as soon as the sky is dark enough

Prof van Biesbroeck followed Forbes's Comet, 1929*c*, at Yerkes Observatory until Nov 22 on Nov 5 it was of mag 15, with a diffused nucleus and a tail on the following side On Nov 22 the magnitude was 16 5 He is still following Stearns's Comet, 1927IV, with the 24 inch reflector Its magnitude is 16 Carpenter's reported comet of Nov 2 may be written off as unconfirmed

Research Items

The Earliest Civilisation of Egypt.—In *Antiquity* for December, Mr. Guy Brunton gives a brief account of the progress of excavation at Badari since it was initiated in 1922. He sketches in outline the civilisation of the Badarians so far as it can be reconstructed from the evidence, dating it approximately at 5000 B.C., going on to describe the differing and, it is suggested, earlier culture of the Tasians, discovered in the expeditions of the last two years. Certain points differentiate them sharply from the Badarians. The typical form of pottery is a jar having a small flat base, wide mouth, and a rather sharp angle at the bulge. The ware is greyish with black patches, and shows a vague coarse rippling which is vertical. There is sometimes a definite irregular black band around the rim. Associated with these people are beaker pots with broad flaring mouths and incised designs filled with white. Two more or less whole and many fragments come from the village sites, none so far from graves. In five places they have been found with polished celts, either of hard limestone or greyish green igneous rock. The Tasians are definitely connected with the celts by an undisturbed grave at Deir Tasa, in which was typical Tasian pottery. A poor example of the beaker was found in a Badarian grave at Qau in 1923, and may indicate an overlap of the two cultures. The Tasian culture is more primitive than the Badarian, and everything points to its being earlier. A few skulls have been found in good condition. They are rounder than the pro-dynastic or the Badarian, and have broad faces and square jaws quite unlike the Badarian. The graves are wider and deeper than the Badarian, with a niche in the side to take the pot.

Change in an African Society.—In the *Sudan Notes and Records*, vol. 12, Part 1, Mr. G. O. Whitehead publishes a study of the social organisation of the Bari, with special reference to the changes which have taken place comparatively recently in the status of the various social groups. The Bari were formerly composed of freemen, *Lui*, and servile groups, collectively called *Dupi*. The *Dupi* proper were serfs who cooked, and were of a physique markedly distinct from their masters. They did not own cattle, but are supposed to have lost them to the freemen. Yet they had to pay cattle on marriage, these being obtained from their masters. For this the masters had a claim on their services. Probably they were racially distinct from the freemen who had conquered them when they invaded the land. Other classes were the hunters, neither owning cattle nor cultivating land. They paid tribute to their chief. Two other classes were the Artisans of the Forge and the Artisans of the River, each living in separate villages. They were not so servile as the *Dupi*. They had few or no cattle, yet married independently of their chief's assistance owing to the value of the goods they produced. The introduction of money, the increase in agriculture, and disturbance due to unrest in the Sudan have brought about a redistribution in the ownership of cattle, which no longer belong exclusively to the *Lui*, and a dislocation of the pastoral life. This has blurred the hard and fast lines between the classes. The *Dupi* no longer depend on the *Lui* for their marriage arrangements, while under European control the position of the chief is changed and depends upon the relation with the Government rather than his own intrinsic position. The advice of the fathers of the soil is no longer listened to as it once was.

Yellow Fever Vaccine.—Stokes, Bauer, and Hudson in 1927 made the important discovery that Asiatic monkeys, particularly *Macacus rhesus*, can be readily infected with yellow fever, and that the disease may be maintained in these animals either by direct inoculation of infected blood or tissues, or by mosquito transmission. By this means, Hindle has been able to maintain and propagate the virus in London for more than a year, and through a large series of animals (*Trans. Roy. Soc. Trop. Med. and Hyg.*, 22, p. 405, 1929). Hindle finds that a suspension of the ground and cytolised liver and spleen taken from an animal *in extremis* will produce infection in a dilution of 1 : 10,000, but if to the suspension two parts of formaldehyde per thousand are added and the mixture is kept in the ice chest for twenty-four hours, virulence is lost and the material may be used as a preventive vaccine. A monkey inoculated about ten days previously with this vaccine resists a dose of 1000-10,000 minimal lethal doses of active virus, and the immunity produced lasts for more than six months, the longest period so far tested.

Snakes of Ceylon.—A useful paper, by L. Nicholls, deals with the simpler recognition marks of the land snakes of Ceylon (*Ceylon Jour. Sci.*, Sect. D, vol. 2, Pt. 3, 1929, p. 91). Since every year deaths in Ceylon are attributed to non-poisonous snakes, the diagnoses have been arranged so that medical men may have at hand a ready means of determining any species and its possible harmfulness to man. In all, 61 species are described, 14 of which are earth snakes, 1 a constrictor, 42 colubrids, and 4 vipers. So far as possible, technically difficult descriptions have been avoided and identification rests for the most part on the external characters of coloration, markings, and general appearance, and simple scale characters.

Teleostean Fishes of Tortugas.—Mr. E. W. Gudger ("On the Morphology, Coloration, and Behaviour of Seventy Teleostean Fishes of Tortugas, Florida." Papers of the Tortugas Laboratory of the Carnegie Institution of Washington, vol. 26, No. 5) gives an account of his observations on various fishes. The work is specially valuable as it has to do mainly with living material, giving details of the colouring, variation, and habits both in natural surroundings and in the aquarium. Special stress is laid on the importance of the variability in colouring. The fishes also vary much in number of fin rays, scales, and relative proportions of the body. The small clupeoid *Jenkinsia stolifera* is present in schools of many thousands, often swarming round a large grey snapper, leaving a space round it and moving when it moves, only to rearrange themselves in the same way when it comes to rest. The account of the feeding habits of the grey snapper itself is interesting. *Apogonichthys puncticulatus* was found swimming inside the mouth of the shell of a large conch (*Strombus bituberculatus*), and probably lives symbiotically with this mollusk, in the same way in which *Apogonichthys strombi* lives in *Strombus gigas* as described by Plate from the Bahamas. Anatomical details of many of the fishes are given, including many notes on the internal organs besides the external features.

Gonophores of *Myriothela*.—E. A. Briggs (*Records Austr. Mus.*, vol. 18, 1929) describes the gonophores of *Myriothela australis*. All the gonophores on one individual are of the same sex; they are spherical when mature, supported on narrow cylindrical peduncles

arising from the sides of the blastostyles The male cells are derived from cells on the floor of the sub umbrellar cavity, and the first stage in spermato genesis begins in the mass of cells covering the spadix The secondary spermatocytes derived therefrom fill the subumbrellar cavity At the distal pole of the gonophore, the ectoderm becomes invaginated to form the velar aperture, which breaks through into the subumbrellar cavity, and permits the escape of the sperms In the female gonophore the cells of the germinal mass are arranged in several layers, the outer of which forms the external epithelium of the future spadix, and the others are the reproductive cells and form the oogonia These multiply and finally fill the space between the manubrium and the subumbrellar epithelium The oogonia give rise to primary oocytes, and here and there two of these come into contact and their cytoplasm fuses The fusion products in crease by accretion of other similar ones or of primary oocytes The end result is that in the gonophore are five or six plasmodial masses separated by non cellular partitions The large definitive egg is pro duced by the withdrawal of these partitions and the fusion of the plasmodia, and becomes charged with yolk At the distal pole of the gonophore is the velar aperture through which probably the sperm enters

***Cardita beaumonti* Beds of Sind** —The *Cardita* [or *Venericardia*] *beaumonti* beds as they occur in Balu chistan were treated of by M Henri Douvillé in a previous paper (see NATURE, Oct 6, 1928, p 552), and he now deals with them as developed in Sind (*Pal Ind*, New Series, vol 10, mem 3, fasc 2) The fauna of these beds in Sind is definitely marine, as evinced by the abundance of Nautili and Fusidæ, whereas in Baluchistan more brackish water forms, and particularly Melaniidæ, prevail Stratigraphical evidence shows that in Baluchistan the beds represent the lower Danian, whilst in Sind they are at the top and underlie the basaltic trap of the Lakhi hills Many of the Sind species differ solely in specific characters from Eocene forms Just fifty species of mollusca are described, half of which are held to be new and illustrated on eleven photolitho plates, which, considering the nature of the objects depicted, are remarkably good

Petrographic Nomenclature —In the *Travaux du Musée Minéralogique près l'Académie des Sciences de l'U R S S*, vol 3, 1929, Dr Belliankin gives an inter esting discussion (in English) of the meaning of the term 'rock' He arrives at the definition 'Rock is a mineral body, homogeneous in matter and struc ture", where 'mineral body' includes aggregates of one or more minerals, mineral mixtures or glasses From this it is deduced that the classification and nomenclature of rocks should be primarily minera logical Belliankin points out that geographical names are not suitable, and that "a text book of petro graphy turns out to be a certain kind of universal manual of geography" As a concrete suggestion for a practicable alternative, he proposes to name rocks from the first syllables of the names of their dominant minerals For felspathoidal rocks he thus arrives at the following names, based on the abbreviations italicised in *ægi*rine, *py*roxene, *di*opside, *titan py* roxene, *am*phibole, *bar*kevikite, *bi*otite, *ne*pheline, *so*dalite, *no*sean, *ana*lcite, *meli*lite

Geographical Names	*Rational Names*
Urtite	Leuco ægineite
Ijolite	Ægineite
Melteigite	Melano ægineite
Monmouthite	Amnite
Congressite	Bineite
Tawite	Ægisodite
Naujaite	Anam ægisodite
Bekinkinite	Barneite
Fasinite	Tipyneite
Riedenite	Pynosite
Turjaite	Binemelite
Uncompahgrite	Dimelite

The suggestion is an excellent one, it deserves serious discussion at the next International Congress of Geology

Wave-Mechanics of α-Ray Tracks —In a note in the December number of the *Proceedings of the Royal Society*, Mr N F Mott discusses the apparent con tradiction between the wave mechanical theory of radioactive disintegration, according to which an α particle leaks out from its parent nucleus as a spherical wave, and its particle like attribute of leaving an almost linear trail in a Wilson cloud chamber The discrepancy is, of course, only appar ent The wave of the α particle must not be con sidered by itself, but as contributing to a wave-function in a space of many dimensions formed by the co ordinates both of the α particle and of every atom in the expansion chamber Mr Mott develops the appropriate theory for the case when there are two atoms of hydrogen present, and finds that both must lie within a cone of small angle having its apex at the radioactive nucleus, if they are both to be ionised In other words, the α particle should, apart from collisions with atomic nuclei, leave an almost straight trail Mr Mott's paper is an elaboration of one of the points raised by Prof C G Darwin in his paper on collision problems in wave mechanics in the June issue of the *Proceedings*

Measurement of Refractive Indices —A rapid method for investigating the dispersion of liquids is described by Prof T M Lowry and Mr C B Allsopp in the December number of the *Proceedings of the Royal Society* A small quantity of the substance is enclosed in a quartz etalon, and the interference fringes formed in the film in parallel light are focused on to the slit of a spectrometer, when the variation in fringe width in passing along the spectrum—photographed in the usual way—leads readily to a knowledge of the dispersion in the liquid The accu racy obtainable is not so high as in some methods, being largely limited by the number of fringes which can be thrown on to the slit, but the device of working with thin films in quartz makes it possible to follow the dispersion curve of even poorly transmitting substances well into the ultra violet, and the informa tion so obtained is very complete A curve for nicotene, which was obtained without very elaborate precautions in the control of temperature, is repro duced in the paper, and extends to 2900 A hollow prism methods could only be used down to about 4300 A, below which it was impracticable to proceed, because of absorption in the liquid

Photoelasticity —In the first part of volume 12 of the *Scientific Papers* of the Institute of Physical and Chemical Research, Tokyo, Mr Z Tuzi describes a new method of studying the elastic stresses in struc tures by means of the kinematograph A model in phenolite is placed between crossed nicol prisms through which monochromatic green light is sent The light and dark bands produced by the stressed specimen are photographed either in the usual way with a steady load or on a kinematograph film during the application of the load Photographs of the bands produced when the steel side of a railway carriage with its doors and windows is loaded at nine points on its top edge, are reproduced for a steady load and

for its gradual application, and are remarkably clear The stresses are calculated from the photographs and are compared with the values calculated by the approximate methods used in designing the carriage The agreement is not satisfactory, and the author gives more accurate methods of calculation which agree better with the experimental results

Shearing and Punching Metals—More than 110 pages of the *Bulletin* of the Société d Encouragement pour l'Industrie Nationale for July August September are devoted to M Charles Fremont's account of his researches on the shearing and punching of metals, which have been carried out with the support of the Society He has investigated the influence of the form of the shears or punch on the work which has to be done in the shearing or punching process, and by means of photomicrographs determined the distortion the material undergoes The 268 figures add greatly to the interest of the memoir

Precipitated Selenium Dioxide—In the November issue of the *Journal of the American Chemical Society*, Hoffmann and Lenher show that the precipitate formed by the action of ozonised oxygen on a solution of selenium in selenium oxychloride is selenium dioxide The density of the precipitated dioxide is appreciably lower than that of the sublimed substance, although the molecular weights of the two were found to be identical The precipitated dioxide absorbs dry hydrogen chloride to form a fuming, straw coloured liquid similar in composition and density to selenium hydroxychloride No evidence of the existence of selenium trioxide or chloroselenic acid was found

Union of Hydrogen and Chlorine—When a mixture of equal volumes of hydrogen and chlorine is exposed to white light of constant intensity, combination occurs more slowly in narrow capillary tubes than in wider D L Chapman and Grigg, who discovered this effect, explained it by assuming that the combination is due to an unstable catalyst which is destroyed in contact with glass or a film of water In the November number of the *Journal of the Chemical Society*, they describe further experiments which show that the mean life of the catalyst is of the order of magnitude of the time taken by the catalyst molecules to reach the surface, although there are some points in which the theory proposed is not closely followed The mean life always increases with decreasing pressure, which seems to show that one or both of the reacting gases have an inhibitive effect, a conclusion which is supported by an observation of M C C Chapman that hydrogen can act as a weak inhibitor The results are consistent with those of Weigert and Kellermann, published in 1923, these authors being the first to attempt to estimate the life of the catalyst which is formed when the gas is exposed to light The experiments give no indication as to whether this catalyst is a chain of alternately formed chlorine and hydrogen atoms, as postulated by Nernst and Bodenstein, or unstable nuclei of unknown structure

Glycogen—Glycogen is a peculiar material very similar to starch which is found in the livers of mammalia It is coloured wine red by iodine In the November number of the *Journal of the Chemical Society*, Haworth, Hirst, and Webb describe some preliminary experiments with glycogen which indicate that the hypothesis supported by Karrer, that starch and glycogen are similarly constituted, both structurally and configurationally, is correct. The difference in the colour reaction with iodine may be distinctive, but it is possible to prepare a starch fraction which gives the same colour as glycogen In accordance with modern views, glycogen is assumed to be constituted on the basis of continuous maltose units, that is, of a conjugated chain of a glucose units The difference in properties of the two substances is supposed to be due to a difference in size of their respective micelles The experiments involved acetylation of glycogen with acetic anhydride, in presence of either chlorine or sulphur chloride as catalysts or of pyridine, when the triacetate was obtained in almost quantitative yield as a white powder Although this was denser than starch triacetate the two products showed nearly the same optical rotation in chloroform solution Deacetylation gave a regenerated glycogen having all the characteristic properties of the original polysaccharide Similar results were obtained by methylation following simultaneous deacetylation of the two triacetates

Experimental Cold-rolling Mill—The invention of rolls for metal working dates back at least so far as the twelfth century, probably being used then for producing gold strip Leonardo da Vinci was the first to suggest their use for heavier work, but the rolling of iron did not come in until the eighteenth century The Swedish man of science and engineer Triewald had a rolling mill with 10 inch rolls, but it was in England that the mill was fully developed and rolling both hot and cold is widespread To further the study of the cold rolling of steel and other metals a cold rolling mill has been placed in a new laboratory attached to the metallurgical and engineering departments of the University of Sheffield, (see NATURE July 13 p 66) The machine, constructed by Messrs W H A Robertson and Co, Ltd, of Bedford is described in *Engineering* for Dec 6 The rolls of Hadura alloy steel made and presented by Messrs Hadfields, Ltd, are 10 in diameter by 10 in face and are suitable for the cold rolling of strip up to 6 or 7 inches wide Special attention has been given to the cooling of the rolls and the lubrication of the bearings, and the rolls are driven by an electric motor of 50 120 h p, giving a speed of anything from 59 3 ft to 300 ft per minute A good deal of the work done will naturally be in the direction of metallurgical research, but it is hoped that opportunity will be taken to obtain reliable data on the effect of rolling speed on power consumption, accuracy, etc, matters of the greatest value to the industry

Fuel Tests—Canada's resources in fuel are abundant, but the distribution is unfortunate Ontario and Quebec rely largely on anthracite from the United States This dependence has been inconvenient in recent years owing to recurrent shortages, and many substitutes have been tried In order to determine the relative value of these, the Dominion Department of Mines has instituted a series of "Comparative tests of various fuels when burned in a domestic hot water boiler", reported by E S Malloch and C E Baltzer (*Report* No 705 Ottawa F A Acland, 1929, 20 cents) These tests were carried out with great elaboration and on thirty fuels of the most varied type, ranging from anthracite to peat, consumed in a typical domestic appliance and for house heating The most efficient fuel tested was Welsh anthracite, 8 4 tons of which was equal to 10 tons of American anthracite, taken as standard Scotch semi anthracite was nearly as good The tests showed that more than 70 per cent of the heat of anthracites and cokes could be transferred to the water With semi bituminous coals 65 per cent, and with low grade fuel less than 55 per cent, of the heating value of the fuel could be utilised The results should be very encouraging to those interested in the export of British coals

Nickel Steel in the *Golden Arrow.*

THE publications of the Bureau of Information on Nickel of the Mond Nickel Co, Ltd, have from time to time provided most valuable information on many different aspects of the use of nickel in all types of metallurgical and engineering activity Paper A, No 4, recently issued, deals with the use of nickel steel in the *Golden Arrow*, in which Sir Henry Seagrave attained an average speed in two runs in opposite directions of 231 36 miles per hour

The whole of the main and sub frames of the *Golden Arrow* were made of a nickel steel containing 3 5 per cent of nickel and 0 3 per cent of carbon, and it is of interest to note that the side members, which were 19 ft 6 in long, were pressed in one length The very extensive use of this steel, which incidentally was largely used in the brake equipment, indicates its dependability and the wide range of properties obtainable from it with different heat treatments In the normalised condition it will give a tensile strength of 35 tons per square inch, together with 25 per cent elongation A 1¼ in diameter bar oil hardened from 840° C and tempered at 550° C gave a yield point of 42 tons per square inch, a maximum stress of 55 tons per square inch, an elongation of 25 per cent, a reduction of area of 61 per cent, and an impact figure of 56 ft lb

For the main parts of the axles, where a particularly strong material was needed, a nickel chrome molybdenum steel of the following composition was chosen Carbon 0 3 per cent, manganese 0 4 per cent, nickel 3 5 per cent, chromium 0 65 per cent, molybdenum 0 2 per cent This material, which was also used for the gears, gives in the heat treated condition a yield point of 56 tons per square inch, a maximum stress of 63 tons per square inch, 20 per cent elongation, 60 per cent reduction of area, and an Izod value of 67 ft lb This steel gives exceptional uniform properties throughout its cross section when properly heat treated, which, no doubt, influenced the designer in his selection

A 5 per cent nickel case hardening steel containing about 0 1 per cent of carbon was extensively used for parts subject to considerable wear, such, for example, as the swivel pins Refined at 830° C and quenched from 760° C, the approximate tensile figures given are Maximum stress 55 tons per square inch, elongation 15 per cent, reduction of area 40 per cent, with an impact value of 20 ft lb For several parts of the steering mechanism where the stresses involved may be exceptionally high, a nickel chrome molybdenum steel of the following composition was chosen Carbon 0 25 per cent, manganese 0 5 per cent, nickel 3 per cent, chromium 1 2 per cent, molybdenum 0 2 per cent In the quenched and tempered condition, the mechanical properties obtained from this steel are Yield point 62 5 tons per square inch, maximum stress 69 tons per square inch, elongation 19 5 per cent, reduction of area 61 5 per cent, impact value 54 ft lb

For the clutch casing, cover plates, and certain small levers, a nickel chrome steel was specified containing 0 3 per cent of carbon, 3 5 per cent of nickel, and 0 6 per cent of chromium When hardened in oil from 830° C and tempered at 600° C the material gave Yield point 49 tons per square inch, maximum stress 58 tons per square inch, elongation 22 per cent, reduction of area 55 per cent For the clutch centre, withdrawal sleeve, and several other details, a high tensile case hardening steel containing 3 5 per cent of nickel and 1 per cent of chromium was employed After carburising, the steel was given two quenching treatments, one from 830° C and one from 770° C, and afterwards tempered at 200° to obtain a maximum toughness The properties of this material in the form of a 1¼ in diameter bar were Yield point 55 tons per square inch, maximum stress 69 tons per square inch, elongation 15 per cent, reduction of area 45 per cent, and impact value 28 ft lb

It will be appreciated that, apart from the use of nickel steels, the construction of this machine would have been impossible

Investigations in Greenkeeping Problems.

THE St Ives Research Station, Bingley, Yorkshire, which has been established by the British Golf Unions for the purpose of studying greenkeeping problems from the scientific aspect, has issued the first number of the *Journal* of the Board of Greenkeeping Research The development and organisation of the scheme are explained in a foreword, and an interesting account is given by the Director, Mr R B Dawson, of the surroundings and historical associations of the St Ives estate A general discussion follows of the kind of problems confronting the greenkeeper and the line of attack to be undertaken in their solution The station has an ambitious programme, and useful work has already been accomplished

It is realised that the present condition of a turf is largely due to its previous treatment, and that much valuable knowledge may be obtained by collecting and classifying existing information All those interested are invited to contribute their experiences for this purpose An advisory system is already active and a special feature of the *Journal* will be the publication of inquiries dealing with problems of general interest, together with their respective replies Excellent examples of such correspondence are given in the first number

The choice of site for the research station has been fortunate There is a wide range of soils within the relatively small confines of the estate, and further, a difference in elevation from 300 ft to 900 ft is available More than three acres of adjoining land have been acquired and some 400 plots are to be set up to determine the best conditions, both manurial and cultural, for the production of first class putting greens for comparative tests with selected seed mixtures, and for vegetative propagation trials of other grasses, notably *Agrostis canina*, which produces stolons The use of stolon forming grasses for lawns in India is the subject of a further article of interest

Greenkeeping problems have changed considerably in recent years, owing largely to such alterations in practice as the use of compost in place of the heavy roller, and by the introduction of mowers of improved design and numerous chemical fertilisers Hitherto, agricultural methods have usually been employed, and too often the supposition that what is suitable for pasture is equally good for the golf green has proved a fallacy A special type of turf is required for greens free from coarse grasses, weeds, and worm casts For this purpose the effect of various fertiliser treatments will be determined and a thorough, unbiased investigation of the so called acid theory, which maintains that the type of turf required is obtained under acid soil conditions, will also be undertaken Consideration will be given to climatic, physiographic, edaphic, and biotic factors

For the success of the work it is essential that the various golf clubs themselves should give their hearty co operation and such financial support as they are able Later, it is hoped to increase the scope of the work and to extend the investigations to the problems of turf culture peculiar to other sports

Canadian National Research Laboratories

TENDERS have been invited by the Government of Canada for the construction of a National Research Laboratories building that will cost, when finished, approximately three million dollars (Fig 1) Appointment of chiefs to two of the laboratory divisions has been announced

Dr H M Tory, formerly president of the University of Alberta and now the president of the National Research Council, has expressed the view publicly that the new home for research in Canada will be one of the finest to be found in any country It is being built on the banks of the Ottawa River in the capital city Designed in the form of a giant figure ' 8 ', it will stand 60 feet (four stories) high, 418 feet long, and 176 feet deep Two hundred and fifty thousand feet of floor space will be provided Library accommodation will be for 300,000 volumes An assembly hall and associated rooms will be capable of accommodating the staff and the various scientific societies of the Dominion

FIG 1 —Architect s model of the National Research Laboratories building to be constructed by the Government of Canada in the capital city of Ottawa

Plans call for the development of the following divisions the divisions of physics and engineering physics, to the head of which Dr Robert William Boyle, dean of the faculty of applied science at the University of Alberta, has already been appointed, the division of industrial chemistry, to the head of which Dr George Stafford Whitby, professor of organic chemistry at McGill University, has been appointed, the division of economic biology and agriculture, to which Dr Robert Newton professor of field crops and plant bio chemistry at the University of Alberta, is the acting head, the division of industrial engineering, the division of textiles, the division of standards, and such other divisions as improvement in industrial processes, the development of natural resources, and the utilisation of waste require

Dr Boyle was graduated from McGill University in 1906, and from then until 1909, when he received the Ph D degree and the 1851 scholarship, he did research on the properties of matter and radioactivity From 1909 until 1911 he continued his work under the direction of Sir Ernest Rutherford at the University of Manchester Returning to Canada, he lectured at McGill, was appointed assistant professor in 1912, and the same year was made professor in the University of Alberta During the War years, on the recommendation of Sir Ernest Rutherford, Dr Boyle was engaged in research for the Admiralty Board of Invention and the anti submarine division, and in that work he developed important applications of ultra sonics In 1924 he tested apparatus for the detecting of icebergs and the sounding of depths in the Belle Isle Straits

Dr Whitby studied chemistry under Sir William Tilden at the Imperial College of Science and Technology, London, graduating in 1906 with the Frank Hatton prize He was one of the first scientific workers to study the rubber industry, and one of his books thereon, Plantation Rubber and the Testing of Rubber", 1920, has markedly influenced the trend of rubber research In recognition of his contribution in that field, the Institution of the Rubber Industry (Great Britain) recently awarded him the Colwyn gold medal In 1928 the distinction of Officier d Académie was conferred upon him by the Government of France The same year he was president of the Canadian Chemical Association

As assistant director of the division of physics and engineering physics, Prof John Hamilton Parkin, associate professor of mechanical engineering at the University of Toronto, has been appointed to direct the development of national aeronautical research laboratories

Plans for the new National Laboratories building call for completion early in 1931 Meanwhile, temporary laboratory space has been provided

University and Educational Intelligence

EDINBURGH —Dr Alexander Nelson, formerly superintendent of research in the Department of Agriculture in Tasmania, has been appointed lecturer in the Department of Botany and Dr W H McCrea, formerly senior scholar of Trinity College and Isaac Newton fellow in the University of Cambridge, has been appointed lecturer in the Department of Mathematics

MANCHESTER —Prof H J Fleure professor of geography and anthropology in the University College of Wales, Aberystwyth, has been appointed professor of geography

THE Carnegie Foundation for the Advancement of Teaching published in its last annual report an account of an educational inquiry differing from those which

it has hitherto undertaken or promoted, in that it involves tracing the progress of individual students throughout their careers in secondary schools and in college Previous studies have presented in cross section pictures of a situation at a selected time without regard to what went before or followed in the experience of the individual student The investigations, which will necessarily be prolonged through a period of ten years, will embrace the work done in most of the secondary schools and fifty colleges in Pennsylvania, and will, it is hoped, throw light on the validity of currently used methods of classification of pupils according to abilities and interests, on the degree of consistency to be looked for in normal educational growth, and on the actual efficiency of secondary and higher institutions in the organisation and administration of courses of study, the evaluation of educational products, and the rewarding of student effort In tracing the progress of individual students through college, material will, it is thought, be obtained for dealing with difficulties resulting from the kaleidoscopic nature of the elective curriculum and the bewildering variety of personal contact and advice, much of it of a partisan character, to which the college entrant is exposed Much might be done, it is suggested, in "initiating vigorous, wholly avowed and official measures to *understand* the student, and thus to discharge primary obligations of the college" Other matters of general interest in the report are reviews of the rise and present position of endowed foundations in the United States, of professional salaries, and of pension systems

THE League of Nations sets a high value on the dissemination among the children and youth of a knowledge of its aims and achievements The question how this may best be accomplished has been investigated during the past eighteen months by a joint committee representative of English and Welsh education authorities and teachers' professional associations, and the conclusions arrived at as a result of its labours are now published in a pamphlet entitled "Education and the League of Nations" The committee's investigations embraced work done in elementary and secondary schools and in training colleges and university training departments It is in the elementary schools that progress has been most marked In secondary schools there is a disposition to look askance at instruction in the principles and activities of the League as 'propaganda', and to mark time pending adaptation of examination syllabuses by the various school examination authorities to the League's educational policy The teacher training institutions do not seem to have made hitherto an adequate response to Lord Eustace Percy's appeal to the conference of local education authorities in June 1927, when he pointed out that it is above all the students at these institutions for whom opportunities must be provided for acquiring a sound knowledge and a balanced view of the origin and work of the League In its recommendations the joint committee has shown how this ideal may be translated into practice It deals also with such matters as school celebrations, visits to Geneva, interchange of correspondence, school journeys, and the interchange of schoolboys and girls If the minds of the rising generation are to develop the attitude postulated by the Kellogg Pact, it is essential that measures such as those recommended should be adopted, and not only in Great Britain but also among other, including less peace loving, peoples Copies of the pamphlet can be obtained (price 3*d* each) from the office of the League of Nations Union, 15 Grosvenor Crescent, London, S W 1

Historic Natural Events

Jan 1, 1926 Rhine Floods—The river began to rise rapidly on Dec 27, and by Jan 1 stood 32 feet above normal low water at Cologne, the highest level of the Rhine on record Three quarters of the town was under water, which stood 13 feet above the river banks Great damage was done by the Rhine, Scheldt, and Maas in Holland, dykes burst, and wide areas of low ground were flooded The floods were caused by heavy rain on the hills coinciding with high winter temperature and the melting of the snows

Jan 6-7, 1889 Rime—After two days of frost and dense fog in Norfolk, the wind changed to south west, and an unusually thick deposit of ice-needles, up to two inches in length, was formed on the windward sides of exposed objects Many isolated deciduous trees, especially birch, oak, elm, and poplar, were badly damaged, while nearly all overhead telephone and telegraph wires were broken down

Jan 6-7, 1839 Great Storm—On the night of Jan 6-7, western and northern Ireland, northern England, and southern Scotland were visited by an exceedingly violent gale from the south west, probably the worst since that of 1703 Many thousands of trees were uprooted in Ireland houses were unroofed, chimney stacks and walls blown down Many vessels were wrecked and there was great loss of life Menai Suspension Bridge was damaged

Jan 6-7, 1928 Thames Flood—The predicted height of the high tide at London Bridge on the early morning of Jan 7, that is, the height to which the water would rise if the meteorological conditions were normal, was 21 feet above Admiralty datum This is not especially high, for the predicted height sometimes reaches 25 feet The water actually rose nearly six feet above the predicted height, making the highest known level of the Thames in London, and flowed over or through the embankments at several points in the City, Southwark, Westminster, and westward to Hammersmith The low lying riverside districts are below the level of spring tides, and were deeply flooded, while fourteen people, most of whom were sleeping in basements, were drowned

The abnormal rise was due to a 'storm surge' in the southern North Sea On Jan 6 a deep barometric depression travelled rapidly across Scotland in an east south east direction, and in its rear a gale blew from north west and north over the North Sea during the evening, driving a storm wave southwards At 3 P M on Jan 6 the level was 1 6 feet above the normal tide at Dunbar Travelling along the east coast the wave grew in height and reached Southend at 11 P M, raising the level 5 feet Opposite the Thames estuary it divided into three parts, only a small part passed through the narrow Straits of Dover, raising the level about 3 feet, another part travelled north eastwards along the coast of Holland, and the remainder entered the Thames estuary, reaching London at 1 A M on Jan 7 An auxiliary factor in the London flood may have been the high level of the Thames itself, due to heavy rain and melting snow On Jan 7 the flow at Teddington Weir was 9500 million gallons a day, more than double the flow when the river is 'bank high' This river water would, however, be rapidly distributed in the widening estuary, and probably did not contribute more than a few inches to the height of the tide at London Bridge

Jan 7, 1558 'Calais' Storm—It is recorded by Holinshed that at the taking of Calais "began a marvellous sore and rigorous tempest, continuing the space of four or five days together" A severe thunderstorm beat down houses and churches

Jan 7, 1831 Luminosity —Owing to the presence of a kind of luminous mist, print could be read at midnight in Italy and Germany The abnormally light nights continued for a considerable period

Jan 8, 1924 Cyclonic Wave —A small but deep barometric depression passed from Ireland across France It was accompanied by a cyclonic wave which struck the coast of Brittany, causing the sea to rise 3 feet above the level of the highest spring tides, and inundating the coast

Jan 9, 1857 Californian Earthquake —An earthquake, preceded by strong shocks, was felt in southern California, from Sacramento to Fort Yuma, a distance of nearly 600 miles It was most severe at Fort Tejon, in the neighbourhood of which a fissure 40 miles long was formed A remarkable feature of the earthquake was its effect on the rivers of the district The water of the Mokelumne River was thrown on its banks so as to leave the bed bare in one place, while the stream of the Kern River was reversed

Jan 9, 1896 High Pressure over Scotland —During the second week of January, an anticyclone moved westward from the continent of Europe over the British Isles, where it combined with another anticyclone lying off our north west coasts, and increased suddenly in intensity At 8 A M on Jan 9 the barometer exceeded 31 inches (1050 millibars) over the whole of Scotland, the first appearance of that isobar on our weather charts The highest reading, corrected for gravity, was 31 139 inches (1054 5 mb) at 9 A M at Ochtertyre, Perthshire After Jan 9 the whole system moved away south westwards, and on Jan 10 the highest reading was just below 31 inches A remarkable return of high pressure occurred at the end of the month, when the corrected barometer rose to 30 975 inches (1048 9 mb) at Valentia, Ireland A peculiarity of both anticyclones was the mild weather associated with them In the British Isles high pressure in winter is generally associated with frost and fog, but on both occasions in January 1896 temperature was almost everywhere above the freezing point

Jan 10, 1608 Severe Winter —The winter of 1607–8 was probably the most severe on record in western Europe, and was long remembered as "the great winter" In England the cold continued from Dec 5 to Feb 14, but on the continent of Europe it continued until the middle of March On Jan 10, in a church in Paris, the wine froze in the chalice All the great rivers of western Europe were frozen, fires were lit on the Thames, and the Zuider Zee was crossed from Harlingen to Amsterdam Many human beings, cattle, and young trees were killed The break up of the ice was followed by great floods

Jan 10–15, 1820 Great Cold —A short period of very intense cold occurred from England to Italy Arago remarks that on Jan 10 a great number of mulberry trees split along their whole length, mostly trees from ten to thirty years old The openings remained until the end of the frost, after which they healed up and the trees survived An observer at Tunbridge Wells recorded that on Jan 15 the thermometer fell to −10° F, "the lowest by fourteen degrees that I ever remember it" The details of this thermometer and its exposure are not known, so that this reading cannot be compared with modern 'records'

Jan 11, 1900 Haloes and Mock Suns —Brilliant optical phenomena were visible over the greater part of south east England during the morning The common halo of 22° and the rarer halo of 46° were both visible and brilliantly coloured Above both haloes were arcs of contact, and a mock sun appeared to the right of the true sun on the 22° halo Some observers also saw a second mock sun to the left of the true sun

Societies and Academies

LONDON

Geological Society, Dec 18 —Frederick Walker The geology of the Shiant Isles The Shiant Isles form a small uninhabited archipelago in the North Minch, some five miles east of the Park district of Lewis The group is made up almost entirely of crinanite sills separated by relatively thin argillaceous strata which have undergone considerable contact-alteration, but the fossil content of which (ammonites, belemnites, and one species of *Inoceramus*) assigns them to a low position in the Upper Lias The two largest islands are each over a mile in length, and are joined by a shingle beach A third large island lies about a mile to the east, and is also to a great extent made up of a single thick sill of crinanite East of this island, however, the crinanite passes gradually into syenite, towards the centre of the sill, the thickness of the alkaline rock being at least 60 feet The age of the igneous activity is almost certainly Tertiary, and is probably the same as that of the Trotternish sills in Skye Although glacial striæ are not seen on the islands, their general aspect indicates a flow of ice from south to north during the Glacial Period

DUBLIN

Royal Irish Academy, Dec 9 —Gertrude Connolly The vegetation of southern Connemara The paper dealt with the vegetation of a large area lying west of Galway between the sea and the mountains—a vast tract of almost unbroken bog This area had not previously been examined botanically save along its margins Rainfall and humidity are very high, and in consequence the bogland is perennially extremely wet and difficult to explore The vegetation proved to be limited in number of species, and alternated mainly between those of drier and wetter bog

LEEDS.

Philosophical and Literary Society, Dec 10 —G W Brindley (1) On the dielectric constants of helium and argon The dielectric constants of these gases are calculated from the charge distributions obtained by Hartree, using an expression due to Pauling and others for the dielectric constant of an electron in a central field of charge Z^1e, Z^1 being chosen so that r^4 is the same for the hydrogen like distribution as for the Hartree charge distribution The calculated value of $(K-1)$ for helium agrees well with the experimental value, but the calculated value for argon is not good —(2) Note on the accuracy of constants in an optical dispersion formula The accuracy is considerably less than the accuracy of the experimental values of the refractive index In the case of methane, if $(\mu-1)$ is assumed accurate to 1 part in 50,000, the constants in the formula $(\mu-1)=C/(p^2-n^2)$ can only be accurate to about 1 per cent, owing to the form of the dispersion curve and the limited range of experimental data —(3) Note on distribution of charge with carbon atom (2) A continuation of a previous paper, pointing out that some new experimental measurements of the X ray scattering factor F are in good agreement with the theoretical value given in Part 1 —R Whiddington Note on the electron gun Experiments are described in which the electron beam from a gun is used in a cathode ray oscillograph and is found to possess a velocity much less than that calculated from the applied potential A curious shortening of the beam under certain conditions was also observed —J E Roberts and R Whiddington Note on inelastic electron

collisions in oxygen at low pressures Experiments are described in which electrons of about 100 volts velocity traverse oxygen gas at low pressure Quantum losses are observed and certain interpretations suggested —**A E Battye** and **H M Dawson** The nature of the reaction between phorone and iodine and the influence of the acidity of the aqueous medium on the reaction velocity The rate at which iodine disappears from the reaction mixture is determined by the velocity of the keto→enol transformation of the phorone The variation of the speed of the reaction in buffer solutions ranging from *p*H 3 to *p*H 9 shows that the major catalytic effects are due to the joint action of the hydrogen and hydroxyl ions The graph of the velocity against *p*H gives a catenary curve —**J Grainger** (1) The appearance of bean mozaic in England A short descriptive note on an infection in dwarf kidney beans at Weetwood, Leeds The symptoms of the malady are identical with those of bean mozaic described in America by Reddish and Stewart, Fajardo and others —(2) An attempt to cultivate the virus of tobacco mozaic *in vitro* Two experiments on the cultivation of the virus of tobacco mozaic *in vitro* are described One followed the method of Olitsky, and in the other a chloroplast suspension was employed Neither showed an increase in virus concentration during cultivation —**W H Pearsall** and **Alice Wright** The proportions of soluble and insoluble nitrogenous materials in fresh and dried plant tissues An examination has been made of the effect of drying leaves by the method of Link and Tottingham, upon the distribution of protein and non protein nitrogen The amount of non protein nitrogen extracted by 60 per cent alcohol is only slightly increased (1 5 2 0 per cent of total) by this method of drying The variations in the ratio of protein nitrogen to soluble nitrogen in dried leaves follow those in fresh leaves, but are proportionately lower In leaves having a higher water content there is no increase in the relative amount of hydrolysis on drying —**T M Naylor** and **A G Abel** An analysis of the link gear of an old beam engine A short illustrated description of the link gear of an old beam engine constructed by Boulton and Watt in 1792 and dismantled in 1888

LENINGRAD

Academy of Sciences (*Comptes rendus*, No 18) —**N N Nasonov** Contribution to the freshwater fauna of *Turbellaria rhabdocœlida* of Japan Fourteen species have been found on the island Chondo, several of them new to science One of the latter, *Macrostomum saifunicum*, is very near to the American *M sensitivum* —**K K Flerov** Some new data on *Capreolus* of eastern Asia Supplementary distributional data are given (see author's paper in *C R*, p 479, 1928), and descriptions of young animals of all species are presented —**M Galadzhiev** and **E Malm** The influence of some physico chemical factors on marine water Protozoa Studies on the influence of oxygen, hydrogen, and carbon dioxide in the water on marine Protozoa indicate that the effects may be very different even when the *p*H value is the same The main physiological factor proved to be the carbonic acid, towards which there is a specific reaction, for example, the Protozoa of the family *Tintinnoidea* are killed within 40 seconds in sea water saturated with carbon dioxide, while *Metopus sigmoides* can survive up to 9 days —**A B Verigo** An apparatus for the determination of the electrostatic capacity of electroscopes An apparatus is described which can be fitted on to the lid of an electroscope and permits of determining its capacity within 1 2 per cent —**A B Verigo** A rotary apparatus for increasing electric tension The apparatus described increases the tension up to five times

ROME

Royal National Academy of the Lincei Communications received during the vacation —**G Abetti** and **B Nováková** Structure of the line $H\alpha$ and period of rotation of the solar chromosphere A note on the dissymmetry of the line $H\alpha$ at the sun's border, as determined by spectrograms obtained at Arcetri, was published in 1926 A large number of measurements made in 1927 and 1928 give the result $H\alpha_3 - H\alpha_2 = -0\ 059 \pm 0\ 002$A, the centre of the dark component $H\alpha_3$ being hence displaced with respect to $H\alpha_2$, together with the emission components, by 0 059 A A series of spectrograms comparing opposite edges of the sun at various latitudes shows that the velocity of the hydrogen layer giving rise to the line $H\alpha_3$ is greater than that corresponding with $H\alpha_2$, that of the inverting stratum lying between the two The equatorial acceleration is sensibly the same for the three layers The dissymmetry appears to be greater in the east than in the west —**D Mercogliano** The quadratic complexes containing the congruence of the axes of a cubic hump and the conditions for two binary cubics having two common roots —**E Persico** and **F Scandone** The Hall effect with extended electrodes (1) —**M Merola** *R Scuti* A series of 85 photometric observations on this variable, made at Capodimonte between Aug 10, 1927, and Dec 6, 1928, indicate two maxima and four minima, and confirm the irregularity of the period and of the light curve, in accordance with the observations of Jacchia, Spears, Peltier, Carr, and Ford, and with the discussions of Sawyer and of Campbell —**F de Carli** Viscosity isotherms of binary mixtures (4) The system, benzaldehyde sulphur monochloride Thermal analysis of this system being impossible, since all the mixtures give, on cooling, viscous masses with scarcely appreciable velocities of crystallisation, use has been made of the viscosity The maximum divergence of the observed from the calculated viscosities occurs with mixtures containing 60 per cent of the aldehyde, the formation of the compound $2C_6H_5CHO, S_2Cl_2$ being thus indicated —**A Ferrari** and **A Inganni** The importance of the crystalline form in the formation of solid solutions (6) Thermal and X ray analysis of the anhydrous systems $CaCl_2 - CoCl_2$, $CaCl_2 - FeCl_2$, $CaCl_2 - MnCl_2$, and $CaCl_2 - CdCl_2$ Cobaltous and ferrous chlorides give eutectics with calcium chloride at 614° and 592°, the molecular proportions of the calcium salt being 54 3 and 44 5 per cent respectively Manganese and cadmium chlorides give mixed crystals with calcium chloride in all proportions, and these crystals, even with small proportions of one of the components, decompose into their constituents at about 475° and 414° respectively The behaviour of these systems points to a difference between the structure of calcium chloride and those of the rhombohedric chlorides of cobalt, iron, magnesium, manganese, and cadmium, since none of the systems shows the complete miscibility devoid of maximum and minimum solidification temperatures characteristic of isomorphous mixtures Assuming Goldschmidt's values, the radii of the ions are Co^{++} 0 82 A, Mg^{++} 0 78 A, Fe^{++} 0 83 A, Mn^{++} 0 91 A, Cd^{++} 1·03 A, Ca^{++} 1 06 A —**G Piccardi** Spectrographic detection of bismuth in the ashes of animal organisms If certain modifications are made in the circuit, the detection of very small amounts of bismuth is possible by means of lines in the ultra violet region of the spark spectrum, especially the line λ3067, which is observable with solutions containing only 0 001 per

cent of the metal —**G Scagliarini** and **P Pratesi** The colour reaction between sodium nitroprusside and creatinine Two possible formulæ are suggested for the ruby coloured substance formed, according to Weyl's test, by the action of sodium nitroprusside on creatinine in alkaline solution —**G Scagliarini** and **G Tartarini** Additive compounds of halides of bivalent metals with organic bases (7) The following hexamethylenetetramine compounds are described $2MgCl_2, 16H_2O, 5C_6H_{12}N_4$, $2MgI_2, 16H_2O, 5C_6H_{12}N_4$, $2MgBr_2, 16H_2O, 5C_6H_{12}N_4$, $2CaCl_2, 8H_2O, 5C_6H_{12}N_4$ —**Giambattista Dal Piaz** Geological notes on the region of the Aurine Alps and of the Giant Vedrettes (Upper Adige) —**A Palombi** The biological cycle of *Diphterostomum brusinæ* Stossich (Digenetic trematode fam Zoogonidæ Odhner) —**M Tirelli** Opening of Malpighian tubes in the meso intestine —**G Mezzadroli** and **E Vareton** Action of Wood's light on the germination of seeds and on the growth of plants Experiments on barley, beans, peas, and maize show that Wood's light exerts a favourable influence on the germination of seeds and on the growth of plants when applied for 15 minutes to some hours per day The action is especially favourable during the early stages of development, the plants being increased in number, vigour, and height —**G Mezzadroli** and **E Vareton** Comparison between the actions exerted by ultra short electromagnetic waves (λ2 3 mm) and by the Lakhovsky oscillating circuit on the germination of seeds and the growth of plants The favourable influence of electromagnetic waves on seeds and plants is similar to, but more marked and more constant than, that of the Lakhovsky circuit and is a function of the intensity of the waves them selves —**P Pasquini** and **G Meldolesi** Investigations on radio sensitiveness in the development of the eggs of amphibia (1) Differential radio susceptibility of the various embryonic stages (Anurans) —**M Curzi** A new and serious disease of maize During last June certain maize was attacked, with loss of about 80 per cent of the plants, by a malady which resulted in necrosis at the base of the stalk The plants affected fell to the ground and there continued to grow without any sign of withering, communications between the aerial and subterranean organs remaining uninterrupted The disease is due to a mould, probably communicated from the previous year's crop of beet —**Constantino Gorini** Acido proteolytic enzymes of tanning

SYDNEY

Royal Society of New South Wales, Nov 6 —**A R Penfold** and **J L Simonsen** Note on the leaf oil from *Dacrydium Franklinii* Hooker The chemical composition of the terpene fraction as previously revealed was confirmed, but the principal terpene for which the name dacrydene was proposed has now been shown to consist of Δ ⁴carene and beta pinene The former is a new bicyclic terpene first isolated by Dr Simonsen from Indian pine oil The solid diterpene, phyllocladene, was also isolated from this oil —**A R Penfold** and **F R Morison** The essential oils *Melaleuca decora* (Salisbury) Druce and *M Nodosa* var *Tenuifolia* (de Candolle) from the Port Jackson District (1) The principal constituents of oil from the former are *d* α pinene (50 60 per cent) and sesquiterpenes (25 30 per cent), with small quantities of α terpineol, dipentene, and sesquiterpene alcohol The oil from the later yields cineol (40 55 per cent), α pinene, dipentene, α terpineol, sesquiterpene, etc Both these species of paper bark tea tree occur in extensive areas close to Sydney, but the rapid advancement of settlement foreshadows their extermination at an early date

Diary of Societies

FRIDAY, JANUARY 3

PHYSICAL SOCIETY (at Imperial College of Science), at 5

INSTITUTION OF MECHANICAL ENGINEERS, at 6 —Eng Vice Admiral R W Skelton Progress in Marine Engineering (Thomas Lowe Gray Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section), at 7 —J G Wellings and C G Mayo Instrument Transformers

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group—Informal Meeting) at 7

JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7 30 —F T Wood Speedy Draughtsmanship

SATURDAY JANUARY 4

ROYAL INSTITUTION OF GREAT BRITAIN (at Institution of Electrical Engineers), at 3 —S R K Glanville How Things were done in Ancient Egypt (Christmas Lectures) (4) Boats and Furniture

MONDAY, JANUARY 6.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 3.30.—Major C K. Cochran Patrick Places seen from the Air (Christmas Lectures) (1).
INSTITUTION OF AUTOMOBILE ENGINEERS (Western Centre) (at Merchant Venturers Technical College, Bristol), at 7 —W L Morgan Organisation of Public Service Motor Vehicle Repairs and Maintenance Systems
BRADFORD TEXTILE SOCIETY (at Midland Hotel, Bradford), at 7 30 —W H. Ambler Single Dry Spun Yarns
ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8 —Dr R. Unwin Regional Planning, with Special Reference to Greater London.
SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Chemical Society), at 8 —C J J Fox The Micelle Chemistry of Cellulose —J A Pickard Metafiltration.
TWICKENHAM LITERARY AND SCIENTIFIC SOCIETY (at Free Library, Twickenham), at 8 —Dr E. H. Rayner Power Transmission at High Voltages

TUESDAY, JANUARY 7

ROYAL INSTITUTION OF GREAT BRITAIN (at Institution of Electrical Engineers), at 3 —S. R. K Glanville How Things were done in Ancient Egypt (Christmas Lectures) (5) The Workshops
BRITISH PSYCHOLOGICAL SOCIETY (Education Section) (jointly with Nursery School Association) (at University College), at 5 30 —Principles and Practice in Nursery School Education —Mrs S. Isaacs What the Nursery School can do for the Young Child —Miss Lillian de Lissa Nursery School Aims and Problems
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group), at 7 —L. Richmond The Modern Tendency in Art
INSTITUTION OF AUTOMOBILE ENGINEERS (Graduates Meeting) (at Broad gate Café, Coventry), at 7 15 —J R. Harnott The Rigid Six wheeled Vehicle
INSTITUTION OF AUTOMOBILE ENGINEERS (at Royal Society of Arts) at 7 45 —T W Cooper Roller Bearings
TELEVISION SOCIETY (at Engineers Club, Coventry Street), at 8 —W S Newton Photographic Problems of Picture Telegraphy

WEDNESDAY, JANUARY 8

GEOLOGICAL SOCIETY OF LONDON at 5 30 —Dr Stanley Smith On some Valentian Corals from Shropshire and Montgomeryshire with a Note on a New Stromatoporoid —Dr Stanley Smith The Carboniferous Inliers at Codrington and Wick (Gloucestershire).
INSTITUTION OF HEATING AND VENTILATING ENGINEERS (at 20 Hart Street, W C 1), at 7 —C A Masterman Combustion, Wind and Flue Equipment.
ELECTROPLATERS AND DEPOSITORS TECHNICAL SOCIETY – E. Downs Electrolytic Gold Refining

THURSDAY, JANUARY 9

ROYAL INSTITUTION OF GREAT BRITAIN (at Institution of Electrical Engineers), at 3 —S R K Glanville How Things were done in Ancient Egypt (Christmas Lectures) (6) Hieroglyphs
LINNEAN SOCIETY OF LONDON, at 5 —W H Thorpe Further Notes on Biological Races in *Hyponomeuta padella* (Linn).—J T Cunningham The Origin of Adaptations
INSTITUTION OF ELECTRICAL ENGINEERS at 6 —T W Ross and H G Bell Recent Developments in the Protection of Three Phase Transmission Lines and Feeders.
ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 6.30 —R. McKinnon Wood The New American Wind Tunnel
INSTITUTION OF ELECTRICAL ENGINEERS (Mersey and North Wales (Liverpool) Centre) (at Liverpool University), at 7
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Colour Group—Informal Meeting), at 7 —F W Sharp Dyebro —F R Newens A New Formula and Method for 3 colour Carbo
INSTITUTION OF ELECTRICAL ENGINEERS (Dundee Sub Centre) (at University College Dundee) at 7 30 —G H Chalmers Lubrication
INSTITUTE OF METALS (London Local Section) (at 83 Pall Mall) at 7 30 —G Mortimer The Aluminium Industry
SOCIETY OF CHEMICAL INDUSTRY (Bristol Section) (at Bristol University), at 7 30 —F G Conyers Wood Distillation
OIL AND COLOUR CHEMISTS ASSOCIATION, at 7 30
INSTITUTE OF BREWING (North of England Section) (at Midland Hotel, Manchester) —Dr L H Lampitt The Historical Development of Work on Yeast.
INSTITUTE OF CHEMISTRY —Dr A M Bronte The Medical Witness
NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Tees Side Branch).—J W Hobson Locomotives for Industrial Purposes and their Maintenance
INSTITUTION OF THE RUBBER INDUSTRY (Birmingham and District Section) (at Grand Hotel, Birmingham).—H Standring Outstanding Features in the Progress of the Rubber Industry

FRIDAY, JANUARY 10

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 3 30 —H G Watkins By Canoe and Dog Sledge in Labrador (Christmas Lectures) (2)
ROYAL SOCIETY OF ARTS (Indian Section), at 4 30 —Sir Basil P Blackett The Economic Progress of India.
ROYAL ASTRONOMICAL SOCIETY, at 5 —E A. Kreiken The Frequency of Double Stars of Different Spectral Types and Absolute Magnitudes —J Jackson The Shortt Clocks of the Royal Observatory, Greenwich with Special Reference to the Effect of Variation in Arc —H Jones Deviations from Boyle's Law in Stellar Interiors.
MALACOLOGICAL SOCIETY OF LONDON (in Zoological Department, University College), at 6.
NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute, Newcastle-upon Tyne), at 6 —L. C Burrill Design and Construction of the Rail-car carrying Steamship *Seatrain*
SOCIETY OF CHEMICAL INDUSTRY (Manchester Section) (at Engineers Club, Manchester), at 7 —Dr E K Rideal Some Aspects of Surface Chemistry and their Industrial Implications.
INSTITUTION OF ELECTRICAL ENGINEERS (North Western Centre) (at Free Trade Hall, Manchester), at 7 —Capt P P Eckersley Broadcasting by Electric Waves (Faraday Lecture).

OIL AND COLOUR CHEMISTS ASSOCIATION (Manchester Section) (at Milton Hall, Manchester), at 7 —Prof T P Hilditch Recent Research on Fats bearing upon the Drying of Oils in Paint and Varnish.
GEOLOGISTS ASSOCIATION (at University College), at 7 30 —J Pringle The Geology of Ramsey Island (Pem).—*Papers to be taken as read* —The Palæobotany of the Kent Coalfield, Dr R. Crookall and J Pringle, The Preparation of Thin Sections of Friable and Weathered Materials by Impregnation with Synthetic Resins, R. J Schaffer and P Hirst
JUNIOR INSTITUTION OF ENGINEERS, at 7 30 —H J N Riddle The Track Circuit in Railway Signalling
SOCIETY OF CHEMICAL INDUSTRY (Chemical Engineering Group) (at Burlington House), at 8 —J R Booer Autogenous Welding in Chemical Works
PHILOLOGICAL SOCIETY (at University College), at 8 —G G Loane Notes on N E D
SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (at Cardiff).—E. H Williams Graphitic Lubricants

PUBLIC LECTURE.

TUESDAY, JANUARY 7

PHILOSOPHICAL HALL, LEEDS at 6 —E G Boulenger Behind the Scenes of the Zoo Aquarium (Christmas Lecture).

CONFERENCES

JANUARY 3

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION (at University College), at 2 30 —K D Young School Sanatoria
BRITISH ASSOCIATION FOR PHYSICAL TRAINING (at University College), at 5 30 —Dr D J Harris The Electrical Phenomena of Muscle

JANUARY 3 AND 4

SCIENCE MASTERS ASSOCIATION (at Imperial College of Science)
Friday, Jan 3, at 9 30 A M —W Corbridge Lecture Demonstration on Some Home Made Physical Apparatus
At 10 45 A M —Dr J C Munro Industrial Biology (Lecture)
At 12 —Prof Truscott and others Discussion on Openings for College Trained Men in the Mineral Industry
At 5 15 —Discussion with the Physical Society on Examinations in Practical Physics.
At 8 15 —Discussion on School Certificate Biology
Saturday Jan 4 —Visits to the National Physical Laboratory and the Government Laboratory

GEOGRAPHICAL ASSOCIATION (at London School of Economics)
Friday, Jan 3 at 10 A.M —Discussions —The Physical Basis of Geography in Independent Schools Opened by B B Dickinson —Geography and the Training of Teachers Opened by T Herdman
At 11 30 A.M —Col H L. Crosthwait Air Survey (Lantern Lecture)
At 2 30 —The Geography I was Taught, by Members of the Association
Saturday, Jan 4 at 10 30 A M – Sir E J Russell Agricultural Developments in South Africa (Lantern Lecture).
At 11 45 A M —Dr Vaughan Cornish National Parks.

JANUARY 6 AND 7

MATHEMATICAL ASSOCIATION (Annual Meeting) (at London Day Training College)
Monday, Jan 6 at 4 —R I Gimson and others Discussion on Arithmetic of Citizenship
At 5 30 —Prof S Chapman The Use of Spherical Harmonic Functions in Mathematical Physics
Tuesday Jan. 7 at 10 A M —G W Spriggs and others Discussion on Problems of Individual Education with Special Reference to Work in Mathematics
At 11 45 A M —Prof W M Roberts Gunnery and some of its Mathematical Problems (Lecture),
At 2 30 —Dr W F Sheppard Mathematics for Study of Frequency Statistics
At 3 45 —Miss Hilda P Hudson and others Discussion on The Mathematician in Ordinary Intercourse

JANUARY 7

NATIONAL COUNCIL FOR MENTAL HYGIENE (at University College) at 3 —Discussion Preventable Mental and Physical Strains of School Life.

EXHIBITION

JANUARY 7, 8, AND 9

ANNUAL EXHIBITION OF THE PHYSICAL SOCIETY AND THE OPTICAL SOCIETY (at Imperial College of Science) from 3 to 6, and from 7 to 10
Jan 7, at 8.—Lord Rayleigh Iridescent Colours in Nature from the Standpoint of Physical Optics (Lecture)
Jan. 8 —S. G Brown Gyro Compasses for Gun Fire Control (Lecture),
Jan. 9 —Sir Ambrose Fleming Television, Present and Future (Lecture)

School Certificate Biology

THERE are indications that, in the not far distant future, there may be removed from our courses of education the reproach that in England alone of practically all civilised countries is it possible for a student at the age of eighteen or nineteen to leave school destitute of any teaching in the fundamental processes of life Biology as a subject in the School Certificate Examinations has received attention at the Headmasters' Conference, a report containing suggestions for a syllabus has lately been published by a committee of the British Association, and a committee appointed by British zoologists "to consider the position of animal biology in the school curriculum and matters relating thereto" has also reported upon the subject It is, too, a hopeful sign that nearly all examining bodies granting school certificates now include biology among the examination subjects, and further, that the number of candidates offering it, though still a very small percentage of the whole, shows a steady increase

It is clear that in formulating a syllabus and in determining the scope of this examination, the opinion of those engaged in teaching biology at schools should carry great weight They are familiar with the conditions prevailing in the schools, and, far better than professors and lecturers at the universities, can judge not only what is feasible, but also what is within the mental reach of pupils at the age of sixteen or thereabouts The Science Masters' Association was thus well advised in arranging a discussion on school certificate biology during its recent conference at the Imperial College of Science, and in endeavouring to secure a consensus of opinion regarding the purpose of such biology and the character of the examination itself The propositions laid down in order to focus discussion were as follows

(*a*) Biology should be a subject in which it is possible to obtain "credits", and must not be regarded as a "soft option", but nevertheless it is obvious that the same number of hours will never be allotted to it as to mathematics, languages, etc

(*b*) School Certificate Biology is intended to be for general education purposes, and not as a preparation for specialised Higher Certificate work

(*c*) The examining bodies should keep their detailed syllabuses as short and general as possible

(*d*) A knowledge of Chemical and Physical processes is not to be demanded except in so far as they are necessary for an elementary understanding of definite biological principles

(*e*) There should be no practical examination, demonstration lectures taking the place of individual practical work

(*f*) A syllabus should include

1 The fundamental principles of plant physiology and propagation, but without any unnecessary anatomical details
2 The elements of human physiology and dependence of all animal life on the green plant for its source of energy
3 The carbon and nitrogen cycle, and the part played by bacteria and fungi in nature
4 Amœba, Hydra, and the Frog (These should be the only actual animal types mentioned)
5 Structure of a regular flower to show pollination and fertilisation
6 An elementary knowledge of, at least, the evidences of Evolution, and the principles of Heredity

(*g*) Definite "Field Work" is impossible for boys at this stage during school hours

The suggested syllabus is commendably brief, and appears to include all the essentials, though teachers will probably allude to other than the three animals specified in (*f*) 4, and to some of the more striking irregular flowers when dealing with pollination, and will find occasional expansion of this bare minimum desirable There is clearly no intention to restrict the teacher rigidly to the scheduled items

The second of the above propositions (*b*) needs strong emphasis In the past there has been too great a tendency to teach elementary science on lines suited to students destined later to specialise in science, and to disregard the fact that an enormous majority of the pupils at this stage are not so destined It is not unnatural for a teacher, especially for a young one who has but recently completed an advanced course at the university, to teach on the lines along which he himself, a specialist, has been taught But the temptation must be resisted Prior to and up to the school certificate examination, all the science teaching should be solely for purposes of general education and culture It should pave the way for the future citizen to take an intelligent interest in the progress of modern thought, and in social legislation, hygiene, and the general welfare of mankind, and should render possible, nay probable, a fuller, happier life, a better use of the environment, and a keener appreciation of its beauty and mystery

These considerations, coupled with the reference to chemical and physical processes in the fourth proposition (*d*), raise the question—Is the present policy of allowing chemistry, physics, or biology to be offered as separate subjects in the school certificate examinations wise and educationally sound? Their very separation savours of specialisation A candidate offering biology must have had some instruction both in chemistry and in physics, but the converse is not true—greatly to the loss of the candidates concerned

Now in other school certificate subjects candidates are really examined on work that has been spread over several years, dating back in some cases to the very commencement of their education, though perhaps pressure of the examination 'screw' has been applied only for a year or two preceding the examination The above suggested syllabus, however, and some of those prescribed by examining bodies for other scientific subjects, can be covered satisfactorily in three or four terms, with a time table allotment of about three hours per week It would assuredly be preferable that the period during which the science has been studied should be more nearly commensurate with that pertaining to other subjects of the examination This end could be achieved if in the school certificate the only science allowed were 'general', and if the 'general science' were based on biology, broadly conceived as the science of life for all

The Science Masters Association's syllabus affords abundant opportunity for digressions into the realms of chemistry and nearly all branches of physics Such digressions might extend over several weeks, or even a whole term, and would certainly provide ample material for individual experimental work Even with the short syllabus suggested, the biology master worth his salt is bound to refer in teaching to a large number of topics that already find a place in the elementary text books of chemistry and physics, for example, the properties of air and of water, oxidation, conservation of energy, and so on Thus the digressions would have as their objective the elucidation of many of the properties of living matter, and the whole course would gain in coherence and in interest Such a syllabus might well serve as the nucleus of a two year or three year course, according to the number of hours per week assigned in general science for the school certificate examination The standard, measured by the amount of ground covered, should be low, but a high degree of accuracy should be demanded It is only thus that sure foundations are laid

To carry out such a reform in the teaching will require careful co ordination of the work, and loyal co operation among the teachers in each school Such co ordinated schemes of science teaching are, and have been for some years, in operation in nearly all the countries of western Europe The like should surely not be beyond the organising ability of the schools and universities of England

Statistical Method in the Social Sciences

The Statistical Method in Economics and Political Science a Treatise on the Quantitative and Institutional Approach to Social and Industrial Problems By Prof P Sargant Florence (International Library of Psychology, Philosophy and Scientific Method) Pp xxiv + 521 (London Kegan Paul and Co , Ltd , New York Harcourt, Brace and Co , 1929) 25s net

UNTIL just recently, statistics have not been regarded as a very essential part of economics or political science, or indeed of any of the social sciences, but have been looked upon as rather dull and drab accessories, to be relegated to the end of the book as mere appendices There is scarcely a single table or diagram in any of the older classics, and although measurability, in Lord Kelvin's well known dictum, was supposed to be the hall mark of any true science, it was rather furtively hoped that economics, at all events, if not the other members of the social group, could somehow be shuffled through the portals into the world of science without possessing any great store of measurable data

There has been some improvement, during the last few years, in the introduction and use of statistical method in economics, but Prof Sargant Florence is probably right in saying that attempts at the scientific study of mankind in the economic and political spheres have largely broken down owing to faulty liaison work between the non statistical and the statistical methods of approach "The mathematical statistician is out of touch with the expert in a special field, and the experts, whether economists, political scientists, or sociologists, generally fail to make use of statistical methods and busy themselves with repeating the same unverified hypotheses, or pitting one equally unverified hypothesis against another " The trail so brilliantly blazed by Jevons has not been adequately followed up, and though there has been considerable advance in the study and appreciation of statistics and a vast output of statistical studies and compilations bearing more or less directly on different fields of economics, little real fusion of economic theory with measured observations has been achieved There have been, it is true, some notable exceptions among the economists, such as H L Moore, Wesley Mitchell, Taussig, Cassel, Pigou, and Marshall, who have combined a profound knowledge of economic theory with sound statistical skill, but in the main, the argument holds that modern economics is still largely concerned with the elaboration or more or less plausible theories insufficiently supported by verifiable data

A further criticism which seems well justified—although it has always been easy enough to pile up criticism against the economist and all his ways, justifiable or not—is based on the attempts to separate the economic from the political, and to make two entirely distinct entities of economics and political science For purposes of specialised study this may be desirable, but despite the dictates of specialism, which may sometimes be followed too slavishly and fearfully, it cannot be too strongly insisted that the social sciences at all events should, so far as possible, be studied as one Certainly economics and political science cannot be separated for long, and this becomes more clearly apparent when their statistical foundations and structure are envisaged It is the supreme merit of Prof Sargant Florence, when planning his great work, that he has co ordinated and correlated in a wonderfully skilful manner, the highly complex data of economics and political science, and used the statistical approach for his purpose in such a way that the result is a triumph in homogeneity, a noble architectural pile, deeply impressing the observer with its massive strength, completeness, well balanced proportions, and unity

Various devices have been sought, but seldom found, for counteracting the evils of specialism in modern science, for providing a higher and more comprehensive viewpoint, for seeing a science or branch thereof in its remoter connexions, for co ordinating related parts Philosophy has sometimes been called upon to fulfil this important rôle , but that statistical method also could be used to serve the same end, though to a lesser degree, was an original and brilliant conception which Prof Florence has worked out with indefatigable perseverance, amazing skill, and comprehensive grasp of a vast field in economics and political science The expert statistician may not always agree with the author in certain details of technique, some of which he himself admits may be heretical , and truly, in such an elaborate technique, even though higher mathematics is eschewed, there are bound to be some controversial points for the hyper critical specialist , but for the general reader, for the general student of economics and political science, the work is invaluable as a veritable storehouse of the latest research in statistical method as applied to these particular social sciences It sums up the work of all the best authorities, but most of it is the author's own, is fresh, original, stimulating, and written in that lucid and charming style that

one has been led to expect from Prof Florence Its breadth and thoroughness are remarkable, for it is very much more than a mere text-book on statistical method It is also a comprehensive treatise on economic and political science so far as these are amenable to statistical treatment, and the extent of that amenableness is much greater than is commonly supposed, as may be gathered from the following brief summary of contents, taken from Chaps i and ii

The function of economics and political science is the discovery and study of fact in the indicative mood, free from moral implications, and from optative or imperative attitudes Scientific knowledge must first be obtained before it can be applied to produce the results desired for the good of mankind

In the pursuit of knowledge the primary function of statistics is to describe item facts summarily Such descriptions may substitute experience for unfounded or ill founded assumptions, and verify or refute economic or political theory, or suggest pertinent generalisations of their own for theory to interpret The statistical approach can be shown to be not inferior to deductive reasoning as mental discipline

The focus and scope of economics and political science are described, and a further subdivision of the complete field is suggested into (*a*) economics, (*b*) political science proper, (*c*) political economics, and (*d*) economic politics This method of sub dividing is perhaps open to criticism Economic, political, and institutional inter relations are next dealt with, thus completing Part I In Part II are described very fully the methods and technique of statistical measurement The principles of classification and orientation demanded by qualitative differences and complexities are given in Part III, together with the principles and pre cautions to be observed in representing qualities through quantitative index numbers This part includes a discussion of both statistical and non statistical methods of causal interpretation, such as isolation of factors, experiment, and introspection In Part IV we proceed to tackle the intricacies of economic theory, modified in certain important respects, especially in the direction of flexibility, in order to suit statistical requirements The statistical approach starts from item facts, but may use established theories as plausible working hypotheses Eventually, statistically tested theories or theoretically interpretable statistics may perhaps be found to rest upon a solid and exact physical or psycho physiological basis

In political science there is no body of accepted theory but merely some structural and functional analysis, and the statistician must build up his own theories empirically by the correlation of varieties of structure, procedure, and transactions, and by the correlation of varieties of objectively distinguishable procedures such as ruling, work-sharing, and manning

It will be seen that Prof Florence goes as deeply as is possible for a statistician to go in investigating the complex phenomena of mankind's behaviour in the economic and political spheres, even to the extent of finding a measure for the psycho-physiological (Why not psychological simply ?) factors of exchange, but since he has necessarily excluded all ethical and moral implications, as ruthlessly indeed as the American economist, General Walker, has done, and adhered faithfully to the indicative mood, the inquiry would seem to stop short at its most interesting and practically valuable stage

Presumably it is left for the social philosopher to expatiate in the optative mood, and the statesman in the imperative mood The former, with out-stretched arms and full of a burning zeal for the welfare of mankind, seeks persuasively to inculcate political wisdom wherever this is to be found, whilst the latter imperatively thunders forth his commands Both should be as well grounded in the statistical approach to economics and political science as Prof Florence, but is this possible ? Or is it too much to hope that Prof Florence himself will work out for us the ethical and moral implications, and supplement and co ordinate such of these implications as are already scattered about in some of his other books, for example, in "Economics and Uplift", continuing on a larger and more comprehensive scale the work already begun by Sir Wilfrid Ashley, Prof Cunningham, and one or two others ? This would be a real contribution to the clarification of politics, establishing it on a more scientific basis, and a contribution also to the true art of statesmanship which cannot possibly be considered apart from ethics and morals Prof Florence's book raises numerous other questions of the utmost importance, discussion of which is pre cluded by lack of space

Sterilisation as a Practical Eugenic Policy

Sterilisation for Human Betterment a Summary of Results of 6000 Operations in California, 1909–1929 By E S Gosney and Dr Paul Popenoe (A Publication of the Human Betterment Foundation) Pp xviii + 202 (New York The Macmillan Co, 1929) 8*s* 6*d* net

THIS little book is a storehouse of information on the efforts which have been made in the United States to improve the human stock by sterilising the feeble minded and the insane It appears that although *more Americano* laws have been passed in about twenty states of the Union

providing for the legal sterilisation of sexual perverts, and imbecile and insane patients in public institutions, these laws have been put into practical operation only in the State of California, so that in the book discussion is mainly concerned with the results obtained in that State

The justification for these attempts to aid Nature in eliminating the unfit is set forth in the introduction Amongst our unsentimental forefathers, no efforts were made to keep alive weakly and diseased children, and hence the race was propagated only from its most vigorous members, but nowadays, when unreflecting humanitarian sentiment is in fashion, all babies are kept alive so far as medical science can avail, and this science is paid for by levying tribute on the thrifty and self supporting The result is that this section of society limits its offspring, and future generations are likely to be recruited not from the fit but from the unfit

How drastically and efficiently natural selection operated amongst the young in England during the eighteenth century may be gathered from figures given by Miss Buer in her book, "Health, Wealth, and Population in the Early Days of the Industrial Revolution" In 1730, out of all babies born in London, 74 per cent died before they were five years of age, in 1750, 63 per cent died, in 1770 the percentage was 50, and it did not sink to 30 until 1833 The percentage was probably even higher in other parts of the country The help given by hospitals, and later by the State, to indigent mothers has all grown up in the last century, so that the argument that because we have maintained a vigorous, enterprising, fighting race in these islands for eight hundred years since the Norman Conquest, we shall continue to do so, is not one for which there is any sound basis

It is, however, not practical politics to suggest a return to the old plan of *laissez faire* How then shall the elimination of the unfit be promoted? The authors of this book suggest 'by legalised sterilisation' The method of sterilisation advocated is cutting the ducts (vasa deferentia in the male, and Fallopian tubes in the female) which convey the germ cells to the exterior The authors point out that more than six thousand operations of this sort have been already performed in California, and that only seven failures are recorded (three in males, four in females) The operation does not interfere with sexual desire or the performance of the sexual act The genital organs in man, as in Vertebrata generally, have two functions, namely. (1) to produce the germ cells, (2) to produce a hormone which diffuses through the system and maintains youth and vigour In a man the spermatozoa forms a minor part of the sexual discharge, the main portion of which is constituted by the prostatic secretion, and some authorities hold that this secretion when absorbed by the female has an invigorating effect on the constitution As to a woman, when it becomes necessary on account of tumours to remove the uterus, if a portion of one of the ovaries is preserved and sewn to the abdominal wall, this will prevent the premature onset of the menopause and maintain in the patient all the qualities of a young woman

But are insanity and mental defect hereditary? Some British authorities hold that in many cases they are not So far as insanity is concerned, however, there is general agreement, as our authors point out, that the condition known as 'dementia praecox' is the result of an inborn weakened constitution, and that it is a mere question of time when it will manifest itself in the life of the unfortunate individual who has inherited this constitution As to mental defect, the argument that it is sometimes not of hereditary origin, overlooks the consideration that all 'mutations', of which mental defect is one, must ultimately have been produced by some external cause, and there is nothing to show that an 'accidental' mental defective will not propagate mentally defective children In any event, even if a defective should produce healthy children, such a person would make the worst possible parent to carry out the duty of caring for and training the children, and it is a little too much to ask the State to allow a defective to go on having children on the chance of some of them being normal, if the State has to support them all

Our authors urge that sterilisation should not be regarded as a punishment but as a hygienic measure, that defectives confined in asylums might be allowed out on condition of their consenting to this operation But whilst we agree that this argument is good so far as it goes, a little reflection will show that it only touches the fringe of the problem The defectives most dangerous to society are those who are never confined in institutions at all! The high grade defectives are just able to support themselves in the lowest paid and most unskilled occupations, and no civilised government would take the responsibility of confining them, and so they go on propagating large families as stupid as themselves As Mr Lidbetter has shown,[1] it is from the ranks of just these classes that in the

[1] "Pauperism and Heredity", by E J Lidbetter, *The Eugenics Review*, vol. 14, p 152, 1923

last hundred years the majority of paupers and criminals of London has been recruited

It seems to us that in the last resort compulsory sterilisation will have to be inflicted as a penalty for the economic sin of producing more children than the parents can support Whether a man has a large or a small family is—given a healthy wife—a matter of taste, so long as he provides for his own children, but when he comes to the State and demands that it—that is to say, his neighbours—should support these children, then the State can say, "Very well—we shall help you with the family which you have, but if after this you have any more children you shall be sterilised"

Before, however, such an alternative is presented to any citizen, he may justly claim that he should receive instruction from the State in the means of birth control It is obviously unfair that such knowledge should be denied to the poor whilst it is easily accessible to the rich It is often said, and with justice, that the great objection to birth control is that the wrong people practise it But this knowledge once attained cannot be taken away, the middle classes possess it and cannot be prevented from putting it into practice If, however, the knowledge and practice of birth control were widely spread among the working class, there would be created such a resentment against the reckless production of children that the movement to establish compulsory sterilisation of the unfit would prove irresistible E W MACBRIDE

Index Londinensis

Index Londinensis to Illustrations of Flowering Plants, Ferns and Fern Allies being an emended and enlarged edition continued up to the end of the Year 1920 of Pritzel's Alphabetical Register of Representations of Flowering Plants and Ferns compiled from Botanical and Horticultural Publications of the XVIIIth and XIXth Centuries Prepared under the Auspices of the Royal Horticultural Society of London at the Royal Botanic Gardens, Kew, by O Stapf Vol 1 Pp xx + 547 (Oxford Clarendon Press, London Oxford University Press, 1929) 105s net

IN 1855 Dr G A Pritzel, who was keeper of the Royal Library at Berlin, brought out his well-known work, the "Iconum Botanicarum Index locupletissmus", being what was then regarded as an exhaustive register of all known illustrations of Phanerogams and Vascular Cryptogams, chiefly from the time of Linnæus onwards

The botanical and horticultural worlds are now able to welcome (what has been long overdue) the publication of the first volume of an emended and enlarged edition of Pritzel's work, under the title of "Index Londinensis to Illustrations of Flowering Plants, Ferns and Fern Allies" The editor of this important work is Dr Otto Stapf

About twenty years ago, the necessity of preparing a new edition of 'Pritzel' became not only obvious, but also urgent The council of the Royal Horticultural Society and Sir David Prain, the then director of the Royal Gardens, Kew, made an unsuccessful appeal for the necessary funds However, in 1912 the sum of £250 from the profits of the International Horticultural Exhibition at Chelsea formed the nucleus of a fund which made possible the commencement of the work About the year 1917 the Royal Horticultural Society began the task of organising the big undertaking which a revision of 'Pritzel' would naturally entail, and guaranteed the cost of the compilation, and at the same time received grateful help from contributors interested in the work Two committees were constituted to draw up a code of recommendations, as a result of which an honorary editor was appointed, and the work was started in July 1918 at the Herbarium of the Royal Gardens, Kew, where the director granted the use of a room and placed the resources of the library at the disposal of the staff

By the summer of 1927 a prospectus and proof page of the new 'Index' were issued At the same time, negotiations were carried on with the delegates of the Clarendon Press, Oxford, for the printing of the work In the summer of 1928, the card manuscript of the first volume, comprising nearly 84,000 references to illustrations in various books and periodicals from all over the world, was in the hands of the printers When the remaining five volumes are published, the total number of entries will amount to nearly half a million

As there were about 107,000 references in Pritzel's old 'Index', the additional 380,000 consists of those which were omitted by him and, added to these, the references to the pictorial literature published since 1865, the date of issue of the supplement to 'Pritzel' This will give some idea of the great scope of the work The references are from all publications of post Linnæan date, that is, from 1753, and extend so far as the year 1920 inclusive (For example, there are 153 references to illustrations of the common daisy) However, owing to the high quality of the pictures in certain books of pre Linnæan date, such as Rumphius's "Herbarium Amboinense" (1741) and Rheede's

"Hortus Malabaricus" (1686), these have been taken up, but not without the aid of certain modern commentaries on those works

The citations in the new 'Index' are of illustrations of Phanerogams, ferns and fern allies, the lower Cryptogams being excluded They represent 'portraits' of plants showing the habit, and of detached portions of a plant, and of such details as help to indicate the morphology of the various parts But anatomical structures and fossil plants are excluded Although teratological forms ('sports', 'monstrosities') are not, as a rule, admitted, they nevertheless very frequently occur, as no sharp line can possibly be drawn between normal and abnormal structures

No distinction is made between illustrations of species, subspecies, varieties, or hybrids, so long as they are accompanied by scientific names, and figures having only a generic name are not admitted Not more than four names (including the generic one) are used, for example, *Acer pseudoplatanus quinquelobum clausum* The spelling of plant names is in accord with the Latin as taught in modern schools, but *uniformity* is sought throughout, for example, of the two forms 'ceylanica' and 'zeylanica', the former is always used, but the latter is given in a cross reference The authors of plant names have been quoted throughout, but absolute exactitude in all cases cannot be guaranteed, especially as regards the authors of varietal names! Certain symbols are used, for example, an asterisk (*) to denote a picture wholly, or in part, coloured, a note of exclamation (!) to signify a 'sport', and (×) for a hybrid The sequence is alphabetical for the generic and specific names and the minor grades, but is chronological for the references In the matter of cross references, it should be said in the first place that, as regards species, the names under illustrations are simply registered as they are found, no attempt being made to correct inaccuracies when such occur, except when they are obviously due to inadvertent slips

When, however, as sometimes happens, these names are at variance with those which occur in the text, this fact is mentioned in the reference, and cross references are introduced under the respective quotations As regards *genera*, species are often put under generic names with which they have long ceased to be connected, a system of cross referencing has therefore been devised, based on Dalla Torre and Harms' "Genera Siphonogamarum" (1900–7), or, where this is out of-date, on modern monographs or the editor's personal knowledge

The preface, by the president of the Royal Horticultural Society, is in English and Latin The editor's introduction, giving a brief sketch of Pritzel's life and an account of the scope of the whole work, is in English only The key to the use of the 'Index', on account of its great importance, has been printed in English, French, and German This is followed by a list of subscribers

Vol 1 consists of 547 quarto pages and contains references to illustrations from *Aa* to *Campanopsis*, the letter *C* being thus split up between Vols 1 and 2 Five more volumes will appear in due course The price of the work is £5 5*s* per volume

No one who has not been actually engaged in the task can adequately realise the enormous amount of work and thought which the production of the manuscript of the 'Index' entails The delegates to the Clarendon Press are to be congratulated on the admirable way in which it is being printed While the 'Index' will scarcely be as useful to gardeners as would seem to have been at first surmised by its promoters, it will be of undoubted utility to the editors of gardening journals, to universities, and in botanical libraries like those at Kew and South Kensington

If, henceforward, the student in botany or horticulture finds the task of turning up pictures of any particular plant or plants immensely easier than he ever did before, it will be due to the facilities provided by the "Index Londinensis"

Physiological Mechanics of Piano-playing

The Physiological Mechanics of Piano Technique an Experimental Study of the Nature of Muscular Action as used in Piano playing, and of the Effects thereof upon the Piano Key and the Piano Tone By Otto Ortmann (The International Library of Music) Pp xv + 395 + 49 plates (London Kegan Paul and Co, Ltd, New York E P Dutton and Co, Inc, 1929) 21*s* net

As a treatment of the physiological mechanics of the particular motions used in piano-playing, the present volume is of intrinsic interest to comparatively few scientific workers It is of much wider interest as an example of research involving more than one of the sciences The difficulties of such research due to the ever increasing specialisation of research workers are frequently emphasised The intensive cultivation of so many small branches of the separate sciences has, however, the compensating advantage that in each the technique is so fully developed that, for

example, the mathematical physicist may well find, as did Einstein, a special mathematics ready for his application, whilst the physiologist finds that the developments of telephony provide him with electrical instruments of remarkable sensitiveness The fundamental difficulty lies in getting in touch with the required developments of the unfamiliar science, and appears to indicate not only the increasing importance of adequate indexing and abstracting of scientific literature, but also the desirability of definite training of research workers in library technique

A good example is provided by this book One would not at first associate piano playing with industrial fatigue problems, and yet Report No 14 of the Industrial Fatigue Research Board deals with "Time and Motion Study", and from its detailed bibliography we soon find that even in 1915 an elegant method had already been devised to study the motions made by workers in factories A tiny electric lamp attached to the moving limb is photographed stereoscopically to give a three dimensional record of the *path*, the light is flashed on and off again rapidly at regular intervals to indicate the *speed* of motion along the path, and the constants of the circuit are adjusted to increase the difference in the rate of brightening and dulling of the lamp filament so as to indicate the *direction* of motion It is disappointing, therefore, to find that the author of the work under notice uses merely ordinary photography of a continuously illuminated lamp attached to the pianist's hand Numerous records reproduced in the book might otherwise have yielded quantitative data There is no section on motion study in the extensive eight page bibliography

The difficulties of obtaining quantitative data on the actual muscular motion are very much greater As is clearly explained in the text, one part of a large irregularly shaped muscle may under some conditions give obvious external changes of shape, whilst another part gives no such measurable change From this it follows that precise deductions upon the movement of the whole muscle cannot be formed from observations with any apparatus which makes contact with such a muscle at a selected small part of its surface When, in addition, the contacting apparatus involves the use of the old tambour device (p 106), the results are still more unsatisfactory, and it is well to emphasise that many of the displacement-time records reproduced in the book are more qualitative than quantitative

It is stated in the preface that the experimental work has occupied five years, and that a considerable part of the time has been devoted to improvements in methods of recording There is but little quantitative data given on the new methods, and the statement on p 185 is surely a confession that the dynamograph was not always suited to the work Whilst many interesting qualitative results are given, they are almost all to be found scattered elsewhere in the writings of pianists, and the value of the research would have been very considerably increased if the author, realising that his experiments were purely physical, had taken full advantage of superior methods of measuring already available to the physicist

The avoidance of references in the text to similar work by others is undesirable in a non pedagogic scientific book, tending as it does to give a false impression of newness to the contents There is an excellent subject index, but no author index

W H GEORGE

Our Bookshelf

Experimental Building Science By J Leask Manson and Francis E Drury Vol 2 *Being an Introduction to Mechanics and its Application in the Design and Erection of Buildings* (The Cambridge Technical Series) Pp xiii + 468 (Cambridge At the University Press, 1929) 18*s* net

FOLLOWING the first volume under the same title, which dealt with the application of general elementary science to building work, the authors in this work have proceeded to develop the principles of mechanics relevant to the subject, including elasticity and strength of materials, and have applied them to the commoner forms of building construction, in such a way as to make their presentation practical and easily intelligible, without too much academic treatment The volume is in three sections The first describes the general principles governing the equilibrium of systems of forces and their application to framed structures, incidentally making reference to certain types of building plant which involve a consideration of forces in more than one plane Section 2 is mainly concerned with the theoretical aspects of elastic bending in loaded beams, and Section 3 consists of a series of chapters devoted to a practical consideration of the foregoing principles in actual work

It will be seen that the ground covered is largely the same as that in other text-books, though not necessarily in a single volume, and the advantage in the present case is that the builder and the student of building construction are provided with a manual containing, in addition to the normal traditional matter of the subject, discussions of certain important problems which are perhaps more commonly associated with the province of structural engineering, though the boundary between

the two departments is difficult enough to define Reinforced concrete thus comes in for an appreciable and appropriate amount of attention The calculation of stresses in the framed members of buildings, in which this composite material takes a leading place, it must be admitted, is now a very essential part of a knowledge of present day building construction

The treatment of the various subjects is lucid and systematic, the figures clear, and the type all that can be desired There is a serviceable index and a number of test problems with answers

B C

Life and Work in Prehistoric Times By Prof G Renard Translated by R T Clark (The History of Civilisation Series) Pp viii + 228 + 9 plates (London Kegan Paul and Co , Ltd , New York Alfred A Knopf, 1929) 12*s* 6*d* net

IT is some time since any work has appeared in English which has attempted a reconstruction of prehistoric times on the scale of M Renard's work In fact, to find anything of analogous character approaching it in completeness, we must go back to the work of Lord Avebury British writers, in dealing with prehistory, however comprehensive their scope, have as a rule confined themselves for the most part to the more or less direct evidence of archæology and the relevant elements in geology and palæontology, referring to the customs of modern primitives sparingly for illustration and elucidation only M Renard attempts a more synthetic treatment and draws largely on the data of ethnology and ethnography He treats of both material culture and social organisation In regard to the former, a more precise documentation would have been an advantage in many cases For example, in the generalised account of the origin of cultivated plants, it would have added to the value for the reader for whom a book of this type was intended had the evidence for the probable origin of cultivated plants been cited more precisely The same applies to domesticated animals, especially the dog and horse In his account both of art and of personal adornment and clothing, M Renard gives less weight to the influence of religion and magic than most archæologists and ethnologists would be prepared to allow It is difficult to admit that tattooing, for example, is, either in origin or in practice, purely a matter of personal adornment

The Practice of Spectrum Analysis with Hilger Instruments including a Note on the various Types of Emission Spectra Compiled by F Twyman Fourth edition Contributors Prof E N da C Andrade, Dr Samuel Judd Lewis, D M Smith, S Barratt, A A Fitch, J W Ryde Pp 39 (London Adam Hilger, Ltd , 1929) 1*s* 6*d* net

As the title suggests, this is a practical handbook, giving in detail the experimental procedure to be followed in the solution of various academic and industrial problems The usual arc and spark methods receive full notice with numerous references to possible difficulties, for example, confusion by adjacent lines , it is shown how these may be avoided in ordinary practice The exploded wire method for fine wires or filaments is described at length, showing, for example, how 0 2 per cent of thorium in a tungsten filament may be not only detected, but also determined, when the piece available is only 1 5 cm long and weighs one fifth of a milligram The application of the recently introduced 'R U Powder' (Raies Ultimes) prepared so as to give under suitable conditions a composite spectrum exhibiting a small number, usually about seven, of the most persistent lines of about fifty elements, is demonstrated in the text and by photographs The purpose is to identify the chief lines of all the elements in a sample by producing its spectrogram in juxtaposition with that of a portion of the R U powder Useful information is given on quantitative spectrum analysis as conducted without resort to special equipment

The chapter on the various types of spectrum discusses the theoretical bases on which the practical processes are formulated, and will be found both helpful and suggestive in the laboratory

Engineering for Masonry Dams By William Pitcher Creager Second edition Pp xiv + 294 (New York John Wiley and Sons, Inc , London Chapman and Hall, Ltd , 1929) 20*s* net

THE second edition of this text book on masonry dams is a revision to date of the earlier volume (which was reviewed in NATURE of June 20, 1918, p 301), with the deletion of certain obsolete matter and the inclusion of new data and information, making a net enlargement of 57 pages The chapter on details and accessories, in particular, has been extended so as to include a fuller description of outlet control and floodgates A quantity of relevant material has been incorporated which is included in the hydro electric handbook, by the same author jointly with Mr Justin, published in 1927

The book is, of course, mainly a reflection of American practice, and in view of the attention which is being given on the western side of the Atlantic to the development of water power and the impounding of water supplies for this and other purposes, the experience obtained and recorded in the volume is of no little interest and value to water engineers

B C

The Purple Land being the Narrative of one Richard Lamb's Adventures in the Banda Oriental, in South America, as told by Himself By W H Hudson Pp 368 + 13 plates (London Gerald Duckworth and Co , Ltd , 1929) 15*s* net.

IMAGINE Don Quixote with a dash of Scottish caution, and we have the beloved naturalist in his youth His main concern is with the pretty girls of Uruguay, and his treatise should prove irresistible to all young biologists Other scientific themes are carefully avoided, but there is all the fun of a comic revolution, which is tragic enough to draw tears—both sides of humour It is a grand book, by one of the heroes of science

Anent Metameric Hydrogens

AT the recent anniversary meeting of the Royal Society, Sir Oliver Lodge, with his accustomed charming perspicacity, in moving the vote of thanks to the president, referred to the happy way in which he endeavours to interpret to the old fogies the mystic feats of the juvenals who now soar into mathematical physical empyreans not only beyond the reach but also beyond the comprehension of us weak ordinary mortals Well might the Primate remark at the anniversary dinner that "the relations of religion and science have never been more cordial" This is so—not because the clerics are being made wise by 'science' but because its reputed followers are more and more walking in the clerical train and tending to write superstition for science Nothing could be further from the truth than the Archbishop's reported statement—"that both religion and science had given up the bad habit of being dogmatic" The mistake comes from the fact that, on both sides, the language used is so mystical that no one knows what it means pure hyperbole is current in both camps If coming together, it is because the body scientific is more and more being given over to dogma, doctrine and fashion, fast losing the sense of modesty and disregarding the Pauline mandate to—Prove all things!

The president, this year, has dwelt upon the picture the younger wiselings are drawing of the jinks and jazz indulged in, 'they guess', by molecules so simple and staid as we have thought those of hydrogen to be Granted the existence of two metameric forms of so primitive a molecule, attention may be directed to what *is* surprising (not the existence of varieties of the gas)—the observed prolonged stability of the one form and the influence of charcoal in effecting its rapid transformation Apparently, the change from one form into the other is no mere temperature nor time effect Physicists are apt to pay no attention to the process of change—they seem to have thermodynamic minds theirs not to reason how If the physicist have a living soul, it is one that lacks the sense of purity, he could never have paid so much attention to impure materials had he had one Electricity just passes through a gas, electrons are supposed to have no truck of convoy The evidence that chemical change only takes place in a tripartite conducting circuit is not considered, at most it is airily dismissed with a summary reference to ions—the pink silk stockings worn to day throughout the 'scientific' community—which not only can do no wrong but also are rated capable of anything and everything

A great number of instances of metameric change are known to us One of the most fundamental is that of acetoacetic ether, a compound existing in two isodynamic forms, one a keto form containing the radicle CH_2 CO , the other an enol form containing the isomeric group CH C(OH) In a highly purified state, these change so slowly that it is rational to assume that they would not change if *pure* an inconceivable worldly condition The passage from one into the other undoubtedly takes place under the influence of an *electrolytic determinant*, whereby CO becomes CX(OH) and X then walks away with an H from the contiguous CH_2—or vice versa I venture to assert this and deny that mere kinetic collision can 'do the trick'

It has long been an article of faith in my religion, that spectral lines, and now even the assumed orbital shifts in electron levels, are consequences of this order of process Like Joan of Arc, I at times am told by 'my voices' The process I contemplate is a sort of a kind of incarnation—mayhap resembling that of which Sir Oliver Lodge dreams As he would say 'I don't know' That one form of hydrogen should pass into the other when brought into contact with charcoal might, I suggest, be due to an electrolytic determinant at its surface The condensation of a gas at the surface of charcoal is undoubtedly a chemical process, one to which arguments may be applied similar to those used by Aitkon and others with reference to the formation of Water (rain drops) from hydrone The existence of two forms of hydrogen in equilibrium makes no greater call upon my imagination than does the passage of water into ice being so familiar with the fact, we in no way regard the expansion as remarkable Surely, there must be some great change in fundamental molecular contexture Water, unfortunately, has no power to day to soothe the subsidised breast of the modern researcher we are only worried by it, if it come through our roof and the valleys are flooded as it is so prone to function in waves, perhaps wave mechanicians will some day deign to notice it

We have long been aware that elementary molecules are not always fixed structures In this connexion, Sir James Dewar's remarkable but little regarded observations upon the sudden change in the specific heats of many metals at liquid hydrogen temperatures are specially noteworthy Whilst the so called atomic heat (sp ht × at wt) is almost a constant at ordinary levels, the values vary periodically at very low temperatures The alkali metals alone seem to preserve their equanimity I have always thought of such changes in elementary materials as evidence of the existence of metameric forms

Sir Ernest Rutherford speaks of a "very weak coupling" between the two states of hydrogen He also talks mysteriously of symmetrical and antisymmetrical orbital wave functions That so great a master of the art of simple expression should speak in terms so meaningless to most of us, I suppose comes from the fact that the language of wave mechanics cannot be translated down to our level It cannot be that he has joined camp with the *Jargonotropists*, protonotropist though he be When we are sufficiently quantised to be hypnotised by such terms, doubtless we shall all be worshippers of the new faith We need, however, a little more instruction before confirmation—it is difficult to recite a catechism in terms of an unknown tongue

Here the question is perhaps pertinent—Have we a known tongue to day? I notice that the heading to Sir Ernest's address is "Recent Reactions between Theory and Experiment" Should we not read guess or speculation for theory? Is not theory a sacred word, of sublime import, to be used only on royal occasions? In NATURE I fear it is almost systematically put to vulgar use—even by the great Prof Eddington, a master in the art of expression, in the issue of Nov 30, speaks of proposing "a theory" of electronic charge—which is so little a theory that he gets a value of 136 one week and 137 another Remembering him as I do, as a most active member of the Astronomical Corps de Ballet that entertained us in 1914 on the way out to Australia, I can see him gaily dancing through the scale of numbers and giving us other values in weeks to come I have been brought up to regard a theory

as a body of established doctrine, not a shifting guesswork In the same number of NATURE, in the review on the "Origin of Coral Reefs", the word is systematically perverted—it almost always is I go among schoolmasters advocating scientific method How am I to hold up my head when, in using words, my tribe is so careless? We weigh things to the *n*th decimal—but rarely our words Cannot we do something by way of example, so that our youth may not always babel on'? We have yet to learn to serve up our dish of science with proper trimmings

Even the word 'science' has no established meaning In the introduction to his recently published all comprehensive "History of Science", Mr W C D Dampier Whetham tells us that the English word science is used as a shortened term for natural science, though the nearest German equivalent, *Wissenschaft*, still includes all systematic study Surely, this is wrong 'Science' *is* 'the business of knowing', the production of knowledge, truth of whatever kind What some of us are trying to do is to exclude from it unnatural knowledge as was the desire of the early founders of the Royal Society

HENRY E ARMSTRONG

Early Rhodesian Gold

THE preliminary report by Miss Caton Thompson and the letter from Prof J W Gregory (NATURE, Nov 9) are of great interest to students of history It is well to bring forward the contradictory evidence, as Prof Gregory has done In regard to the estimate of a gold production, in ancient or medieval days, amounting to £75,000,000, I venture to express a warning The production and disposal of any such quantity of gold would have made a big stir at any time in the world's history Its commercial value in medieval days, or earlier, would be, at least, twenty times its present value, and an addition of the equivalent of £1,500,000,000 to the world's wealth would be a great event, would it not? We have no whisper in historical records of any such contribution coming from the gold mines of any region before the Californian and Australian discoveries The Spaniards obtained most of their South American gold from the graves, not the mines, of Peru, Colombia, and Venezuela Again, £75,000,000 in gold represents a weight of 625 tons

As a mining engineer, informed concerning the Rhodesian mines, I beg to submit that the estimates made by Edwards, Hammond, or others should not be accepted by archæologists, because they were made at a time when the Rhodesian diggings were being boomed on the London stock exchange Such estimates have no value for the historian The removal of 100,000,000 tons means the excavating of a vast number of cubic feet of rock, Where is the evidence of such extensive work?

As to the ingot found in Falmouth harbour, we have no evidence as to its Phœnician origin, the statement by Diodorus concerning the *astragalos*, or knuckle bone, pattern has nothing to do with the Phœnicians, he is referring to the tin trade of his own day, that is, about 25 B C, when the tin was carried overland from Corbilo, at the mouth of the Loire, to Massilia, at the mouth of the Rhone I have examined the Falmouth relic and I have seen a soapstone mould of a supposedly same type in the Bulawayo museum They have nothing in common The Falmouth ingot has a shape evidently suited for convenience in packing on horseback across Gaul We have no proof that the Phœnicians mined Cornish tin or went thither to obtain it, on the contrary, the evidence suggests that they traded with the Veneti, or their predecessors, at the mouth of the Loire, where, in Morbihan, they themselves mined for tin, and probably also traded with the Britons, meeting them on the island of Ictis as described by Diodorus The supposed identity of ingot moulds is to be taken no more seriously than the idea that phallic emblems necessarily signify Phœnician operations at Zimbabwe

T A RICKARD

Faculty Club,
University of California,
Nov 25, 1929

DR RICKARD's letter carries the weight of his high authority on early mining Yet the estimates of the great gold output from Rhodesia were not made on the London Stock Exchange, but by responsible mining engineers who were well acquainted with the ancient workings When discussing Telford Edward's estimate with the local authorities in 1905, they expressed the view that his figure would have to be increased owing to the discovery of many additional workings In view of the size and number of the ancient mines, I felt that the excavation from them of 100 million tons was not exaggerated The workings are direct evidence of an output of gold which as Dr Rickard says, would have made a stir in the world The discoveries at Ur and in Egypt show that the people of those countries had tons and tons of gold If the Rhodesian gold mining had been medieval, we should surely have evidence of it in the gold or by tradition

In view of the suggestion that the gold was mined in connexion with the Arab settlement of the East African coast, I recently asked Sir Robert Hamilton whether he knew of any evidence of the Arabs there having had any large quantities of gold He replied "I have seen and myself collected a few gold and gold inlaid ornaments on the coast, some, the majority, were obviously not very old, being made out of sovereigns, others were older, those mostly from Lamu and Patta, which generally appeared to be of Persian origin or design In any case the amount was trifling On the other hand, old swords and daggers which are often treasured possessions, are generally hilted and adorned with silver work of Arab origin While there are traditions of wealth in ivory and slaves I have never come across traditions of wealth in gold or of trading in gold, and so far as my reading of history goes I do not recollect any recorded accounts of the early European discoverers and explorers on the E coast finding the Arabs in possession of wealth in the shape of gold nuggets, dust, or ornaments The evidence is naturally defective and negative, but I should hesitate to believe that the medieval coast Arabs possessed gold in any quantity without a great deal more positive and convincing evidence than I have yet seen"

In reference to the Falmouth tin ingot, the stamp on it has been described as the mark of a Phœnician or Greek trader The ingot was accepted as Phœnician by the best opinion of the time of its description by Sir Henry James, for Lord Leighton, who was careful to obtain the best expert advice, pictured it in his fresco in the Royal Exchange of the Phœnicians trading with the ancient Britons Dr Rickard remarks that this ingot and the Zimbabwe ingot-moulds have nothing in common Their similar shape seemed to me so significant that I published outline drawings of them, to show their resemblance, in *Trans Inst Min Eng*, vol 31, 1905–6, Pl I Figs 2 and 3 The loss of the ingot near the entrance to Falmouth Harbour was attributed by Sir Henry James to the boat having been wrecked while seeking shelter there "on its voyage coastways to Boulogne"

Some of the tin for Phœnicia may have been carried across Gaul to Marseilles from the mouth of the Loire, but the use of the Boulogne route for the Cornish tin has been generally accepted

J W GREGORY

Glasgow, C 3

The Product of the Radioactive Disintegration of Potassium

IT has been shown by numerous investigators that potassium and salts of potassium are radioactive, the activity being due to the emission of β particles by the atoms of potassium In accordance with the radioactive displacement law, Hahn and Rothenbach (*Phys Zeit*, 20, p 194, 1919) pointed out that this β-transformation of potassium should result in the production of an isotope of calcium, without change in atomic weight On the other hand, S Rosseland (*Zeit f Phys*, 14, p 173, 1923) has put forward an ingenious suggestion which does not necessitate the production of a calcium isotope Later, Hevesy and Løgstrup (*Zeit anorg Chem*, 171, p 1, 1928) showed experimentally that the radioactivity of potassium appears to be confined to the isotope of mass 41, Aston had previously shown that potassium consists of two isotopes of masses 39 and 41 If only the isotope of mass 41 is radioactive, Holmes and Lawson (*Phil Mag*, 2, p 1218, 1926) worked out the half value period of this isotope, and on the basis of this result, Hevesy and Løgstrup calculated that, if we assume the earth to have existed for 10^9 years, about 0 001 of all the potassium in the earth must have been trans formed into calcium of atomic weight 41

As a result of an examination carried out by one of us on a series of samples of microcline from Miask (Urals), a variety has been found containing 11 per cent of potassium and only 0 042 per cent of calcium In accordance with the calculations of Hevesy and Løgstrup, there should be present in this mineral about 0 01 per cent of Ca^{41}, which has been generated from potassium during the life of the mineral, assumed to be 10^9 years If the remainder of the calcium (0 03 per cent) were present in the mineral during its formation, and if it had the atomic weight of ordinary calcium (40 07), we have calculated that the total calcium in the above mineral should have an intermediate combining weight of 40 30

Through the kindness of Mr Smolianinoff, director of the Mineralogical Museum of the First Moscow State University, we have been able to obtain a quantity of this mineral microcline, from which 0 15 gm of CaO was extracted After careful purification by repeated precipitation as $CaSO_4$ and CaC_2O_4, in quartz vessels and using carefully purified reagents, the atomic weight of the resulting calcium was determined by evaluation of the ratio $CaCl_2$ $CaBr_2$, the weighings being accurate to 0 01 mgm Two determinations yielded concordant results, 40 21 and 40 24, as compared with the calculated value of 40 30 The slight discrepancy can be explained by the loss of part of the calcium during its long sojourn in the earth's crust

In order to examine the accuracy of this method of determining the atomic weight and the efficiency of the method of purification, ordinary calcium (Merck's 'calcium carbonate') was mixed with salts of barium, strontium, magnesium, aluminium, and iron, and then extracted and purified by the same methods as had been used for the calcium from the microcline The atomic weight of this calcium was then determined, and the results of three experiments gave respectively, 40 06, 40 16, and 40 08, as compared with the value 40 07 of T W Richards The mean of these three results is 40 10

It is our intention to continue this investigation, and to determine accurately the atomic weight of calcium from microcline, by using a larger quantity of the material

A V FROST
O FROST

Vasily Island,
Leningrad

WE are indebted to the Editor of NATURE for the privilege of reading the above interesting communication, which, so far as it goes, seems to indicate a calcium isotope of mass 41 as the disintegration product of potassium

In view of the uncertainty which is likely to arise from the use of so small a quantity of material (0 15 gm CaO), and the rather large difference (0 1 unit) between the extreme values of their three determinations with ordinary calcium, we shall look forward with interest to the results of the authors' projected work with larger quantities of material

The suggested explanation of the discrepancy between the experimental and calculated atomic weights of calcium from microcline would surely tend to make the experimental value higher instead of lower than the calculated value It would be predominantly 40 07 calcium that would be involved if calcium were lost during the life of the mineral

The calculated value of the atomic weight of the calcium from microcline is necessarily far from trust worthy, as it involves not only the uncertainty of the disintegration constant of potassium, but also an undoubted error in the age assigned to the microcline According to Backlund, the pegmatites of Miask are younger than the biotite granite of the region and the cataclastic deformation that followed that is to say, they are a little younger than the orogenesis of Artinskian (Lower Permian) time Stratigraphically they are directly known to be younger than the Middle Carboniferous As von Bubnoff has pointed out, sedimentary deposits younger than the Middle Carboniferous are not known in the East Urals, and exact time definition is therefore not practicable

It is nevertheless clear that the age to be considered in making the atomic weight calculation should be not 10^9 years, but rather less than 2×10^8 years Adopting the latter figure, the amount of Ca^{41} in the extracted calcium from the microcline would be only 5 per cent as against 25 per cent previously assumed It is here tacitly assumed that the average atomic weight of ordinary calcium was the same 2×10^8 years ago as it is now There is no means of estimating the difference, but as it is in any case quite inappreciable, it may safely be ignored For an age 2×10^8 years the atomic weight of the microcline calcium is calculated to be almost exactly 40 1

ARTHUR HOLMES
ROBERT W LAWSON

Measurements of Noise by Means of a Tuning-fork.

IN recent work I have been assessing the loudness of certain noises by means of an audiometer of the type in which a note in a telephone earpiece over one ear is adjusted in loudness until it appears to be as loud as the noise observed by the other ear, or alternatively, is just masked by it For general observations of everyday noise when the instrument is not at hand, I find it possible to use a tuning fork on the same lines The fork is struck in a standard manner, and note is made of the time which elapses before the loudness of the fork, when placed as close to the ear as possible with the flat of a prong facing the auditory meatus, falls to the loudness of the observed noise

The total interval which elapses before the fork is masked by the noise is also taken for check purposes.

Since the sensation stimulus law of the ear and the law of decay of the fork vibrations are both practically logarithmic, it follows that equal intervals of time give approximately equal reductions in the loudness of the note from a struck fork. The fork actually used had a frequency of 640 vibrations per second. The intensity of the note when the fork was first struck was about 90 decibels[1] above the threshold and it died away to inaudibility in about 62 seconds. The average rate of decay was thus about 1½ decibels per second. Actually it was found that the decay of the fork was rather greater at large amplitudes than at small—a fact that may be associated with an observed drift in the performance of the fork during the months it has been in use. Since it was known that the pressure variation in the minimum sound of this pitch audible to the observer's ear was about 1 millidyne per sq. cm., the scale of the loudness of the fork is an absolute one.

By extrapolating an approximately average linear relation found to exist for moderately loud noises between 'equality' results and 'masking' values, it was possible to use 'masking' values alone in assessing noises which were louder than the fork, and the scale was thus extended to 110 decibels above the threshold.

A number of observations of the ordinary level of daily noise taken over a period of some months have been summarised in the table. It is not claimed that the table is complete, or that conditions were always average, but consistency and reasonableness were revealed when observations made over a period of some months were summarised. For example, an accelerating bus gave the same result when observed in Regent Street as when observed on a quiet night in Teddington. A really busy street was practically as noisy at Kingston as near Oxford Circus in London, and had the general loudness of accelerating cars and buses. Experiments in the first and third class compartments of a certain train revealed that the noise levels were about the same until the windows were closed, and then the first class compartment was definitely the quieter by some 5 decibels or so.

Loud radio speech at home corresponded with really loud conversation, and transmission through a 4½ in. brick wall into an adjacent room reduced the level by some 30 decibels to that of rather quiet conversation. In an interesting case where complaint was made of the noise from a loud speaker which could be heard up and down a residential street, the loudness observed through open windows in a room in the house on the opposite side of the street was also of conversational level. The fatigue of conversation in busy streets, trains, buses, trams, and noisy restaurants, is to be expected from the fact that the level of noise is generally greater than that of conversation.

A. H. Davis.

Physics Department,
National Physical Laboratory,
Teddington, Middlesex.

LOUDNESS LEVELS OF VARIOUS NOISES

Fork Loudness (Decibels above Threshold)	At Home	In Street	In Vehicles	Miscellaneous
130				Threshold of painful sounds
120				
110				Aero engine (10) (unsilenced)
100				Express train (12) (estimated)
90		Pneumatic drill (20)	Tram on v. noisy rails	
80	V. l. radio music	Motor horn (20)	Tube train	
70	L. radio music	V. busy traffic accelerating cars and buses	Bus top. Tram. Train (open windows)	Electric train starting. V. noisy restaurant. Typewriter
60	L. radio speech	Busy traffic	Saloon car (35 m.p.h.)	
50	Q. radio music. Conversation	Q. car. Q. street, behind Regent St.	Train (windows shut), 1st class	Moderate restaurant clatter
40	L. whisper (5). V. q. radio		Saloon car (25 m.p.h.)	Q. restaurant in Strand
30		Q. street, evening, no traffic, suburban		Walking on gravel. Rustle of leaves in wind
20	Q. garden			
10	Q. whisper (5)			

(Q = quiet. L = loud. Figures in brackets are distances in feet from the source.)

[1] A change of 1 decibel—a power step of $10^{0.1}$ fold or 1.26 fold—is of the order of the minimum difference in loudness detectable by the ear.

Thames Floods and Pollution

The note on the Thames flood of 1928 (Nature, Jan. 4, p. 32) is of the very greatest topical interest, for not only have the recent December floods covered an unexpectedly large area, again submerging districts upon which council houses have been built, but they have also shown how river pollution must rapidly increase as fields get replaced by residential quarters with drainage systems far below the level of the river.

According to the old order of Nature, flood waters used to accumulate above Oxford, perhaps submerging the water meadows for weeks at a time, but at any rate much water was there ponded, helping to save from

serious flooding more valuable lower reaches of the Thames nearer London Recent experiences seem to show that the Conservators of the Thames are changing this By costly enlargements of weirs, channels, and bridges, the water is hurried down from the upper pastures on to the residential areas below These areas, being land liable to flooding, would never have been built upon but for the optimistic parrot cry of 'No more floods', whenever some notable work of river engineering has been accomplished Either in spite of what has been done, or in consequence of it, the failures have been so frequent and so costly, that the time is ripe for a thorough and scientific investigation of very complex problems that need never have arisen The river is no longer adequate to meet all the requirements of those huge and increasing populations that have settled within its watershed It therefore becomes necessary to define the objects of primary importance that are served by the Thames, and what should be subordinated thereto

That there are good grounds for mistrust in the future is shown by a recent publication, "The Thames Valley from Cricklade to Staines", in which the urgent duty of the preservation of the beautiful and beloved 'landscape character' of the river is most strongly advocated But it behoves a scientific statesman to approach the subject from a rather different point of view

The essential of a river is not its setting, but its water London draws a large percentage of its drinking water from the Thames Oxford and Reading are equally dependent upon it The few barges and factories upon the upper reaches are surely matters of small consequence as compared with London's need of pure water Birmingham, Liverpool, Glasgow have all acquired Nature reserves as catchment basins for their water supply, and take extraordinary precautions to preserve the purity of their sources Streams that are possible sources of pollution have been diverted, dwelling houses have been pulled down, tenants have been evicted, the very hillsides have been rationed in the matter of grazing cattle The result is a city supply of a beverage that is worth drinking London has been strangely apathetic in the matter, with the result that she drinks the bath water of other towns indeed, much of her 'water' is stuff to which that blessed word 'effluent' has been applied several times over Oxford drinks the effluent of factories on the upper Thames and its tributaries, and puts effluent back into the river at Kennington for the benefit of towns below Similarly, Reading uses what it desires, and excretes an 'effluent' for others Finally, the water after final chlorination is served in the flat form familiar to the citizens of the capital city of the Empire

All through the drought of the past summer, the stagnant river had barely current enough to shift an oily scum, derived from motor boats and the washings of motor-cars This scum is most harmful to bird and animal life, and is most deterrent to picnickers During the past month the upper Thames has suffered pollution through the gushing of sewage from low lying drains into the Thames, by the washing out of gas-water from a huge gasometer into the river—and water over which coal-gas has been standing is perhaps one of the most deadly of effluents to fish life, and by the unhindered flow of inky black effluent (untreated) from the refuse dumps of Oxford directly into the Thames It is obvious that the river is also receiving water that has been slowly flowing over acres of manured allotment grounds, and through thousands of ill-kept back yards of slum houses Everything soluble, and much that can be carried in suspension, will go floating down stream to the intakes of the Water Board We admire their assiduity in sterilising and their success in preparing drinking water from such polluted sources

The real question to be settled is why precautions which are taken to preserve the purity of the water of Lake Vyrnwy or Lake Thirlmere should not be applied to the Thames The scheme of confining the river to a narrow canal would be costly, inefficient, and inexpedient, but the preservation of a natural river flowing beside a definite flood zone of water meadows, free from exceptional sources of contamination, would be Nature's own way of dealing with the needs of the Thames

An independent potamological station for the scientific investigation of the Thames has often been suggested It could perform a national service now

R T GUNTHER

Visible Electron Diffraction

UNTIL now diffraction of electrons has only been made evident by delicate electrometric measurements or by photographic exposures of several hours I have succeeded for the first time in making visible on a fluorescent screen diffraction rings produced by a crystalline powder This latter is a thin film of zinc oxide obtained according to the process described by M Ponte (*Comptes rendus*, **188**, 244, Jan 1929) This film is formed by an agglomeration of microcrystalline particles of smoke and possesses marked electrical conductivity While working the tube, one can bring a given sample or a given area of the sample into the

FIG 1 —Diffraction rings of zinc oxide
$V = 19$ k v $D = 13$ cm exposure = 10 seconds

path of the electron beam With a current of some tenths of a milliampere and a voltage exceeding 8000 volts between the cathode and the collimator tube, the two principal rings of zinc oxide are easily visible (Fig 1) They are some tenths of a millimetre wide and some centimetres in diameter

One can follow on the screen their variation in diameter according to the voltage The moving of a magnet near the tube displaced the entire diffraction pattern Using ordinary photographic plates, the necessary time exposure under 15 k v. pressure does not exceed ten seconds The law of M Louis de Broglie is easily verified with an approximation of a few hundredths The sight on the screen of movable rings of a variable diameter seems thus to provide the most direct and convincing proof of crystalline electron diffraction

Reflection of Protons from Calcite

I HAVE recently found that hydrogen canal rays give a complex reflection pattern when they are allowed to fall on a cleavage face of a calcite crystal at almost grazing incidence Fig 1 shows one of these patterns The crystal was placed horizontally and was held by a wire spring bearing on the top A narrow bundle of the rays struck the crystal underneath the wire, which was not in absolute contact with the crystal at the centre point Some of the canal rays passed over the surface of the crystal without hitting it and fell on the photographic plate 15 5 cm distant, giving rise to the central spot seen in the lower part of Fig 1 This spot appears white because of solarisation of the plate due to the concentrated neutral bundle

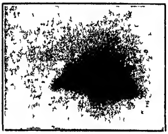

FIG 1

The upper part of the photograph shows positive particles reflected from the surface of the crystal It consists of a series of curved and straight lines forming a regular pattern which is not perfectly symmetrical about the vertical axis By increasing the angle of incidence the central spot was cut off and the figure was considerably altered The figure has a certain resemblance to the secondary lines obtained by many authors with X rays, using the rotating crystal method of analysis (Sir William Bragg, "An Introduction to Crystal Analysis", 1928, p 38), however, the angular divergence of the original bundle was scarcely large enough to give the variation in the angular deflections actually observed, and the Bragg equation gives far smaller angles than those observed if we assume an equivalent wave length from the de Broglie formula A more promising interpretation is that the lines are due to diffraction of the rays at the two dimensional gratings formed by the rows of atoms in the crystal surface With the de Broglie wave length, the angles deduced are of the right order of magnitude

FIG 2

By applying a magnetic field it was found that the whole pattern was shifted as shown in Fig 2 The arrow shows the direction of the force on a positive particle, and its length indicates the distance in the figures that subtends an angle of 0 01 radian As the blackening of a photographic plate by positive hydrogen canal rays is chiefly due to charged hydrogen atoms, we may conclude that the pattern is caused by the impact of protons The maximum potential on the discharge tube was approximately 40,000 volts, and a magnetic analysis showed that the positive ions were distributed over a considerable range of energies

Since the magnetic field does not destroy the lines, we may consider the different points as corresponding to particles of different velocities A line is thus a velocity spectrum of the protons, or, in terms of wave mechanics, a diffraction spectrum of their equivalent wave lengths It is very significant that no undeflected pattern was observed, although neutral hydrogen atoms are present in large numbers in a canal ray beam The theories of wave mechanics would not at present distinguish between the wave lengths associated with a proton and a neutral atom of the same velocity

Nature of Disease-Producing Viruses

IT has been pointed out on more than one occasion that, if filterable viruses constitute a group of ultra microscopic organisms, it is remarkable that no saprophytic forms are known In NATURE of Aug 17 last (p 267), Dr J J Davis questions the validity of this argument, at least in the present state of our knowledge "Until viruses can be known other than by the effects of their parasitism, it would seem to be quite impossible to detect corresponding bodies that are not parasitic," he says, and "until some method is devised by which the constituents of the virus can be recognised, it would seem to be useless to look for them"

In other groups of micro organisms, however, numerous forms are known, which, though normally parasitic, are yet facultative saprophytes which can be cultivated on artificial media as well as on their natural host So far, however, no one has been able to cultivate a virus on an artificial medium Re inoculation into the natural host should provide a perfectly valid test for the success of such saprophytic cultivation if it occurred There is thus a very distinct gap between the viruses and known types of living micro organisms indicated here

Again, in the case of the normally saprophytic, bacteria almost on the borders of visibility can be cultivated on solid media, forming colonies visible even to the naked eye But no colonies which might be considered those of a saprophytic virus have ever been observed on artificial media, whether on agar, gelatine, or silica gel

There are other facts which make it difficult to imagine the viruses as a group of micro organisms of somewhat the type we know in the bacteria or protozoa, only much smaller in size It would seem preferable, therefore, to keep an open mind for the present on the subject of what a virus really is, and to continue experimental work, rather than to postulate already a "hypothetical intermediate combining molecular structure, metabolism, and reproduction", and to term it a vitamol In fact it is difficult to see the distinction between *vitamol* and *virus*, and the former term is objectionable in giving a certain definiteness of ideas as to structure which our present knowledge does not warrant

Some Bands of the Carbon Molecule

THE spectrum of a condensed discharge in hydrocarbons contains, besides the well known CH and the Swan bands and some other less prominent bands, a strong system, the structure of which does not seem to have been investigated before We were able to photograph these bands in the second and partly in the fourth order of a 21 ft concave grating, and could thus resolve completely the rotational fine structure. The bands have a very strong resemblance to the Swan bands and undoubtedly arise from the same

molecule The bands investigated fit into the following scheme (wave lengths of the heads)

n' \ n''	0	1	2	3
0	*3852 1*	*4102 3*		
1	*3607 3*	*3825 6*	*4068 2*	
	3399 8	*3592 9*		*4041 9*
3		3398 1	3587 7	

The seven bands given by figures printed in italics have been investigated for fine structure Combination relations prove the correctness of the scheme

Each band consists of two P and two R branches Alternatively, the red and violet doublet components are missing This fact, which is very striking even on a rough inspection of the plates, proves that the bands must be due to a symmetrical molecule and that the nuclear spin of the atoms in question is zero There is therefore scarcely any other possibility but that the bands come from a C_2 molecule, which has also been made responsible for the Swan bands The lines are sharp and single, and our plates allow us to say with a very high degree of probability that three lines near the origin are missing The terms can be represented with great accuracy by the usual quadratic formula const $+B(j+\frac{1}{2})^2-\beta(j+\frac{1}{2})^4$ All these facts show that we have here a $^1\Pi \longrightarrow {}^1\Pi$ transition, and we believe that the electron configuration (except, of course, the orientation of the spins) is the same as that of the terms of the Swan bands

The molecular constants calculated from these bands are very near to those of the Swan bands, but they can be obtained with much greater facility and accuracy because of the simpler structure of the bands We give here the values of some of the constants It is possible that the final values, which will be calculated with the help of the complete material, will be slightly different

	B'	B''	J'	J''	ω_0'	ω_0''	ν_0
$^1\Pi \longrightarrow {}^1\Pi$	1 7732 1 7744	1 6086 1 6081	15 62	17 22	1764 9	1584 2	25969 16
$^3\Pi \longrightarrow {}^3\Pi$ (Swan bands)	1 750	1 626	15 84	17 03	1752 4	1618 1	19373 87

In this table $B=h/8\pi^2J$, J moment of inertia, ω_0 the difference between the first and the second vibrational state, and ν_0 the origin of the $0 \longrightarrow 0$ band The constant a which determines the degree of coupling of the orbital moment of momentum to the nuclear axis and therefore the 'σ doubling' is roughly $5\ 9 \times 10^3$ for the initial and $1\ 3 \times 10^4$ for the final state

Full particulars will be published elsewhere

The Muscular Sense

IN reference to the note by Prof Fraser Harris on the "Subjective Demonstration of the Existence of the Muscular Sense", in NATURE of Nov 23, I beg to point out that so far from the existence of this sense being demonstrated by the simple experiment he describes, he has really got no further than the indication of the nature of the problem William James was well acquainted with such evidences, yet he decided that the muscular sense was a "needless encumbrance" My own position is different from both, the muscular sense, or as I call it, the sense of effort, has an existence, but the affirmation of Prof Fraser Harris or the denial of William James has no particular weight, as neither is based on any analysis of a searching character.

The question is not whether a distinct sensation is perceptible in the act of raising the arm, as in the example of Prof Fraser Harris, but whether this sensation is determined by, and entirely explained by, the production of the efferent nervous stimulus necessary to activate the muscular system involved

The question of the sense of effort is one of the most elusive in the whole range of psychology, and I did not find it possible to offer a definite answer until I had completed the analysis which led to the formation of the "Fundamental Processes of the Mind" Once the meaning of these processes is grasped, such problems of psychology become susceptible of solution A complete explanation on the physical side demands a minute examination of a long series of neurological phenomena

Nothing of this is suggested by Prof Fraser Harris, while on the part of William James, though he had intuitions of the necessity of ascertaining the Fundamental Processes, he has not given us even the beginning of a valid analysis to that effect Those who are interested will find that analysis set forth with the necessary rigour in my "Principles of Psychology"

Occurrence of *Cepedea* in Frogs

WHILST examining a number of *Rana temporaria* for intestinal protozoa recently, I encountered one single frog infested with a species of *Cepedea* (Protozoa, Ciliata, Opalinidæ) So far as a survey of the available literature has revealed, the only previous record of the occurrence of a species of this genus in *R temporaria* is that of André (*Rev Suisse de la Zoologie*, vol 21, p 6, May 1913), who reports the occurrence of *Cepedea dimidiata* in frogs of this species obtained in Switzerland

The species recorded here has not yet been examined in sufficient detail to enable me to state whether it is *C dimidiata* or not, though a cursory examination has shown it to differ appreciably in size from typical *dimidiata* obtained from *Rana esculenta* Out of a large number of frogs obtained and examined either by me or in the course of class work, no others have shown the presence of this species, unfortunately, I have not been able to determine the locality from which they were obtained, apart from the statement that they were collected in England

The Secondary Split in the Maturation Divisions of Liliaceous Plants

APPROPRIATE destaining in mid pachytene has disclosed two, and only two, rows of genes, minute bodies nearly at the limit of microscopical vision Repeated observations have shown that the sets of four chromioles seen at late pachytene are united in two pairs, like two dumb bells, one on each side of the primary split Here the secondary split has not yet been completed Observations of diplotene in *Lilium*, *Fritillaria*, *Kniphofia*, and *Allium* have proved that there is only one split visible throughout, even at the nodes Hence I agree with Gelei, who also made an intensive study of the pachytene stage, that the primary split alone opens out at diplotene

The Discovery of Tertiary Man[1]

By Prof HENRY FAIRFIELD OSBORN, For Mem R S, Research Professor of Zoology, Columbia University, Honorary Curator of Vertebrate Palæontology, American Museum of Natural History

THE discovery of Quaternary man was the central biological achievement of the nineteenth century For twenty four centuries the largely speculative idea of a natural rather than a supernatural origin of man had been slowly developing through the observations of zoologists and the dissections of comparative anatomists From the time of Anaximander (B C 547), of Galen (A D 131), of Leibniz (1700), of Buffon (1755), of Goethe (1790), of Erasmus Darwin (1794), of Lamarck (1809), of Chambers (1844), of Leidy (1847–73) to that of Charles Darwin (1859–71) one bit of evidence after another was added from comparative anatomy, until in the sixteenth century comparative zoology contributed the strong likeness to man of the anthropoid apes—the chimpanzee and gorilla of Africa, the gibbon and orang of eastern Asia The most significant and prophetic observations in comparative anatomy were those of Goethe in the discovery of a separate intermaxillary bone in the upper jaw of man which both he and Leidy rightly interpreted as linking man with the apes and other primates in which the upper jaw is composed of two bones Up to 1859, the relatively new science of palæontology had thus far contributed nothing because the female Neanderthal skull of Gibraltar in 1848 and the male Neanderthal calvarium of Germany in 1856 were misinterpreted by Virchow, Huxley, and other anatomists

I emphasise comparative anatomy and zoology, for as regards *direct* evidence our speculative position toward Tertiary man in 1929 is very much the same as Lamarck's and Darwin's speculative position toward Quaternary man between 1809 and 1871, because we are still largely dependent upon the facts afforded by comparative anatomy and comparative zoology, in the absence of direct palæontological evidence in Middle and Lower Tertiary time This statement is not true as regards *indirect* evidence, for human palæontology is now in a very strong position even to the very base of Quaternary time, a period estimated by geologists at 1,250,000 years Fossil human remains of more than a hundred Quaternary individuals have been found, including *Palæanthropus Neanderthalensis* of Neanderthal, 48 +, *Homo sapiens* of Cro Magnon and Chancellade, 42, 2 of the Trinil race of Java (1891), *Pithecanthropus erectus*, 2 of the Piltdown race, *Eoanthropus dawsoni* 1 of the Heidelberg race, *Palæanthropus Heidelbergensis*, also 1 and possibly 2 more individuals recently reported by Freudenberg under the name *Hemianthropus*, 27 of the recently discovered Chinese *Sinanthropus Pekinensis* (Schlosser, 1903, Zdansky, 1926, Black, 1927–28)

All these human fossils constitute a firm and broad human palæontology for Quaternary time and the close of Tertiary time Each generic name, for example, *Palæanthropus*, *Pithecanthropus*, *Eoanthropus*, *Sinanthropus*, and *Homo*, demonstrates an entirely distinct branch of the fossil human families of Quaternary time, each branch is known to palæontologists as a *phylum* and the special scientific analysis of these several branches is termed *phylogeny* Phylogeny is a relatively new and very important branch of biology, the principles of which were entirely unknown to Darwin (1859–71) and only in part known to Huxley, as they are now revealed by the brilliant and world wide discoveries by invertebrate and vertebrate palæontologists My forecast of the Tertiary anatomy and habits of the 'dawn man is greatly influenced by our direct knowledge of the phylogeny of other mammals

As Quaternary fossil man was the central biological contribution of the nineteenth century so Tertiary man constitutes the goal and peak of biological discovery in the twentieth century Thus far I have been dealing with well known facts because these Quaternary fossil men have become household words all over the world On the other hand, the discussion of Tertiary man carries us into the unknown, into one of the most interesting fields of human speculation and anatomical controversy, into several divergent camps of human opinion and interpretation, along several great lines of comparative anatomy of the principal organs concerned, namely, the brain, the skull and jaws, the limbs, the hands and feet Both with Lamarck and Darwin the 'ape men' descent was never more than a working hypothesis based upon the closer approach of the anthropoid apes to man than that observed in any other group, for want of any positive data Both Lamarck and Darwin postulated a *reversible* evolution in function and structure whereby an animal with all the psychical and anatomical adaptations of arboreal apes could secondarily take on a gradual change of habit and function and gradually enter a new erect career with radical changes in habit and in mind as well as in the anatomy of limbs, hands and feet Darwin's starting point (1871), after picturing as our ancestor a hypothetical ape not far from a primitive Miocene chimpanzee, concluded with the following all important sentence both as to habit and habitat

The foot was then prehensile, judging from the condition of the great toe in the fœtus, and our progenitors, no doubt, were arboreal in their habits, and frequented some warm, forest clad land

More recently (August 1927), in his presidential address to the British Association, Sir Arthur Keith summed up this hypothesis as follows

DATE OF MAN'S EMERGENCE —It is useless to go to strata older than the Miocene in search of man's emergence, in such strata we have found only fossil traces of emerging anthropoids All the evidence now at our disposal supports the conclusion that man has

[1] Retiring presidential address delivered before the American Association for the Advancement of Science at Des Moines on Dec 27, 1929

arisen, as Lamarck and Darwin suspected, from an anthropoid ape not higher in the zoological scale than a chimpanzee, and that the date at which human and anthropoid lines of descent began to diverge lies near the beginning of the Miocene period On our modest scale of reckoning, that gives man the respectable antiquity of about one million years

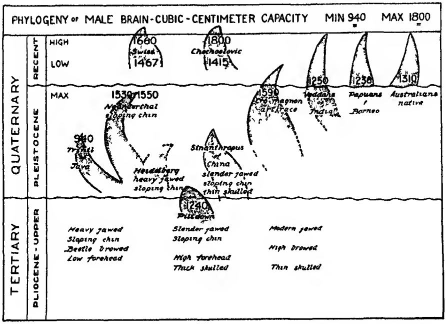
This Lamarck Darwin working hypothesis has been greatly strengthened and in large measure adopted by an army of human and comparative anatomists including all the leading and most brilliant men of our time, such as Sir Arthur Keith (1927), Prof G Elliot Smith (1926–29), Prof William King Gregory, Dudley J Morton, and Robert M Yerkes, as well as by a host of other able but less widely known anatomists So great has been the force of nearly unanimous adherence to the Lamarck Darwin hypothesis that it has gained world-wide acceptance even among the most intelligent scientists, as may be seen in passages in two outstanding works of the present decade, Eddington's "The Nature of the Physical World" (1928) and Jeans's "The Universe Around Us" (1929) A parallel instance of the world wide assumption of a working hypothesis is that of Lamarck's hypothesis of the inheritance of acquired characters as the prime cause of evolution Although never demonstrated, the Lamarckian hypothesis was universally accepted until Weismann gave it a death-blow in 1880 Such may be the fate of the 'ape man' hypothesis

I was myself rather suddenly converted to the opposite 'dawn man' hypothesis in a roundabout manner When in 1919, after years of search, the American Museum discovered in Middle Pliocene time the complete skeleton of a horse named *Pliohippus leidyanus*, a perfect horse in all except name and perhaps colour, the bearing of this case of precocious adaptation on human descent flashed across my mind, and before a meeting of the National Academy of Sciences I predicted that the greatest surprise in store for twentieth century science would be in the discovery of a large-brained Tertiary man! This anatomical prophecy has unexpectedly been confirmed by recent palæontological evidence that *Eoanthropus*, the 'dawn man' of Sussex, is of Upper Pliocene or Tertiary age

The large brain of *Eoanthropus* suggests as our first quota of counter evidence a review of our greatly enriched knowledge of the Quaternary fossil brain

BRAIN SURPRISES OF QUATERNARY DISCOVERY

These surprises arise from the profound researches and independent discoveries of Dubois, Smith Woodward Boule, Keith, McGregor, Black, Economo, and Leboucq, to which honour roll we should add Frederick Tilney's "The Brain from Ape to Man" (1928) The six outstanding points as to the brain are as follows (1) that certain races of fossil man of the last 1,250,000 years had a brain cube equal to or greater than that of modern man, (2) that the much despised cave man (*Palæoanthropus*) was inferior to ourselves neither in brain cube nor in hand ability, although far inferior to ourselves in civilisation, (3) that certain of the cave men (*Homo sapiens* Cro Magnon) were our superiors both in average brain capacity and in average artistic ability, (4) that at the close of Tertiary time there lived a race (*Eoanthropus dawsoni*) with a brain cube equal to the minimum of that of the living Veddahs, Papuans, and native Australians, (5) that the ratio of human brain weight to body weight in Quaternary time was



Photo] [American Museum of Natural History New York

FIG 1

apparently the same as it is to day, namely, 1 50 (Weber, 1896), in contrast to the anthropoid apes, in which it is as follows

	Brain to body weight ratio
Super arboreal Gibbon of south east Asia (130 gm)	1 66 or 1 73
Arboreal Chimpanzee of west Africa (412 gm)	1 51 or 1 61
Super arboreal Orang of Borneo (400 gm)	1 183 or 1 194
Terrestrio arboreal Gorilla of central and west Africa (565 gm)	1 150 or 1 200

(6) as Dietrich has shown, *Pithecanthropus*, the Trinil race of Java, is not an ancestral Pliocene type, as was formerly supposed, but a surviving mid Pleistocene branch, the companion of a stegodont elephant, the Trinil brain is a case of arrested development

The conclusion is inevitable that *the main cubic evolution of the human brain took place during ante cedent Tertiary time and not, as we formerly thought, during the Quaternary age of man or Glacial period*

These six points are supported by the following comparison

	Brain cube in c c
Summit of Quaternary and *Modern* time	
Homo sapiens, Cro Magnon of Mentone	1550
Palæanthropus, Neandorthal Caveman, La Chapelle aux Saints	1530
Homo sapiens, average modern Swiss	1467
,, ,, average modern European	1450
,, ,, Alpine race of Czechoslovakia	1415
,, ,, fossil Alpine race of Ofnet	1400
,, ,, native Australian race	1310
,, ,, native Indian Veddahs	1250
Mid Quaternary	
Pithecanthropus erectus (Trinil man of Java)	940
Summit of Tertiary	
Eoanthropus dawsoni (Piltdown Dawn Man)	1240
Living Papuans of New Guinea	1236

It is well known that the *brain cube* is not a trustworthy test of brain power or capacity, as Leboucq has recently pointed out in striking examples from recent times

	Brain weight in grams
Tourgenieff, Russian novelist	2,012
Cuvier, founder of palæontology	1,829
Byron, poet	1,807
Gambetta, statesman	1,246
Anatole France, littérateur	1,017 (to 1,317)

Doubtless this *cube versus intelligence* disparity in brain function also prevailed during the Quaternary age of man, although in the few fossil cases where comparison is possible we note a similar disparity between male and female brain weight

We must, therefore, adduce collateral and very substantial proof that Upper Tertiary man, whom we may provisionally designate 'the dawn man' after Smith Woodward's well chosen term *Eoanthropus*, made highly intelligent use of his 1240 1300 cubic brain measurement

This brings us to the most startling discovery of the twentieth century, the full significance of which we have only recently learned to estimate

THE FIRST POSITIVE DISCOVERIES OF TERTIARY MAN

Archæologists are still divided as to the human origin of *eoliths*, so that we cannot class these rude flints as positive evidence

One of the most striking coincidences in the history of human palæontology is that indubitable flint implements of Tertiary man were discovered by J Reid Moir on the east coast of Anglia in the year 1909, and that in 1911 only two years later, an indubitable human skull and jaw of what proves to be Tertiary man were found in Piltdown, Sussex, by Charles Dawson It has required eighteen years of research by Moir and Smith Woodward, aided by the most able archæologists and anatomists of the world to establish the full significance of these epoch making discoveries of 1909–11 By adding year by year implement after implement from two strata of Upper Pliocene time, J Reid Moir, originally an amateur collector of Ipswich, has finally overcome all incredulity and even hostility and has thoroughly established the Red Crag and sub Red Crag strata of the Upper Pliocene coast of Anglia as the site of a widespread and highly varied flint and bone industry, including the 'eagle's beak' (rostro carinate), 'skin cutter', 'side scraper', 'push plane', 'borer' and 'chopper' and 'piercing tool', all indicating a race of hunters highly adept at flint flaking, finally, for killing purposes, a perfected 'sling stone', ranking as a work of Palæolithic art

All of these artefacts have been confirmed and recently embodied in the Stone Age chronology of Abbé Henri Breuil (December 1929) Breuil not only accepts the Tertiary age but also in his latest paper (December 1929) shifts the entire pre Chellean and Chellean flint industries from mid Quaternary down into the base of Quaternary time, namely, into the first Interglacial or Mindel Riss stage, this obviously shifts the pre Chellean and Chellean flint making design and intelligence down close to Tertiary time—in fact, some of Reid Moir's flints are identical with the Chellean artefacts

Meanwhile Osborn, by world wide study of fossil elephants and mastodonts, has firmly established these Reid Moir flint beds as of Upper Pliocene or close of Tertiary time, against the contention of the late Ray Lankester that these flints were early Pleistocene Scarcely less positive is Osborn's determination, with the aid of Reid Moir, Freudenberg of Heidelberg, Matsumoto, and Bather and Hopwood of the British Museum, that the Piltdown race—*Eoanthropus dawsoni* of Smith Woodward—is of Upper Pliocene Tertiary age rather than of Quaternary age as formerly supposed

Both the Red Crag of Suffolk and the Piltdown beds of Sussex yield a very primitive species of elephant generally known as *Elephas planifrons* (first discovered (1858) by Falconer in the upper Siwaliks of India) the migrations of which are now traced (Broom) from the Vaal River of South Africa northward into Italy and England, far eastward into India, with absolutely definite measurement and form of the enamelled ridge plates of the grinding

teeth which in the elephants and mammoths give us ***a new and quite dependable means of dating all the fossil man discoveries of Upper Tertiary to recent time*** Upper Tertiary man is thereby shown to have been an elephant hunter, probably for bone and ivory as well as for flesh, more than a million years ago This discovery also paves the way for the great inter continental migration routes and the African Eurasian dispersal of man even in as re mote a period as the Upper Pliocene

In view of the fact now established that even in the Upper Pliocene man was an extremely adept flint worker, with deft hands and fingers guided by an imaginative and intelligent forebrain, it seems probable that Upper Pliocene man, like his companion the Upper Pliocene elephant, was already a nomad and needed long and agile lower limbs as his only means of distant transportation We are thereby forced to reconsider Darwin's concept of the primitive ape man as inhabiting a 'warm, forest clad land "

TRAVELLING LIMBS AND TOOL MAKING HANDS

Fifty eight years of incessant zoological and com parative anatomical research have been focused upon the anatomy and embryology of the apes and man to find out the bearing of the recapitulation or biogenetic principle of Haeckel on the ancestral Tertiary hands and feet of man Recently, Morton (1927), Schultze (1925-29), Straus (1927), Gregory (1925-29), Hrdlička (1928), have devoted special memoirs to this problem, Straus summing up in the paraphrased words The foot of embryonic man is of a structure unfitted for an upright terrestrial existence It is in most characters not unlike that of an adult gorilla, although in some respects even more primitive than that of the largest anthropoid apes The chief point of embryonic resemblance is in what Darwin termed 'the prehensile big toe', but the palæontologist Matthew (1928) has pointed out that all primitive Eocene mammals, both arboreal and terrestrial, had the big toe well set apart from the others This stronghold of 'pre hensile big toe' evidence, therefore, carries man far back of the highly specialised anthropoid ape big toe stage and tends to sustain the 'dawn man' contention that even the embryonic foot of man may date back to the more remote Upper Eocene time

This contention is even more strongly borne out by the embryonic human hand, in which there is no evidence whatever of having passed an anthropoid ape limb-grasping stage While the newest analysis of the embryonic hind limbs may leave us in doubt as to a possible case of reversed evolution from the Miocene ape leg to the human stage, the human hand and the human brain, especially in the light of *Eoanthropus* discoveries, seem to dissipate some of the doubts raised by the feet and strengthen the new 'dawn man' hypothesis of a very remote separation of our running and tool making ancestors of the plateaux and savannas from the same great stock (Anthropoidea) which independently gave rise to the tree-loving anthropoids of the tropics

No one should misunderstand the 'dawn man' hypothesis I have been advocating in a series of papers and addresses since April 7, 1927 I am not ignoring the strong evidence for an Eocene arboreal stage in our ancestry, I am not ignoring the overwhelming evidence of a remote community origin between man and the anthropoid apes, I am combating the special feature of the Lamarck Darwin hypothesis that man once passed into highly specialised arboreal adaptations attained by the Miocene apes, finally, I am inclined to separate the human stock at a geologically earlier pre-Miocene period of anthropoid evolution In the geological remoteness of this momentous separation of the 'dawn man' stock, we are aided by a mass of collateral evidence utterly unknown in the time of Darwin

This brings us back to the sub science of phylogeny spoken of above, which, in popular terms, aims at the reconstruction of the family tree of man by principles recently discovered in the family trees of other mammals

NEW PRINCIPLES OF PHYLOGENY APPLIED TO MAN

First, we have discovered that the geological period of separation of the adaptively radiating branches in many families of mammals is of an antiquity undreamt of even a few decades ago Even in Lower Eocene time, all the existing families of hoofed mammals, such as the horses, tapirs, rhinoceroses and titanotheres, had widely separated from each other in tooth, limb, hand, and foot structure Before the close of Eocene time, these branches were further subdivided into forest loving and plateau loving types, in every branch the forest-loving types were stationary or regressive Similarly, by the close of Eocene time the mastodont and elephant families are found widely separated into five greater branches (in Oligocene time there were numerous sub branches and in Miocene time eighteen distinct branches) In the succeeding Oligocene time, we discover a sharp and world wide division between plateau loving and forest loving types, in the forests remain all the backward conservative types, on the plateaux and uplands are found the alert progressive forward looking types, including all the long hind limbed bipedal animals adapted to rapid progression in an open or partly forested country It is no exaggeration to say that at the dawn of Oligocene time all the plateau loving animals are distinctly modernised both in habits and in bodily proportions

Is it likely that the primates alone escaped this divorce between backward, forest loving life and forward, plateau, savanna and upland life, especially as Eocene forest areas in every continent began to contract and upland open plains and plateaux began to expand ?

A second principle of modern phylogeny is that every ancestral stage, whether of horse, rhinoceros, or elephant (the three kinds of animals I have most intensively studied for the past thirty years), preserves the hundred per cent *structural equipment* for giving rise to its more recent or modernised descendants, each branch has the potentiality of the remotest twigs of descent Through change of function Nature may transform an organ, but it

can never restore a single lost part, whether it be a lost tooth, a lost digit, a lost ankle bone or rib, a lost tendon or nerve. This is Dollo's principle that *the evolution of anatomical organs is never reversible even though the evolution of functions and habits is frequently reversible*. On this principle the human hand could never reacquire the nerves, muscles, functions, freedom, flexibility, and separate innervation lost in the highly specialised arboreal ape hand; the opposable human thumb could not spring back from the partly atrophied anthropoid ape thumb. Our quadrupedal ancestors certainly had a forefoot capable of developing into the human hand with its long flexible fingers separately innervated and its thumb which, as Erasmus Darwin postulated, could reach the tip of each finger in turn, all depending upon separate innervation from special cell centres in the spinal cord and brain. Primitive man is not only a tool making animal, he is also a music making animal; consider 'Blind Tom', the negro musical genius of his day, who not only possessed an excellent finger technique but also a marvellous musical memory that enabled him after a single hearing to repeat elaborate piano compositions. In this human hand connexion let us recall also the researches of Sir Richard Paget in advocating the gesture origin of human speech, as gesture demands flexible fingers.

Third, to this hundred per cent structural equipment of our remote ancestors phylogeny adds a hitherto unperceived germinal potentiality of specialisation along certain predetermined directions rather than others in adaptive reactions to changes of environment; this *teleogenesis* rests upon thousands of observations among primates, horses, titanotheres, and elephants which prove that parallel anatomical and psychical progress is traceable to germinal community of origin. The psychic resemblances of the apes to man are partly parallelisms, partly common inheritance (Yerkes). Teleogenesis is not to be confused either with the old 'teleology' nor is it a revival of a hypothetical vitalism or internal perfecting tendency.

Finally, and perhaps from glandular impulses (Keith), phylogeny proves that independent of selection, of environment, of habit, certain phyla exhibit rapid or accelerated physical and mental adaptation, while others are held back. The creative brain, the tool making hand, the fleet hind limb of man apparently combine in accelerated adaptation, while forest loving primates advance much more slowly.

FIG 2. Osborn's present theory of the ascent and phylogeny of man.

Left: Family of man (Hominidæ), dividing into the Neanderthaloid and modern racial stocks; present geological location of the Piltdown, Heidelberg, Trinil, Neanderthal, and Rhodesian fossil races. Right: Family of the apes (Simiidæ), including the Pliocene and Miocene dryopithecoids nearest the ancestral stock of the Anthropoidea; also the lines leading to the gorilla, orang, chimpanzee, and gibbon. Below: Anthropoidea, the common Oligocene ancestors of the Hominidæ and of the Simiidæ.

Does not this unbiased survey of recent discoveries in archæology, human and comparative palæontology, human and comparative anatomy, compel us to reconsider the classic Darwin Lamarck hypothesis and to substitute a new hypothesis? The new hypothesis carries us into a geological antiquity hitherto undreamt of. Anthropology is forced to share with chemistry and physics entirely new notions of space and time. To my mind, the human brain is the most marvellous and mysterious object in the whole universe, and no geological period seems too long to allow for its natural evolution.

The Tannic Acid Treatment of Burns

BURNS or scalds of relatively small areas of the body frequently have a fatal ending, especially in children, so that any method of treatment which will reduce this mortality requires careful examination and adoption if proved successful In 1925, E C Davidson described a method of treatment by means of tannic acid which he had found reduced the mortality from these injuries, and the treatment has been put to a critical test by W C Wilson in the wards of the Royal Edinburgh Hospital for Sick Children and the Royal Infirmary, Edinburgh, with the result that the mortality has been reduced to little more than a quarter of that observed in another comparable series of cases [1]

The course of events following a burn may be divided into four fairly well-defined stages The first is the stage of reaction to the immediate effects of the injury or stage of initial shock, its clinical features are prostration, low temperature and blood pressure, a small rapid pulse and cold skin It is of nervous origin and is most often only slight in degree After it has passed off the patient appears well for a time, but after about 12 24 hours acute toxæmia or secondary shock appears and may be quickly fatal The chief features of this stage are similar to those of the initial shock, but rapid shallow respiration, vomiting, restlessness, and anxiety, changing to coma, may also be observed, and the temperature is frequently considerably elevated The condition is similar to the secondary shock developing in severely wounded patients, which was proved by experiments carried out during the War to be due to the absorption into the circulation of toxins set free in severely damaged tissues, especially muscle

The work of Dale and his collaborators showed that typical secondary shock was produced by the intravenous injection of such a vasodilator as histamine, and that the vasodilator effects of tissue extracts could be matched by the injection of histamine and cholinc together The isolation of histamine from muscle by W V Thorpe (*Biochem Jour*, vol 22, p 94, 1928) was the final confirmation of these experiments, whilst the work of Lewis and his collaborators showed that the responses of the skin of man to injury and to the injection of minute doses of histamine were identical It may be considered as certain that secondary shock is due to the absorption into the blood stream of some substance which is formed at the injured area itself, Wilson suggests that it is probably a product of protein lysis, it may quite possibly be histamine itself

The third stage is that of septic toxæmia and is only well developed clinically when there is severe infection of the injured area The fourth and final stage is that of healing, and its duration depends largely on the depth of the lesion First and second degree burns heal quickly and without the formation of scar tissue, in the third degree lesions the surface becomes covered with granulations over which the epithelium grows, leaving a supple and greyish white scar in deeper burns, or where sepsis has been a prominent feature, scar tissue development is more marked, and owing to its subsequent contraction, deformities and disabilities may follow

Each of the four clinical stages requires its own treatment For a slight degree of primary shock no special treatment is necessary, but where it is severe, morphine should be given, artificial heat applied, and fluids administered Local treatment is begun at the same time and involves cleansing and dressing of the injured area To prevent secondary shock it is necessary to prevent the absorption of the products of tissue breakdown the only methods which have been at all successful have been excision of the burned area and coagulation of the damaged tissue by tannic acid In the third stage the condition is that of a septic wound and fomentations and antiseptic dressings will be necessary, whilst during the healing stage special measures may be required to prevent contraction

Wilson gives a full description of the method of treatment by tannic acid, and includes in an appendix a description of its use in the first aid treatment of burns In hospital the burned area is first cleansed with ether under general anæsthesia, either gas or oxygen (if shock is marked) or ether being administered The area is then sprayed with a warm sterile 2 5 per cent aqueous solution of tannic acid, freshly prepared, and the parts dried in hot air under a bed cage The spraying is repeated hourly until the area is covered with a firm brown layer of coagulated tissue 8 12 applications may be necessary in burns of the second and third degrees No dressings are required if the whole of the injured area cannot be exposed to the air, compresses of tannic acid are applied to the parts on which the patient lies In most cases the coagulum is left until it peels off, leaving either a healed area or healthy granulations according to the depth of the burn In no circumstances should a moist dressing be applied, since this procedure results in the appearance of toxic signs and symptoms

In this study 117 children were treated by the tannic acid method between November 1925 and January 1929 The mortality was 11 1 per cent, or in 105 children under ten years of age 10 5 per cent In 300 cases under ten years treated by other methods, the mortality was 38 7 per cent The percentage distribution of the mortality over the first three stages was, in the present series, 30 8, 23 8, and 23 8, and in the previous series 2 5, 80, and 15 respectively Thus the tannic acid method of treatment controls the acute toxæmia of the second stage, and by reducing the mortality due to it, brings into greater prominence the fatalities which occur at other stages and in some instances these deaths were not directly connected with the injury

Besides reducing mortality, the treatment lessens

[1] "The Tannic Acid Treatment of Burns", by W C Wilson Medical Research Council, Special Report Series, No 141 Pp 34 (London H.M Stationery Office, 1929) 1s net

the severity of the symptoms at all stages and promotes rapid healing at the same time it permits of the recovery of patients with involvement of a considerable area of the body surface Previously it was considered that burns of 30 per cent of the body surface in an adult and of 11 12 per cent in a child were almost certain to prove fatal From the results obtained in this series of cases it may be concluded that involvement of more than 60 per cent of the surface in children will cause death from shock in a few hours when between 35 and 60 per cent of the surface is affected, the outcome depends mainly on the degree of sepsis which develops and therefore on the depth of the lesion With less than 35 per cent of the surface involved the prognosis is good, provided treatment is begun within a few hours of injury

The results of this method of treatment have been so successful in the hands of Davidson and Wilson that it is to be hoped that many other clinicians will try it out and find it equally satisfactory

Obituary

SIR HENRY JACKSON, G C B, K C V O, F R S

THE death of Admiral of the Fleet Sir Henry Jackson on Dec 14 has caused deep regret in both naval and scientific circles His courtesy his charm of manner, his unswerving devotion to duty, and the sweet simplicity of his nature endeared him in an extraordinary degree to all with whom he came into contact The recollection of their association with him will be a treasured memory to many throughout their lives

Henry Bradwardine Jackson was born at Barnsley in 1855 and entered the Navy in December 1866 During 1878 and 1879 he served on the African station and took part in the Zulu War On returning to England he was appointed to the *Vernon*, where he qualified as a torpedo lieutenant and remained there three and a half years About this time he was sent by the Admiralty to study torpedo design and construction at the Whitehead establishment at Fiume

In 1891 the Navy was seeking some means by which a torpedo boat could announce her approach to a friendly ship, and the idea first came to Sir Henry Jackson of employing Hertzian waves as a means of communication for this purpose He was then at sea and was unable to put his ideas into a practical form until in 1895, when in command of the *Defiance*, he read of some experiments by Dr (now Sir Jagadis) Bose on coherers Having obtained a satisfactory coherer, he managed in this year to effect communication by electromagnetic radiation from one end of his ship to the other During the next two years he continued his experiments with increasing success On Sept 1, 1896, he first met Mr Marconi, and the two pioneers of radio-telegraphy kept in close touch and gave each other much mutual assistance until Sir Henry Jackson was appointed Naval Attaché in Paris early in 1897

In 1899 Sir Henry Jackson was appointed to command the *Vulcan*, and in 1900 wireless telegraphy received definite recognition in the Navy, a contract being placed with the Marconi Company for the supply of installations to a number of His Majesty's ships The new means of communication was employed with considerable success in naval manoeuvres in that year From this time to his promotion to flag rank in 1908, Sir Henry Jackson remained generally responsible for the development of radio-telegraphy in the Navy His own researches were mainly on the lines of improving methods of tuning and the study of the effects of land screening the interference of atmospherics, and the influence of meteorological conditions on radio communications

In 1901 Sir Henry Jackson was elected a fellow of the Royal Society, and in the next year communicated to the *Proceedings* of the Society a paper entitled "On Some Phenomena affecting the Transmission of Electric Waves over the Surface of Sea and Earth" This is now a classical paper and well illustrates the careful and methodical manner in which Sir Henry Jackson always made and recorded his observations In modern radio research, in particular on wave propagation, much attention is given to the results of the mutual interference of several waves arriving at a point with various phase differences In this connexion it is interesting to note that Sir Henry Jackson observed the zones of weak signals, for he wrote " This phenomenon manifests itself by the gradual weakening and occasionally by the total cessation of signals, as the distance of two ships increases, up to a certain point, and their reappearance as the distance is further increased " He went on to say that he considered this effect was due to want of synchronism in the oscillatory discharge between the spark balls of his transmitter, so that there was a change in frequency between the successive discharges of the transmitter This, he pointed out, would produce successive oscillations out of phase with each other which would at one point annul each other, while at a further distance they would reinforce each other

In 1905, Lord Fisher, under whom Sir Henry Jackson had served in the Mediterranean, appointed him Third Sea Lord and Controller In this post his scientific qualifications made him specially suited to take charge of the application of science to the practical work of the Fleet at a time when the design and equipment of warships were undergoing rapid development and improvement

At the beginning of the War, Sir Henry Jackson was retained at the Admiralty, working in conjunction with the War Staff, and was appointed First Sea Lord on May 23, 1915, when Lord Fisher left the Admiralty He held this high office until December 1916 During this period he worked in complete harmony with Lord Jellicoe, and the foundations were laid for various schemes for fighting the submarine menace, including the raid

on Zeebrugge, which were to be brought to fruition later During Sir Henry Jackson's period of service as First Sea Lord the Battle of Jutland was fought In this connexion it is interesting to notice the faith he always had in wireless methods During the discussion at the Institution of Electrical Engineers of a paper by Capt Round on radio direction finding, he revealed that the evidence which finally convinced him that the German High Sea Fleet was really coming out was the observation made by a radio direction finding station of a change of bearing of 5° in the position of a German battleship

After rendering invaluable service to the nation, Sir Henry Jackson was promoted Admiral of the Fleet in 1916 From April 1917 to July 1919 he had the honour of serving as First and Principal Aide de Camp to the King He retired from the Navy in July 1924

In 1920 the Lord President of the Council appointed Sir Henry Jackson as the first chairman of the Radio Research Board of the Department of Scientific and Industrial Research At the time of the formation of the Board the rapid development of radio communications had caused technical application to outstrip fundamental knowledge of the subject The taking up once more of the scientific aspects of radio-telegraphy was a task which was completely congenial to Sir Henry Jackson Under his guidance, more than one hundred important papers have been published dealing with such subjects as the propagation of waves, the nature and origin of atmospherics, radio direction finding, and the measurement of electrical quantities at high frequencies It is characteristic of him that although he gave his personal attention to the work described, yet he never desired to claim personal scientific credit for any of the results obtained His helpful and kindly criticism, and his generous spirit, had the inevitable result of creating feelings of the utmost devotion in the staff whose work he supervised In 1926 the Royal Society awarded him the Hughes medal in recognition of the high merit of his work This honour gave him very great gratification

In addition to supervising the work of the Radio Research Board, Sir Henry Jackson did much private experimenting With apparatus of his own design and manufacture he carried out pioneer work on the reception of short waves Some of his most striking results in this connexion were referred to by him in a contribution to a discussion arranged by the Royal Society on the electrical state of the upper atmosphere

Sir Henry Jackson was secretary, and later chairman, of the British National Committee on Radio-Telegraphy formed a few years ago under the auspices of the Royal Society, in connexion with the International Union for Scientific Radio-Telegraphy His contributions to the meetings of the general assemblies of the Union had the result of placing British prestige in the scientific aspects of radio telegraphy on a very high level

In 1890 Sir Henry Jackson married Alice, daughter of Mr S H Burbury, F R S The Burbury family were also pioneers in radio telegraphy, and many early experiments were carried out by them and Sir Henry Jackson in the grounds of their house in Yorkshire

Sir Henry Jackson was a member of the Institution of Electrical Engineers, honorary vice-president of the Institution of Naval Architects, honorary D Sc of the Universities of Oxford and Leeds, honorary LL D of the University of Cambridge, and vice president of the Seamen's Hospital Society He was created K C V O in 1906, K C B in 1910, and G C B in 1916 on his retirement from the post of First Sea Lord

Mr P H Hepburn

Patrick Henry Hepburn was born in 1873 and educated at Charterhouse and at Amersham Hall School near Reading He obtained a First Class Honours for the London LL B degree and followed his father's profession as a solicitor He was a man of many interests In 1902 he made a large collection of photographs of Norman churches round Caen to test a theory that the Gothic cross vault was a development of the Angevin dome Before the War he was fond of boating and swimming, and bicycled all over England and Scotland and large parts of France and Belgium Until recently he frequently bathed in the middle of winter in the Serpentine He would take lonely walks over mountains and fells at night, and only two years ago was found in an exhausted condition and taken to a neighbouring inn This pursuit led to the accident which caused his death Walking by night in the Lake district, he fell into a river and apparently struck his head on a rock and was drowned During the War his adventurous spirit led him to join the balloon section of the Naval Air Service An exciting incident occurred on one occasion Going up at Richmond to a 'blimp' stationary balloon with a mechanic to make some repairs, they were caught by a line squall and the balloon was torn from its moorings and turned completely over The occupants managed to hold on, the balloon righted itself and came down safely in Suffolk He served in East Africa, where he was disappointed in not being able to climb Kilimanjaro, and afterwards in the Mediterranean In Gibraltar he was a friend of the padre and used his library to learn Hebrew

Mr Hepburn's interest in astronomy began in the early 'nineties with the purchase of a 3 inch telescope He was interested in eclipses and went to Vadso in 1896, to Spain in 1900 and 1905, and to Normandy in 1912 In 1914 he went with the Greenwich observers, Dr Jones and Mr Davidson, to Minsk He was a great help to them in all ways, especially as, owing to the outbreak of war while the observers were in Russia, they were deprived of other assistance which had been promised In 1927 he observed the eclipse with Dr Merton from an aeroplane

Mr Hepburn took charge of the Observatory of the Hampstead Scientific Society at its opening in

1910 and showed Halley's Comet to many people He was always helpful to amateur astronomers and never spared time or trouble when he could assist them He joined the British Astronomical Association in 1896, and took an active part in the meetings from 1912 onwards, contributing numerous papers He served on the council for many years and was director of the Saturn Section He was president in the years 1921–2 and 1922–3, giving addresses on "The Masses, Densities, and Surface Brilliancies of Stars", and a brief summary of the history and recent developments of astronomy He was on the Council of the Royal Astronomical Society and treasurer for the year 1927 In 1911 he purchased a 13 inch reflector and made numerous observations of the surface features and rotation of Saturn He was a most energetic observer, and when a larger telescope than his own was required would come on Sunday nights to Greenwich and use the 28 inch refractor, for which he was well qualified by his remarkably keen sight He would sometimes sit up the whole night, and go to his office in the morning and do his regular day's work, apparently without feeling any effects He was extremely modest about his astronomical work He had a large circle of friends among astronomers, who are deeply grieved by his sudden death, and wish to convey to his widow and children their respectful sympathy F W D

WE regret to announce the following deaths

Dr R Wilfred Balcom, chemist in charge of food control of the Food, Drug, and Insecticide Administration of the U S Department of Agriculture, on Oct 17, aged fifty one years

Prof Ludovico Marini, professor of terrestrial physics in the Universities of Rome and Naples and author of many papers on the climatology of the Mediterranean, on Oct 6

Dr Jan Metzelaar, of the University of Michigan Museum and fisheries expert of the Michigan State Department of Conservation, on Oct 4, aged thirty seven years

Prof P J White, professor of zoology in the University College of North Wales, Bangor, and director of the Puffin Island Biological Station, on Dec 26, aged sixty seven years

News and Views.

ONE of the realisations which have crept into the biological thought of the last decade is that the starting points of the main groups of animals are far more remote in time than had been supposed, and what is true for the great phyla would seem also to be true for many lesser stocks Since the ancestral forms of present day families of hoofed mammals had already attained the characteristic specialisations of their kind in Lower Eocene times, how much more remote must have been the critical point where the common history of the ungulates began Struck by this and other recent discoveries in the principles of phylogeny, Prof Henry Fairfield Osborn has re examined the story of the origin of man in the new light, and has summarised his conclusions in an address delivered at the close of the year to the American Association for the Advancement of Science, under the title, "The Discovery of Tertiary Man" The address, which appears elsewhere in this issue of NATURE (p 53), will be welcomed, since it clearly defines Prof Osborn's position, and must remove the misconceptions to which some of his pronouncements have given rise amongst those anxious to regard every scientific dispute as a nail driven into the coffin of man as a product of evolution He states his case in a nut shell "No one should misunderstand the 'dawn man' hypothesis I have been advocating in a series of papers and addresses since April 7, 1927 I am not ignoring the strong evidence for an Eocene arboreal stage in our ancestry, I am not ignoring the overwhelming evidence of a remote community origin between man and the anthropoid apes, I am combating the special feature of the Lamarck Darwin hypothesis that man once passed into highly specialised arboreal adaptations attained by the Miocene apes, finally, I am inclined to separate the human stock at a geologically earlier pre Miocene period of anthropoid evolution"

THE study of prehistoric man himself, thanks to many discoveries, has made great strides in recent years Fossil remains of more than a hundred Quaternary individuals have now been found, and they show indubitably that in size of brain (apart from the arrested development of the Trinil man of Java) Quaternary man equalled or exceeded modern races of mankind The suggestion clearly is that the early development of the brain of modern man must be looked for in deposits earlier than Quaternary Prof Osborn traces the evidences which point to the existence of Tertiary man, the presence of artefacts in the Upper Pliocene strata of the Red Crag and sub Red Crag, the actual discovery of the Piltdown man, whose association with *Elephas planifrons* indicates his Upper Tertiary origin, and the indirect evidence of the embryonic structures of foot and hand, which carry man far back beyond the specialised anthropoid apes of the present day Prof Osborn is almost overwhelmed by the results of his consideration, for he concludes "To my mind, the human brain is the most marvellous and mysterious object in the whole universe, and no geological period seems too long to allow for its natural evolution" The real conclusion is, not that infinite time must be postulated, but that we have still much to learn about the processes of natural evolution However that may be, we can agree with Prof Osborn that as the discovery of Quaternary man was the central biological achievement of the nineteenth century, so the running down of his Tertiary forbears is likely to be a triumph of the twentieth

DURING 1928 abundant evidence that orang utans were being captured and exported on an unprecedented scale from Sumatra, one of their two island strongholds, aroused concern lest this interesting and

scarce anthropoid ape should be exterminated The capture was illegal, for already in 1924 and 1925 the Government of the Netherlands East Indies had declared it to be a punishable offence to hunt, catch, kill, or to possess or to keep, either dead or alive, the orang utan within the whole area of the colony But the law was difficult to enforce, especially in face of the demand abroad for living specimens and the large prices which were being offered The wholesale exports of 1928, however, brought the matter to a climax, and widespread protest was made by naturalists and scientific societies in Great Britain against the obnoxious trade We are pleased to be able to report that the agitation on behalf of the orang has had a successful issue From the *Times* of Dec 31 last we learn that Lord Passfield, Secretary of State for the Colonies, in reply to a dispatch sent from Sir Hugh Clifford before he left Singapore, has approved the introduction of legislation to prohibit the importation of orangs into the Straits Settlements and the Federated Malay States The question was taken up at the request of the Netherland Indian Government, and Sir Hugh Clifford and his executive council agreed that British Malaya might properly co operate with the Government of the Netherlands East Indies to prevent the extinction of the species Now that the approval of the Colonial Office has been given, a Bill will speedily be introduced to make the agreement effective

THE New Year honours list contains the names of the following men of science and others associated with scientific work —*Baronets* Sir Gregory Foster, who has just retired from the post of Provost of University College, London, and was recently Vice Chancellor of the University, Sir Eustace Tennyson D'Eyncourt, at one time Director of Naval Construction, Admiralty *K C M G* Lieut Col Andrew Balfour, member of the Colonial Advisory Medical and Sanitary Committee and Director of the London School of Hygiene and Tropical Medicine *Knights* Prof. T P Nunn, Principal of the London Day Training College, and professor of education in the University of London, Mr Archibald Page, Chief Engineer and Manager of the Central Electricity Board and a past president of the Institute of Electrical Engineers, Mr Alexander Rodger, Inspector General of Forests, Government of India, Prof T Zammit, Curator of the Museum, Malta *C I E* Mr B C Burt, Imperial Council of Agricultural Research, India, Mr. H L Newman, Chief Conservator of Forests, Bombay, Mr S Walker, Chief Engineer and Secretary for Irrigation, North West Frontier Province, India. *C B E* Prof. J S S Brame, professor of chemistry and metallurgy, Royal Naval College, Greenwich, Mr G E S Cubitt, lately Conservator of Forests, Straits Settlements and Federated Malay States, Capt A T A Dobson, Assistant Secretary, Ministry of Agriculture and Fisheries *O B E* Mr Joseph Jones, formerly Curator of the Botanic Gardens, Dominica, Mr W A. S Lamborn, medical entomologist, Nyasaland Protectorate, Capt R N Liptrot, principal technical officer, Air Ministry, Mr W R Mustoe, Superintendent of Horticultural Operations, Delhi, Dr E S Russell, Director of Fishery Investigations, Ministry of Agriculture and Fisheries *M B E* Mr John Aikman, Assistant, Royal Botanic Gardens, Kew, Mr E A Bearder, technical adviser, Dyestuffs Advisory Licensing Committee, Mr A A Gomme, Librarian, Patent Office, Board of Trade

THE French Society of Chemical Industry holds its annual meetings alternately in France and a foreign country, since foreign participants are invited, the meetings rank as congresses Last year's meeting, held at Barcelona in October, was attended by some 270 French and 400 Spanish chemists, and altogether about 17 foreign countries were represented The opening address was delivered by Prof H E Armstrong under the title "Structure moléculaire La vie et la couleur Pensées allégoriques d un chimiste en Espagne" In a recent issue of the *Journal of the Society of Chemical Industry* (Dec 13, 1929, p 1198) Prof Armstrong records some interesting 'after thoughts' on the congress For example, in the course of a journey across Andalusia, from Seville to Granada and back to Cordova, he was impressed by the innumerable rows of olive trees covering the hills "The labour entailed in plucking the fruit must be enormous —the industry can only be possible in a country where the cost of living is very low Travelling hour by hour through such country, the chemist, if taking notice, can but wonder how so modest looking a tree does the trick of making oil Heaven save us, however, from ever manufacturing the oil synthetically and so destroying the peace of mind and rational occupation of multitudes of happy beings engaged upon healthful work consonant with their intelligence Our modern lust to manufacture must be curbed"

A VISIT to the cathedral at Burgos was the immediate cause of a train of reflections which Prof Armstrong expands under the text "We too must build our Cathedrals with utmost magnificence and make them full of clear meaning" He regards it as the province of the man of science to proclaim the infinite wonder and glory of the cosmos and to provide for humanity a living soul, rather than to follow the cult of the world, the flesh, and the devil "Saints enough we already have to range in effigy behind many altars—the story of whose wondrous deeds and prophetic powers may well be told in ways to evoke interest and thankfulness even in the masses Why should we not have our Columbus, our Darwin, our Liebig, our Pasteur, our Volta day? A full calendar of saints who have rendered worshipful service to mankind and set worthy example? Decorative work would be found for artists in every direction a new era would arise from our action, music would flourish and all the arts Unless and until science become thus militant, we shall be little more than slaves of society, mere mechanics Unless scientific workers take constructive action, there will be little or no moral progress, nay, worse, our civilisation may go under There is grave danger that the Churches of to day may lapse into the hands of the ignorant, as knowledge spreads and the more intelligent can no longer follow their doctrines" Like Kekulé, the doyen of British chemistry has learnt to

dream, and his waking thoughts, always interesting, are often provocative. The views upon synthesis, religion, and other matters which he unfolds in this contribution will perhaps be held by the orthodox to bear the taint of heresy; nevertheless, they are bound to meet with a good deal of general sympathy and to stimulate thought and discussion.

THE Empire Marketing Board has appointed a Committee to advise on the "Infestation of Stored Products by Insects and Fungi", of which the membership is as follows: Mr. E. M. H. Lloyd (chairman), Mr. H. Brown, Dr. E. J. Butler, Dr. P. A. Buxton, Mr. J. C. F. Fryer, Mr. F. Laing, Mr. T. W. Macara, Dr. J. W. Munro, Dr. J. G. Myers, Mr. H. C. Sampson, Prof. V. H. Blackman, Mr. W. S. Thomson (secretary). By a series of grants made to the Imperial College of Science and Technology, the Board has enabled the College to establish at Slough a station for the conduct of research on the infestation of stored products. This work is under the direction of Dr. J. W. Munro, assistant professor of entomology in the College, and has been planned along lines similar to those laid down in the Tenth Report of the Royal Society (War) Committee on Grain Pests for the continuance of the work on grain pests which it had begun, but which terminated shortly after the conclusion of the War. Thus, the work is considered as comprising three main activities: survey or intelligence work, biological and mycological research, and the application of research results to the control of insects and moulds. The survey or intelligence work is carried out mainly at the London docks, with occasional work at Bristol and Liverpool. The biological and chemical research work is carried out at the Biological Field Station at Slough, but the application of results to practice has not yet been carried out except on a small scale because, as is obvious, successful application requires fuller knowledge than can be obtained in the short space of time during which work has been in progress. For the present, the research in progress is concentrated on cacao, copra, and dried fruits, but other products are also receiving attention, and the whole field of stored products in entomology and mycology will be explored as time and opportunity permit.

SIR HUBERT WILKINS has made further discoveries in Antarctica to the south of Graham Land. In a recent dispatch to the *Times*, he describes how he launched his aeroplane from the research vessel, *William Scoresby*, to the west of South Graham Land. The first attempt on Dec. 28 was a failure owing to a heavy snowfall obscuring visibility and necessitating a return. Three days later a start was made from the ship at the edge of the pack ice 115 miles from the nearest land. The exact location is not given. Charcot Land was found to be an island, as was expected, and the monoplane continued to the westward along Hearst Land, charting a new stretch of the coastline of Antarctica for about three hundred miles. A later dispatch from the expedition records a severe earthquake at Deception Island on Jan. 3. The aeroplanes of the expedition escaped damage.

CONSIDERABLE progress has been made with electrical heating during recent years, although the cost of electrical energy is higher than the cost of solid and liquid fuels. In many cases the advantages of cleanliness, convenience, and efficiency more than outweigh the increased cost. Some of the London supply companies charge only a halfpenny per unit when the supply is used purely for heating or power. This charge could be considerably reduced if the limitation that the supply must be continuous were removed. Continuous availability necessitates that any such supply must bear its proper proportion of the overhead charges of the power system. If this supply were confined to the 'off peak' hours only, the load on the station would be more constant and an appreciable reduction in the price could be made. In a paper read to the Institution of Electrical Engineers on Dec. 19 on the heating of buildings electrically by means of thermal storage, Colonel Monkhouse and Mr. L. C. Grant described practical installations where this method has been adopted. Water contained in tanks suitably lagged so as to have high thermal insulation is heated during the 'off peak' hours, which are usually a few hours on either side of midnight, and the heat is retained for use until the next heating period comes. They laid stress on the fact that buildings which are to be heated in this way can be built without flues or smoke stacks. Figures were given showing the saving this effects in capital costs in certain cases. At Carliol House in Newcastle, the estimated annual cost for heating by coke in a normal winter was £1882, and for heating electrically it was £1904. In the latter case a saving on the capital cost of £2000 could have been effected by having no chimneys. This is not taken into account in the estimate, neither is the fact that the capital cost of the electrical installation is very high owing to the duplication of all the plant.

THE design of pendants and fittings for lighting rooms is gradually undergoing a change. The general public are becoming accustomed to the new systems which are exemplified in modern kinematograph practice and in stage decoration. A. B. Read, in the *Electrician* for Dec. 27, points out that tubular forms of lighting have developed from the use of tubular and 'striplite' lamps. The greatest use has been made of this system of lighting in Germany, where fittings of one tube, long lines of tube and groupings of tubular shapes have been employed with conspicuous success. Double ended 'striplite' lamps of large diameter are common in Germany. They can be mounted cheaply and produce a pleasing effect. In the old days, electric light fittings were often made to resemble a flower; now more simple and direct designs are used. In modern life, rooms are not decorated to last as long as a life time. It would be advantageous to devote some of the money expended on redecoration to obtain effective decorative lighting. Lighting from large surfaces and panels has been used fairly extensively recently, but a good deal of the interest of the lighting is lost by not having a fitting as a definite source of light. Indirect lighting often fails to produce the pleasure that a well designed fitting does. A well designed modern fitting consists of

four vertical tubes of light with a black mirror centre tube Another consists of three cylinders of glass, the metal-work being practically concealed

IN the next century commentators will scarcely fail to remark on the fact that in the nineteenth and twentieth centuries, cultivated and intelligent people remained apathetic towards the pollution of the atmosphere by smoke They will note the display of resistance, active and passive, towards this hygenic reform, characteristic of slum dwellers, yet exhibited by even the most refined who would never tolerate the least defect in sanitation, public and domestic That reform is in train can scarcely be denied, and one sign is the appearance of a quarterly periodical, *Clean Air*, issued by the National Smoke Abatement Society, 25 King Street, Manchester, for an annual subscription of 2s 6d This reveals the existence of a body of opinion interested in a wide range of activities The first number brings to notice various technical aspects of the question, the use of gas, electricity, smokeless fuels, and smoke reducing accessories to plant A section reporting activities in the municipalities brings to light differences in the stages of advancement of public opinion Some have already in being regional smoke abatement committees, while some of these are in process of formation In the West Riding of Yorkshire such a committee is setting up a scheme of training for stokers and an examination board for their certification The advantages of bringing these activities into a common focus is undeniable

THE Society for Experimental Biology held a conference at the new building of the London School of Hygiene and Tropical Medicine on Dec 20 and 21, 1929 A number of interesting papers were read, including studies on reflex movements in the scallop, by Dr A D Ritchie, the production of formaldehyde during photosynthesis, by Dr M C Pratt, the action of acriflavine on the Protozoan *Bodo caudatus*, by Dr Muriel Robertson, differentiation and growth of the skeleton of the rabbit, by Dr A B Appleton, histological methods for exploring the distribution of biological activity in the anterior pituitary, by Dr E A Spaul, a new hormone from the anterior pituitary, by Dr B P Wiesner, fertilisation and segmentation of rabbit eggs *in vitro*, by Dr G Pincus, the physiology of colour change in Crustacea, by Miss E M Stephenson, and the biology of the parasite *Tylenchus dipsaci*, by Dr G Fox Wilson In the second session a number of excellent exhibits were given, including demonstrations of methods devised for various experimental researches in progress at the London School of Hygiene and Tropical Medicine

AN ingenious device for a self operating meteorological observatory was briefly described by Dr F Nansen at a recent meeting of the International Society for the Exploration of the Arctic Regions by means of Aircraft According to a report that appeared in the Copenhagen newspaper *Politiken*, the Meltchaneff apparatus consists of a small balloon to which are attached thermometer, hygrometer, and barometer constructed of very light materials These instruments record by means of small short wave transmitters which, with a life of about two hours automatically send out signals Records have an accuracy to within one tenth of a degree The apparatus with a weight attached will be dropped from an airship On striking the ice the weight is detached and the balloon with its instruments rises The wireless signals are received by the airship, which is thus enabled to obtain records of a vertical section of the atmosphere whenever it is desirable A further development is even more ingenious Prof Meltchaneff is at work on the details of an automatic observatory weighing $1\frac{1}{2}$ tons which is to be dropped from the airship on to the ice whence it will transmit observation three times a day and function for an entire year He suggests that an airship should be able to carry ten of these automatic observatories on a journey and place them in desirable sites on the land or pack ice An annual visit, presumably by airship, would keep them in repair

AT the meeting of the London Mathematical Society on Thursday, Feb 6, at 5 P M, at Burlington House, Mr J Hodgkinson will deliver a lecture on "Conformal Representation by Means of Lamé Functions" Members of other scientific societies who are interested are invited to attend

AT the instance of the Research Co ordination Sub Committee of the Committee of Civil Research, the Forestry Commissioners have constituted an Advisory Committee on Forestry Research The members of the Committee are as follows Mr R L Robinson (chairman), Dr E J Butler, Dr A W Hill, Dr A S Joseph, Dr Guy Marshall, Mr R S Pearson, Prof R S Troup, Prof Wright Smith, Mr W H Guillebaud (secretary)

AT each of its annual meetings, the American Association for the Advancement of Science gives a prize of 1000 dollars for the most noteworthy contribution to science made at the meeting The New York correspondent of the *Times* announces that the prize for the recent meeting at Des Moines has been awarded to Prof A J Dempster, of the University of Chicago, for a paper showing that protons have wave characteristics Prof Dempster describes some of his work in a communication which appears elsewhere in this issue of NATURE (p 51)

THE fourth General Assembly of the International Union for Geodesy and Geophysics will take place at Stockholm on Aug 15–23, all the meetings being held in the Parliament House save the inaugural meeting, on Aug 15, in the Great Hall of the Concert House The main work of the Union will be accomplished in the meetings of the separate sections, devoted to geodesy, meteorology, terrestrial magnetism and electricity, seismology, oceanography, hydrology, and vulcanology Among the important matters requiring international co operation to be considered at Stockholm will be the organisation and objects of the scheme for a new 'polar year' in 1932–33 The local committee organising the Stockholm meetings has made arrangements for various social and scientific gatherings and excursions during the period of the Assembly, and for more extended excursions, after its conclusion, to the north and south of Sweden

A SPECIAL advance overseas edition of the catalogues of the 1930 British Industries Fair, to be opened in London and Birmingham on Feb 17, is already available, and is being issued immediately to business men in Europe, North America, South Africa, and the eastern coast of South America, including all those buyers who have notified the Department of Overseas Trade of their intention of attending the Fair By this publishing feat, which has only been made possible owing to the keenness of British manufacturers to participate in the Fair, trade buyers in cities so far apart as Istambul, Cape Town, and Vancouver will be able to receive copies of the Fair catalogues before commencing their voyage to England The catalogues, apart from containing descriptive entries of the exhibits of some 1800 British manufacturers, embody a complete classification of the exhibits by trades, and indexes in nine languages

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A technical assistant and a senior technical assistant in the Admiralty Technical Pool, for the Admiralty Compass Department, Slough—The Secretary of the Admiralty (C E Branch), Whitehall, S W 1 (Jan 13) A lecturer in chemistry at the Stockport College for Further Education—The Principal, College for Further Education, Stockport (Jan 17) A senior assistant in charge at the Experimental Station of the Ministry of Transport, Harmondsworth, near Colnbrook, Middlesex—The Establishment Officer, Ministry of Transport, Whitehall Gardens, S W 1 (Jan 18) An inspector under the Ministry of Agriculture and Fisheries, for the purposes of the Diseases of Animals Act, 1894–1925—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S W 1 (Jan 20) A head of the Agricultural Department of the Seale Hayne Agricultural College—The Principal, Seale Hayne Agricultural College, Newton Abbot, Devon (Jan 20) A lecturer in dental histology in the University of Manchester—The Registrar, The University, Manchester (Jan 24) An assistant in the Library of Bedford College for Women—The Secretary, Bedford College for Women, Regent's Park, N W 1 (Feb 1) A junior assistant under the directorate of metallurgical research of the Research Department, Woolwich—The Chief Superintendent, Research Department, Woolwich, S E 18 A trained attendant in the Physiology Department of University College, Cork—The President's Secretary, University College, Cork A junior professional assistant in the Meteorological Office—The Secretary (S 1), Air Ministry, Adastral House, Kingsway W C 2 A laboratory assistant under the Government of Iraq for the Health Department—The Crown Agents for the Colonies, 4 Millbank S W 1 (quoting M/1546) Junior draughtsmen at the Royal Airship Works, Cardington—The Director of Airship Development, Royal Airship Works, Cardington, Bedford Two posts for the regional organisation and development of broadcast adult education under the British Broadcasting Corporation—The Secretary, Central Council for Broadcast Adult Education, B B C, Savoy Hill, W C 2

Our Astronomical Column

Wilk's Comet—The comet is a very easy telescopic object, being visible on Jan 5 through considerable mist The following observation was obtained by Dr A C D Crommelin at Greenwich

U T	R A 1930 0	N Decl 1930 0
Jan 5^d 17^h 48^m 53^s	20^h 38^m 3 92^s	15 24′ 13 7″

The comet is keeping near the ephemeris deduced from Prof Banachiewicz's elements, the ephemeris for 18 hours U T is continued

	R A	Decl	log r	log Δ
Jan 13	21^h 19^m 45^s	N 5° 18′	9 8430	0 0679
17	21 34 51	N 1 3	9 8328	0 0990
21	21 47 33	S 3 2	9 8285	0 1289
25	21 58 0	S 6 37	9 8309	0 1557
29	22 6 55	S 9 53	9 8399	0 1797

Prof G van Biesbroeck at Yerkes Observatory observed a slender tail, 20′ in length, in a direction opposite to the sun A photograph by Dr Waterfield at Baltimore showed traces of the tail

Relation of Light Changes to Velocity Changes in Variable Stars—Mr D B McLaughlin discusses this question in *Astr Jour*, No 932 He begins by directing attention to the facts that in the Cepheid variables the light maxima nearly coincide with the minima of radial velocity, while in the Mira Ceti type the two maxima nearly coincide He has accordingly tabulated the amount of the lag of velocity minimum after light maximum, and expressed the lag as a fraction of the period of the star The results are plotted in a graph, with the logarithm of the period as abscissa and the lag ratio as ordinate The resulting points group themselves along a parabola with axis vertical and vertex on the X axis at a point corresponding to a period of a week, which is noted to be near the position of maximum frequency of the Cepheid variables

The author concludes that all the variables other than the eclipsing ones form a connected sequence, and that the Cepheid type occurs at the point of maximum stability of the pulsations of the stars, which are supposed to produce the variations of light There is one star that deviates widely from the curve, this is *RU* Camelop, the author points out that this star is peculiar in many ways, the shapes of its light and velocity curves are unusual, and its spectral class varies from K to R

Minor Planets—The issue for 1930 of 'Kleine Planeten", the annual handbook issued by the Berlin Rechen Institut, has just appeared It contains ephemerides of all the planets that pass opposition during the year, also of 433 Eros from Oct 1 to the end of the year The nearest approach of the latter does not occur until the end of January 1931, but observations will begin some time before this, it will approach the earth within some 15½ million miles, which is much the closest approach since its discovery in 1898

The planets to which permanent numbers have been assigned now extend to No 1113 It is satisfactory that several of the planets noted as new in the last two years prove to be identical with planets recorded in former years, but not previously observed sufficiently to receive numbers Many of these identifications, which involve great labour, were made by Mr B Asplind, others by L Fabry and S Beljawsky, planet 1074 has been named Beljawskya in honour of the latter

Research Items

Prehistory of the Eskimo.—In vol. 81, No. 14, of the *Smithsonian Miscellaneous Collections*, Mr. Henry B. Collins, jr., describes and figures a number of specimens of the prehistoric art of the Alaskan Eskimo and discusses their relation to the culture and distribution of the modern Eskimo. The researches of Boas and Wissler, reinforced and extended by the results of the Mathiassen First Thule Expedition (1922–24), showed that the ancient eastern culture, now known as the Thule culture, must have originated in Alaska. In 1926 the survey by Hrdlička of the Alaskan coast from Norton Sound to Point Barrow, and the archæological investigations of Jenness in the Bering Sea region, showed that underlying the existing culture of north and north western Alaska was an earlier and generally more advanced culture, marked especially by elaborately carved and ornamented objects of old ivory. This was distinct and new, though some harpoon heads corresponded with Thule types of the east. Excavations by the author on St. Lawrence and Punuk Islands, Alaska, in 1928 showed successive stages of art development of the ancient Bering Sea culture. This culture is the oldest that has yet come to light in the Eskimo north west. It differs entirely from the art of the modern Eskimo, consisting essentially of circles and lines and showing no internal evidence of ever having been associated with realistic patterns, although carved representations of animals are not lacking. Nor is there any real resemblance to the art of the north-west coast, though there is a vague general similarity which may point to a common ancestry. The finds on Punuk and St. Lawrence Islands, however, have revealed a transition stage which justifies the view that modern Alaskan Eskimo art, notwithstanding its differences and its greater simplicity, is directly descended from the old Bering Sea art. While the discovery of this ancient art, which is not primitive, has not clarified the origin of Eskimo culture, it points to the necessity for going further back before that origin is revealed. Yet it is probable that its roots lie in eastern Asia.

Skull Ornamentation in the Naga Hills.—In *Man* for December, Mr. J. H. Hutton describes a method of ornamentation of the skull of a dead chief which is practised among the Konyak Nagas of Assam. Some of the hair of the dead man is stuck on the forepart of the skull, in front of the spot where the hair was parted in life, to form a sort of fringe. The orbits are filled with white pith in the centre of which the eye is represented by a piece of looking glass, and a nose of pith is also provided. The whole is painted with a blue pigment. The skulls are probably kept in pots covered with flat stones, but produced on special occasions and feasted. If so produced they are probably placed on a sort of a seat and covered at the back with a cloth, as is done at Namsang, where, however, the skull is not given artificial eyes and nose and the forehead is provided with a miniature of the chest tattoo pattern. In Kongan paint seems to be used to represent the hair. The practice of providing artificial eyes and nose is comparable with that of Oceania. The specimen obtained lacked the lower jaw. This was due to its sanctity, which was such that the individual who obtained the specimen for the author did not dare abstract the jaw as well. The sanctity of the jaw may be noted in many parts of the Naga Hills. The jaw of an enemy head is separately dealt with in many Konyak villages and does not come with the rest of the skull to the chief's verandah, nor is it separated from the ancestors' skulls. In the Khasi Hills, as in Borneo, the jaw of an animal slain at the funeral feast is the part specially associated with the remains of the deceased. The explanation may be that the ghost attaches specially to the lower jaw.

Bionomics of the Liver Fluke.—I. Clunies Ross records (*Bull.* 43, Council for Sci. Ind. Res., Commonwealth of Australia, 1929) observations on the bionomics of the liver fluke (*Fasciola hepatica*) of the sheep in New South Wales. The miracidia may remain alive and active for twenty four hours after hatching—hatching occurs during the warmth of the day and the miracidia may survive and swim through the night. At 8°-11° C. they may survive for three days. The intermediate host is *Limnæa brazieri*—no other snail was found naturally infected or could be infected experimentally. The cycle of development of *F. hepatica* in this snail is completed in a minimum of forty nine days in summer. So many as 850 cercariæ were found to issue from one naturally infected snail. The majority of the cercariæ encyst on water weeds near the surface of the water, but some at depths of 2 cm. Many cercariæ resisted desiccation in the shade for seventeen days. After entering a new host the cercariæ penetrate the wall of the intestine and enter the liver. Destruction of the liver tissue increases progressively as the flukes grow therein. There is evidence of a protracted stay in the liver tissue—flukes were present there thirty nine days after infestation of experimental animals and none was found in the bile ducts in this period. Development of *F. hepatica* will take place in *Limnæa brazieri* of all ages from a fortnight old to mature specimens. The snail occurs in varied habitats—shallow, marshy areas and swift flowing rivers—and has two breeding periods—spring and summer. It resists desiccation feebly and hence drought exercises a marked influence. The snail is killed in the laboratory by exposure overnight to copper sulphate in dilution up to 1 in 150,000,000, and eggs are usually killed within twenty four hours in 1 in 1,000,000 copper sulphate. Destruction of the snails has been effected by broadcasting, while light rain is falling, copper sulphate (25-30 lb. to the acre of pasture) mixed with four times its weight of sand. Drainage of the pasture is also helpful.

The 'German' Carp.—Prof. W. M. Smallwood and Mary M. Smallwood discuss the problem of the European carp as an American immigrant in the November number of the *Scientific Monthly*. In 1831, carp were first brought from Europe and introduced into New York waters. Since then they have taken so kindly to America that in some parts they are regarded as a menace. The reason for their success appears to be largely in the feeding habits, for they may be said to be practically omnivorous and often feed in polluted areas which other fishes find impossible. They can live and reproduce in lakes, streams, ponds, and canals in very variable conditions, and are usually wonderfully free from disease. Except for a few Acanthocephala, parasites appear to be absent, the reason probably being that they have left behind their intermediate hosts in Europe. There is in this paper an interesting account of the life history of the carp from egg to adult, with notes on their feeding habits.

Growth of Hawaiian Corals.—Under this title Mr. Charles Howard Edmonson has described the continuation of his experimental work on the bionomics of South Sea corals (Bernice P. Bishop Museum, *Bulletin* 58, Honolulu, Hawaii, 1929). In his former paper in the same publication (No. 45, 1928), "The

Ecology of an Hawaiian Coral Reef", many interesting experiments were described, and in the present part it is shown that still more have been successfully carried out. Much of the new work is in connexion with the planulæ and their post larval development, and three species have been studied, *Dendrophyllia manni*, *Pocillopora cespitosa*, and *Cyphastrea ocellina*. As was previously observed, the planulæ are more resistant to abnormal conditions than the adults of the same species, and they settle and become fixed under a wide range of conditions in the laboratory, frequently in clusters. The species vary in their rate of development, *Pocillopora* before fixation being more rapid than *Cyphastrea*. *Dendrophyllia* can develop even in the total absence of light. In its natural surroundings it thrives under ledges of rock where the light is subdued. The planulæ of *Cyphastrea* were much more easily obtained than the other two, and colonies could almost always be made to release them by gently heating the water surrounding the corals or by plunging them into water of about 35° C. Besides the work on the planulæ, the growth of the shallow water corals was studied. These growths are usually very irregular, although they may be large at times. *Porites* in both massive and branching forms may gain so much as 10 mm in height annually, the massive form 60 per cent, the branching form 80 per cent in weight. *Pocillopora* increases on an average about 15 mm in height annually and more than 100 per cent in weight. The variety *nobilis* can increase in height at the rate of about 40 mm in a year.

Observations on Living Chromosomes in *Obelia*.—The oocytes of *Obelia geniculata* prove to be exceptionally favourable for the study in life of the prophases of the first oocyte division. Miss G. H. Faulkner (*Quart. Jour. Micr. Sci.*, vol. 73, Part II, 1929) records that, owing to the transparency of the medusa and of the yolk of the oocyte, the whole of the nuclear cycle can be examined in detail in living specimens, and that isolated individuals can be re-examined from day to day. In the young resting oocytes the nucleus is almost entirely filled with the nucleolus, which represents a condensed chromatic spireme and includes the whole chromosomal content of the nucleus. During the early growth phases of the oocyte, the nucleolus elongates and fragments, and each fragment has been identified as a pair of homologous chromosomes indistinguishably united. Later, each of these bivalent elements divides into two individual chromosomes. The two components of the largest bivalent element are unequal in size and probably represent an *X Y* pair. The chromosomes at the bivalent and at the univalent phase are seventeen and thirty-four respectively. At a still later stage, the chromosomes fragment into numerous small globules which become evenly distributed throughout the nucleus, and the latter is then seen as a clear vesicle. These observations made on living oocytes have been confirmed in sections of fixed specimens.

Fossil Brachiopods.—An alphabetical list of all the known genera of fossil Brachiopods, with their genotypes, synonyms, systematic position, and geological distribution, has been brought together by C. Schuchert and C. M. Le Vene (*Fossilium Catalogus*, I, Animalia, Pars 42. Berlin: W. Junk, 1929). 702 genera are known, of which 456 are found in the Palæozoic, 177 in the Mesozoic, and 74 in the Cainozoic and Recent. A revised classification of the Brachiopoda is given but without diagnoses of the groups. The order Palæotremata, established by Thomson, is adopted.

Form of Volcanoes.—Most Japanese volcanoes, as Prof. T. Terada remarks, in an interesting paper (*Earthq. Res. Inst. Bull.*, vol. 7, pp. 207-221, 1929), are surrounded by a conspicuous zone of depression. To compare the forms of different volcanoes, he takes the average heights of the surface at given distances from the summit in the sixteen principal directions, and from these he obtains the mean profile of nine Japanese volcanoes. This shows that there is a zone of depression at the foot of the cone, while the land beyond it, between 15 miles and 25 miles from the summit, is generally uniform in level. The depth of the zone of depression below the surrounding ground varies from about 20 ft. to 84 ft.

Origin of Graptolitic Shales.—The view put forward by Marr and by Ruedemann that black shales, containing numerous graptolites with but few other associated organisms, were deposited in the deeper parts of seas similar to the Black Sea, is disputed by Dr. A. W. Grabau (*Mem.* VII, Inst. Geol., Nat. Research Inst. China, 1929). The view that he proposes is that normal graptolite beds were formed on fluviatile plains of the type of the Huang ho of China, the Indo-Gangetic plain of India, the Euphrates-Tigris plain of Mesopotamia, etc. Such plains could exist in all parts of the world in former times as they do to-day, and simultaneous rise of sea-level would inundate them, leaving stranded planktonic organisms like graptolites. During the intervals, only fluviatile terrestrial organisms would be buried in the sediments. No evidence is given of this assumed world-wide and oft-repeated rise of sea-level, nor are any deposits of fresh-water origin known to be associated with graptolitic shales.

Ice of North-East Land.—During the Oxford Expedition to Spitsbergen in 1924, Dr. K. S. Sandford made a study of the glacial conditions in North-East Land. He has published the result of his observations in articles in the *Geographical Journal* for November and December. The ice-sheet consists of three domes, two in the northern part and one in the south-west. These domes merge in the regions of highland ice the normal conditions of land ice in Spitsbergen where underlying topographical features have a marked effect on the configuration of the ice and the direction of its flow. The ice-free margin to much of the land indicates in its erratic blocks and topography a former greater extension of the ice. A long period of subaerial denudation has left its marks on the glacial topography of this margin. Some pre-glacial river valleys have again been occupied by streams. There seems, however, to be no evidence of a further and recent retreat of the ice on such a scale. In fact, much of the ice seems to be in a carapace stage, neither gaining nor losing and not in active movement. No glacier shows signs of a marked advance, but at the head of Wahlenberg Bay there is evidence of a fairly recent retreat with a zone of fresh boulder clay in front of dead ice. Raised beaches around the island bear witness to past uplift. This was at least 200 feet and is still in progress.

Vibrations in the Atmosphere.—There is some indication from the daily fluctuations in the height of the barometer that the atmosphere may have a natural period of vibration of twelve hours. A fresh attempt to obtain this result from dynamical considerations has been made by Prof. G. I. Taylor in a paper in the December number of the *Proceedings of the Royal Society*, on waves and tides in the atmosphere. On the assumption that the temperature falls off with height at half the adiabatic rate, from 20° C. at the surface to −68° C. in the stratosphere, Prof. Taylor, extending an earlier analysis by Dr. H. Lamb, obtains a value of 1065 feet per second for the speed of long gravity-controlled waves in the air

The waves set up by the eruption of the volcano Krakatau in 1883 had actually a speed of 1046 ± 9 feet per second, and it follows from this agreement with theory that their propagation must have been adiabatic Isothermal changes would, however, give a value not far from the 910 feet per second required by the semidiurnal barometric wave Prof Taylor has also analysed Strachey's curves, showing the first passage of the Krakatau wave round the earth, and has found that the lobed form assumed by the wave front can be explained by the existence of a typical east wind of 12 feet per second, passing continuously into a west wind with a maximum of 31 feet per second at lat 57° N or S He also finds that the equivalent depth of the atmospheric ocean is not more than 5 per cent less at the poles than it is at the equator

Electron Diffraction by Mica—In a paper in the *Zeitschrift fur Physik* for Dec 9, on the diffraction of electron waves by mica, Dr E Rupp discusses some of the earlier results obtained by Kikuchi in this connexion (see NATURE, Feb 9, 1929, p 224) With thick sheets of mica, Kikuchi had obtained the diffraction patterns of a three dimensional array of atoms, and with thin sheets the patterns of a two dimensional lattice, some of the thin sheets which he used were, however, of the order of a hundred atoms thick, and it is not obvious why these should not have produced the same results as thicker sheets Dr Rupp attributes the effect to a generation of heat in the mica when it is bombarded by electrons He supposes that the planes of atoms which produce surface effects are relatively little affected as individuals by an increase in thermal motion, but that they undergo sufficiently large shifts with regard to one another to destroy regular volume interference Dr Rupp supports this explanation by experiments in which he has been able to produce either type of pattern with a single specimen of mica simply by varying the electron current to it With the very considerable disengagement of heat that occurs when electron currents of about 0 1 ampere are supplied at a power of 3 kilowatts, it is possible to obtain the patterns from the plane gratings even with a sheet of mica 10^{-4} cm in thickness

Oxide-coated Filaments—It is well known that the electron current from a hot wire can be increased enormously in certain circumstances by coating it with the oxide of an alkaline earth metal, but that the factors which control the emission are complex Some important investigations on these filaments are described by J A Becker, of the Bell Telephone Laboratories, in the second November number of the *Physical Review* It appears probable that high activity is associated with adsorption of the alkaline earth metal at the surface, and that many of the changes which occur in the emission are brought about by electrolysis of metal or oxygen atoms through the oxide, the value of the filament as a source of electrons, as with composite filaments of tungsten and thorium or cæsium, depending on the fraction of the surface covered by the active metal The efficiency of the latter is reduced if it is covered with oxygen atoms, but is increased if it is free on the side facing towards the vacuum, but anchored by oxygen atoms to the main surface By appropriate control of temperature and electron current, either the alkaline earth metal or the oxygen can be made to evaporate The probable process of electrolysis in the oxide is also described in some detail, and it seems that Ohm's law is not valid, although most of the current is carried by electrons, and a relatively small part by ions

Transmission Line Surges—The extending use of overhead wires for power transmission and for working electric railways has made the problem of protecting the network from interference by lightning and by sparks caused by atmospheric electricity one of considerable commercial importance The earlier methods of dealing with surges of electricity due to lightning discharges are now quite unsuitable and the whole problem has to be solved by purely scientific methods The development during the past fifteen years of high vacuum technique has led to the construction of apparatus which can record the effects of lightning on the overhead wires In particular, the cathode ray oscillograph has proved of great value In a lecture on transmission line surges given by Dr H Norinder to the Institution of Electrical Engineers on Dec 5, he described the valuable work that has already been done in Sweden by the oscillograph, both on the surges caused by lightning flashes on actual circuits and in an artificial way in the laboratory The construction of these laboratory surge generators has been made possible by the use of kenotrons which give a pressure of 200 kilovolts By connecting the condensers in series, pressures of ten times this value have been obtained Dr Norinder emphasised the great difference in the effects produced by direct strokes and those produced by induced charges He gave experimental data on the rate of cloud discharge, together with characteristic records of the discharge rate He considered that it is not yet possible to deduce definite conclusions as to lightning surges from the records obtained Further research is urgently required In the discussion, Mr Goodlet, of Metropolitan Vickers, mentioned that his firm has made elaborate researches at Trafford Park with impulse generators producing 1,500,000 volts

X-Rays in the Examination of Coal—Röntgen's discovery of X rays was quickly applied to the needs of clinical medicine and surgery, where a method of examining an opaque living object without disturbance received immediate recognition As time went on, industrial applications were developed in one direction after another Mr C N Kemp's application of X rays to the examination of coal and coke for incombustible impurity may become one of the most important of these It was described in a recent lecture before the Royal Society of Arts (*J R S Arts*, p 114, 1929) Coal is not only opaque but also relatively inert to reagents and solvents Quick analytical separations are precluded The normal mode of determining ash is such as to be incapable of giving an indication of the way in which the ash is distributed in a lump Yet this information is vital to a decision as to the feasibility of coal cleaning Mr Kemp has devised a technique which may well bring an X ray apparatus into every coal-cleaning plant and coal testing laboratory in the near future If the retailer of footwear can use X-ray apparatus, why not the colliery?

Synthesis of Glycine—Methyleneaminoacetonitrile (CH_2 N CH_2 CN)$_3$, which can be prepared from formalin, ammonium chloride, and alkali cyanide, when treated with acid is converted into aminoacetonitrile, which is best separated as the acid sulphate This method of preparation is due to Klages (1903) There is some difficulty in obtaining free glycine from the salts, but in the November number of the *Journal of the Chemical Society*, H King and W K Anslow describe a method which gives a yield of 83 per cent, calculated on the nitrile, of the recrystallised glycine, which consists in boiling the acid sulphate with 27 per cent barium hydroxide solution until evolution of ammonia ceases

The Fifteenth International Geological Congress, South Africa, 1929

THE recent meeting of the Fifteenth International Geological Congress during July and August of last year (under the presidency of Dr A W Rogers), with Pretoria as its headquarters—the first occasion on which the *venue* was in the southern hemisphere—brought together from all parts of the world a large number of geologists, whose eloquent appreciation of the arrangements made for them must have been most gratifying to the organising committee after its two years of labour in carrying through the intricate work of organisation

The experiment of assembling such an international gathering in a country so far removed from the centres of geological progress in Europe and the United States was not viewed without some misgivings Though Nature has lavishly endowed southern Africa with many geological features of exceptional interest and wide significance, besides enriching it with great mineral wealth, the sub continent is essentially a region of wide spaces, requiring a large canvas for their geological portrait, in South Africa, indeed, 'regional' geology seems written in very large letters, so that the visiting geologist needs much time and a longish purse to travel the enormous distances that have to be covered before he can encompass the main designs of the geological structure Moreover, South Africa is a young country in which systematic geological work has been in progress only for a relatively short period, and is being carried on by a comparatively small band of geologists These are some of the difficulties that faced the organising committee when designing the detailed programme

Now that the fifteenth session has passed into history, it is a pleasure (and a relief) to be able to record the complete success of the experiment The total membership was 575 out of which number 300 were present Considering the obvious difficulties and cost involved in participating in the South African meeting, this attendance was very gratifying, specially as it compares favourably with some of the earlier sessions that were held in Europe The 117 delegates who represented geological surveys, museums, scientific societies, and other institutions, included some seventy official delegates of governments, while no fewer than 22 directors of geological surveys were present

Since the geology of South Africa is still relatively little known from an international point of view, the organising committee had designed a series of 22 excursions, covering visits to almost all the most attractive geological areas, as well as introducing the members to all the principal types of mineral deposits, fortunately, the generous support from the South African railway administration, the mining industry and other bodies, allowed the visitors to take part in these excursions in favourable financial and other circumstances The remarkable extent to which members seized these opportunities was certainly a notable feature of the South African meeting, the membership of some of the excursions exceeding a hundred, and many others were fully booked up

The official programme being based on the arrival of the bulk of the Congress at Cape Town before the opening session at Pretoria, two long excursions were provided to demonstrate some of the most important geological features in the Cape Province, such as the structure of the Hex River Mountains, the Karroo geology round Laingsburg, etc, the Kimberley diamond mines and the unique glacial pavements of the Dwyka period near Kimberley, one of these excursions was specially designed for economic geologists and included several days spent in the Witwatersrand goldfields

During the ten days of the session at Pretoria there were several short excursions, all of which were well attended, here the members saw, for example, the beautiful suite of alkaline rock masses near the capital and in the Pilandsberg (Western Transvaal) with its remarkable ring intrusions, and the great opencast workings of the Premier Diamond Mine, visited by 150 members, or the peculiar crater like depression of the Salt Pan in the Bushveld granite north-west of Pretoria, first described by the late Prof E Cohen

After the session at Pretoria there were provided eight long excursions, occupying from three to fourteen days and offering an extensive field of choice from Durban and Port Elizabeth on the east to Windhuk, Luderitzbucht and Tsumeb on the west, and up to Livingstone and Broken Hill in the north, the programme included a visit to the far famed Devil's Kantoor in the great eastern escarpment of the Transvaal Drakensberg, which affords one of the most comprehensive object lessons to be found in the whole of the sub continent for studying the relationship between the interior plateau region and the low lying coastal belt The unique Vredefort Dome with its puzzling tectonics, remarkable overtilting of thousands of feet of the encircling intensity metamorphosed sediments, together with its peculiar ring dykes and startling crush phenomena (profusion of flinty crush rocks), was also included, and gave rise to some interesting discussions in the field The long excursion through Southern Rhodesia to the unique feature of the Great Dyke, etc, and culminating in a visit to the Victoria (Zambezi) Falls, proved of special interest, and nearly a hundred geologists took part in it, it was a happy thought of the Northern Rhodesian Administration to organise a geological tour through that country, so as to enable members of the Congress to see something of its wonderful copper bearing formations that seem destined to develop into one of the most valuable of the Empire's mineral assets Through the hospitality of the Union Minière du Haut Katanga, a special excursion was provided over the remarkable copper fields of the Belgian Congo

Other sections of the official programme took members across the Orange Free State to Durban and into Zululand with its rich cretaceous fauna, to Port Elizabeth, etc, or across South West Africa with its fascinating physiographical problems, etc Another excursion was across the eastern section of the unique Bushveld Complex (including the remarkable tin pipes near Potgietersrust)—embracing an itinerary well away from a railway line under conditions somewhat novel to some of the members—and attracted a very fine membership, including several outstanding workers in magmatic geology Excellent opportunities were offered for seeing the remarkable results of the extreme phases of differentiation in the great norite Lopolith, as illustrated by the chromite and magnetite bands, the anorthosites, etc This itinerary followed very closely that of the Shaler Memorial Expedition of 1922 (under the leadership of Prof R A Daly)

SECTIONAL DISCUSSIONS

The subjects put forward for discussion were chosen, so far as possible, with reference to phenomena of special importance in the geology of South Africa magmatic differentiation, pre Pleistocene Glacial periods, the Karroo System, its stratigraphy, palæontology, and world distribution, the genesis of petroleum, the geological work of micro organisms There was also a general section Having come so far to attend the Congress, the visiting geologists were eager to see as much as possible of South African

geology, so that the excursions were naturally a great attraction to most members, hence it is not surprising that only some seventy papers were communicated, many of these, however, are valuable contributions to matters of wide interest

In the Section dealing with Magmatic Differentiation there were (among other contributions) two papers by Dr E Reuning on "The Differentiation of Karroo Eruptives in South West Africa" and on "Differentiation of South African Rock Magmas", and another by Prof P Niggli on "Some Principles in the Problem of Magmatic Differentiation" The proceedings of this section were most instructive, and very much apropos, in view of the splendid display of magmatic phenomena on the long excursion across the Bushveld, and on that to the Rustenburg Platinum Fields

The remarkable Pre Pleistocene Glacial Deposits of South Africa were discussed in three most useful summaries by Dr A W Rogers (Pretoria), Dr S H Haughton (Cape Town), and Dr A L du Toit (Kimberley) Prof Gortani (Bologna) had a paper on "Continental Drift and Glacial Epochs", while the late Palæozoic tillites in Central Asia and the northernmost Ural were dealt with by E Norin and H G Backlund

A large number of contributions were to the subject of the Karroo System both in its stratigraphical and palæontological aspects, these add much of importance to our knowledge of that system, more especially in its African developments H Besairie ("The Stratigraphy of the Karroo System in Madagascar"), F Dixey ("The Karroo of the Lower Shire Zambezi Region"), A B Walkom ("A Comparison of the Fossil Floras of Australia with those of South Africa"), P Fourmarier ("Karroo System of Belgian Congo"), F Mouta and A Borges ("Sur l Existence et la Distribution du Karroo dans l'Angola"), G Stefanini ("On the Sequence and Age of the Lugh Sandstones, Italian Somaliland") and F P Mennell (Bulawayo), ("The Karroo System in East and Central Africa") are some of the principal contributions

The Rift Valleys Section attracted much interest and brought out some good discussions One of the more notable contributions is by E J Wayland (Entebbe), "The Albertine Rift, a Compressional Phenomena", in which a tectonic parallel is drawn between Lake Albert and the Dead Sea Prof H Cloos (Bonn) gave a thoughtful address on "Tectonic Experiments and the Origin of Fracture Zones", there were also papers by E Seidl (Berlin), J J Pannekoek van Rheden (Haarlem), D Johnson (New York), etc

A great variety of subjects were presented in the General Section, for example, Prof G Gurich (Hamburg) directed attention to the traces of the oldest organisms hitherto found in South Africa, Dr N R Junner (Freetown) gave a useful account of the norite of Sierra Leone, M H J Schuiling (Panda) read a valuable paper on the Kambove Copper Mine (Katanga), while Dr O Pratje (Königsberg) delivered an illustrated address on the results of the geological investigation of the South Atlantic Ocean Other attractive papers were by Prof A Demay (St Etienne) on Hercynian tectonics in France, C Freire d'Andrade (Lourenço Marques) on Portuguese East Africa, P Kovaloff (Johannesburg) on the beryl finds in Namaqualand, A O D Mogg (Pretoria), who discussed the connexion between flora and geology in the Vryburg district, etc

The great interest aroused by recent advances in geophysical methods of prospecting led to a special meeting for this branch of geology, in which Dr J G Sineriz (Spain), Dr D Mushketov (U S S R), and Dr J W Evans (Great Britain) took a prominent part

Following the example set at previous meetings—which resulted in valuable compilations on the world's supplies of, for example, pyrites, coal, iron, etc, it had been decided to survey the "Gold Resources of the World", a subject of outstanding international and economic importance, and specially worthy of being handled by the Congress while meeting in the greatest gold producing country of the world The proposal was initiated by means of a special invitation over the signature of the Prime Minister of the Union, when the session opened, reports had been received from 45 different governments The publication of this volume will be welcomed by many students

International Commissions of the Congress

During the session a series of meetings were held in connexion with the various International Commissions, the work of which is an important feature in the life of the Congress In the end, several commissions had to be reconstituted, one new commission and one sub commission were established, while of the previous bodies, one (iron ores) was dissolved, so that the Congress now has the following commissions Prix Spendiaroff (awarded to Dr L T Nel, geologist on the Geological Survey of the Union of South Africa), Palæontologia Universalis, Lexicon de Stratigraphie, Glaciers, L'Homme Fossile, Croute Terrestre, Géophysique et Géothermique, Carte de l'Europe, Carte de la Terre, Distribution of the Karroo (Gondwana) System, to these was added the sub commission of African Surveys The Council was fortunate in securing an excellent and thoroughly representative membership for most of these commissions

Since the last meeting of the Congress, in Spain during 1926, much useful work has been accomplished by the two map commissions, under the chairmanship of Dr P Krusch, president of the Geological Survey of Prussia The one for the map of Europe on the scale of 1 1,500,000 was founded at Bologna in 1881 and shortly after the Toronto congress in 1913 completed its task by publishing the last sheet, and the preparation of a new edition was afterwards decided upon The indispensable preliminary work of agreeing upon the best colour scheme was completed at a meeting of the Commission held in Berlin last February, and during the South African meeting Dr W Schriel (general secretary of the Commission) exhibited two advance sheets of the new edition, in their original form, the great beauty of the colour scheme and the excellence of the draughtsmanship were much admired by many members One section of the new edition is ready for the press and further sections are expected to appear at the rate of two in each year

The publication of the International Map of the World on the scale of 1 5,000,000 was decided upon at the Stockholm congress in 1910, and the colour scheme drafted at the Berlin meeting referred to, two sections embracing the Union of South Africa being afterwards prepared, they were presented at the Pretoria meeting For the next congress it was agreed to prepare a few North American sections

The final editing is to be done at Berlin (as was formerly the case) in order to secure uniformity of issue, for which purpose a special bureau has been established at Berlin Dr P Krusch (chairman of both map commissions) was able to announce the fortunate circumstance that the means for the printing of both maps have been made available by Prussia, so that in due course the sheets will be obtainable through the Geological Survey of that country

The keen interest shown in the stratigraphy, palæontology and world distribution of the Karroo System which constituted one of the sections of the Congress (as explained above) culminated in the establishment of a new Commission on the Correlation of the Karroo (Gondwana) System, the proposal emanated from Dr S H Haughton (Cape Town)—an outstanding authority on the Karroo System—strongly supported by Prof G Stefanini (Bologna), Dr L L Fermor (Calcutta), Dr D Mushketov (Leningrad) and others The Commission has Dr A W Rogers as chairman and includes the directors of geological surveys (or government geologists) of all countries concerned, together with representatives for Italy Australia, etc with Dr S H Haughton as its secretary, so that one may look to much useful work before long

The presence at the session of representatives of practically every country maintaining some form of geological survey in Africa, led to a strong desire to make use of this unique opportunity of establishing closer co operation between African surveys A number of well attended meetings were followed by the formation of a Sub Commission of African Surveys, on the initiation of Dr G W Grabham (Khartoum) supported by Dr A L du Toit (Kimberley) One of the chief aims of this Commission is "to promote co operation between all Governments in Africa with a view to prosecuting geological mapping of the Continent" Its president is Prof G A F Molengraaff (Delft), whose name is so well known to all students of South African geology, while M Jean Lombard (Brazzaville) is its secretary the membership includes all the chiefs of official geological surveys and those of unofficial geological surveys or their representatives as well as Dr J W Evans It is proposed to issue as soon as possible a "Handbook of the Geology of Central Africa" and to attack the following problems Rift valleys, glacial periods, thrusts, changes of climate, nature of great batholiths, modern sedimentation in connexion with earth movements When one realises the many centres at which geological work is being carried on in Africa practically in watertight compartments, one may look for important results from this new body, which was designated a *sub* commission in order to emphasise the facts that its work is not intended to interfere with that of any commission concerned with the map of Africa

The general meeting of the Congress also asked the Union Government to preserve as a kind of 'Glacial National Park" the beautiful and unique striated pavements near Kimberley which aroused great enthusiasm among the members, and urged the publication of the Contour Map of the Union on the scale of 1 1,000 000 prepared by Mr E H Banks, Cartographer to the Geological Survey The hand coloured original was displayed at the Congress and beyond doubt forms an admirable 'pendant' to the geological map recently published on the same scale

GENERAL IMPRESSIONS

The almost simultaneous meeting of the British Association at Johannesburg had attracted a vast gathering of overseas workers and though it was impossible to secure a fusion between its Geological Section and the Congress a large measure of hearty co operation was possible which the Geological Society of South Africa did much to secure

For the venue of the sixteenth session, the Council had received an invitation from the Comité Géologique in Leningrad, presented by Dr D Mushketov, and another from the United States, presented by Prof C P Berkey Though many members would have welcomed the opportunity of visiting Russia, the general meeting decided in favour of the United States, where the next Congress is to assemble probably in 1932

Surveying the activities of the last session as a whole, one feels that the traditions of this international movement were worthily maintained, both as regards the organisation and general arrangements for seeing the main geological features of the country, and in the contributions made to geological science There can be no doubt that the great success of the excursions the keen interest taken by the visitors in all they saw, and their intense energy in collecting from the crust of the earth, will in due course result in a substantial enrichment of South African literature Certainly the personal contact with so many leaders of geological thought under conditions of perfect international harmony was (and will continue) a splendid stimulus to the little handful of local geologists whose work has to be pursued more or less in the shadows of the light that illuminates the progress of geology elsewhere

A L H

Properties of Water and Steam

THE sixteenth Thomas Hawksley Lecture of the Institution of Mechanical Engineers, delivered by Prof H L Callendar on Nov 1, and entitled "Critical Relations between Water and Steam," takes the form of a very interesting historical survey of the development of knowledge of the physical properties of water and steam Actual measurements of heat quantities and densities at high pressures and temperatures are so difficult and expensive to obtain that this data has always been and still is incomplete, and the physicists' attempts to bridge the gaps by establishing theoretical relations agreeing with experimental results, are described in chronological order

The theory of the continuity of state, which assumes that "liquid and vapour are merely widely separated forms of the same condition of matter, and differ only in density", was so ingenious and attractive that it held the field for sixty years and received a tremendous amount of attention The salient points in its development are, therefore, illustrated, but finally the assumption of identity of molecular structure of water and water vapour was generally abandoned

Recent researches on the structure of crystals suggest the co aggregation theory The density of steam at low pressures shows that the great majority of the molecules are single H_2O molecules, but there is no doubt that steam contains a proportion of complex molecules which increases with the density, and this would account for the increasing defect of volume from the ideal with increasing pressure The latent heat of co aggregation of the complex molecules also explains the increasing defect of total heat with increase of density As regards the water, the co aggregation of the molecules appears to be a higher degree of multiplicity, but is apparently so mobile and irregular as to make analysis almost hopeless However, the relative positions and distances apart of the atoms of crystalline solids, such as ice, have been determined recently with great accuracy, and this shows that their arrangement depends in many important cases on the ionic group formation known to exist in the liquid, rather than on the chemical formula for the molecule in the vapour state

In this connexion illustrations are given of Sir William Bragg's model of the crystal structure of ice, and the continuous nature of the network is described It is shown that there is no trace of the original vapour molecule, except that the total number of hydrogen

atoms in the crystal is exactly twice that of the oxygen atoms The complete hexagonal molecule existing in the ice is one of the most probable types existing in the liquid, but there must be many others of greater degrees of complexity, and the reduction of the proportions of complex molecules with increase of temperature helps to explain the high specific heat of water and the reduction of the latent heat This proportion becoming insufficient to maintain a continuous network would explain the vanishing of the surface tension at the critical point The vapour would probably contain molecules of a small degree of complexity, but they would doubtless behave as gas molecules, having the same kinetic energy but lower velocity on account of their greater masses This all indicates that the same type of equation cannot satisfactorily represent the behaviour both of the liquid and the vapour

Based on this theory the following modified Joule-Thomson equation is adopted

$$V - b = RT/P - C,$$

in which C represents the defect due to co aggregation The heat of water in equilibrium with saturated steam can be represented by

$$h = So\ (t - 32) + vL\ (V - v),$$

which equation has been verified by direct measurement of h up to 3800 lb pressure These two equations combined enable the saturation pressures to be calculated by Rankine's method, and give good agreement with observation up to 400° F with C a function of T only For higher temperatures it will be possible, by making C a function of P as well as of T, to obtain good agreement over the whole range, 32° to 717° F

Densities have been determined by heating suitable quantities of water in sealed quartz glass tubes The density of the liquid was determined by observing its expansion up to the temperature at which the meniscous vanished, which was found to be 705 2° F The density of the vapour was determined by using smaller quantities of water and observing the temperature at which the liquid was completely evaporated The densities did not become equal at the temperature at which the meniscus vanished but were in the ratio of 5 to 3

A method of determining the total heats in the critical region gave values consistent to 0 1° F and corresponded remarkably well with the density measurements The latent heat at 705 2° F, where the meniscus vanished, was found to be 130 B T U per lb and the saturation lines for liquid and vapour do not meet at 705 2° F but at 717° F and at a pressure of 3650 lb, while the density curves from the quartz tube experiments do not meet at 705 2° F in a parabola but at about 717° F when extrapolated

In discussing a diagram of total heat plotted to a base of log pressure, a statement is made which suggests that with steam at an initial temperature of 670° F a higher thermal efficiency is obtained with 500 lb per sq in than with 1000 lb per sq in initial pressure The reference is to the dry region, and presumably therefore only a small range of expansion is considered However, if the comparison is made on a practical basis, with expansion to a common final pressure of such value as obtains in an ordinary steam power plant, the higher initial pressure produces a considerable gain in thermal efficiency, because not only is the available energy due to adiabatic expansion greater, but also the heat input is less These facts are quite easily established by calculating the required values from any published tables of properties of steam, including those published by Callendar himself It is unfortunate that this wrong impression should be created by a statement of so great an authority on the subject, particularly at a time when progressive engineers everywhere are fighting against conservatism in their effort to introduce higher initial steam pressures into large steam power plants with the object of improving the overall efficiency

University and Educational Intelligence

EDINBURGH —The degree of D Sc has been conferred upon Prof R S Adamson for his thesis on studies in plant ecology and in plant anatomy, and on Robert Neil Chrystal for his thesis on *Sirex* and the *Ibalia* parasite—the biology and post embryonic development of *Ibalia leucospoides*

ST ANDREWS —The Court has approved the nomination of Dr E T Copson, formerly scholar of St John's College, Oxford, lecturer in mathematics in the University of Edinburgh and honorary secretary of the Edinburgh Mathematical Society, as lecturer in mathematics and applied mathematics in succession to Dr William Saddler, who has recently been appointed to the chair of mathematics at Christchurch, in the University of New Zealand

MEMORANDA have been issued regarding the various Commonwealth Fund Fellowships available in 1930 The fellowships are open to British graduate students and tenable in American universities As many as thirty fellowships, tenable for two years, are available to graduates of British universities who are domiciled in the British Isles, are of British descent, unmarried, and less than thirty years of age Not more than five fellowships are also available on similar terms to graduates from any of the British Dominions A further class of fellowships, limited to three a year, is offered to overseas government officers in the actual employ of the Government of Great Britain, India, or any of the Dominions, the age limit for these fellowships is thirty five years and they may be married Every fellow appointed has to submit a course of study or research, and is expected to travel about the United States in connexion with his work There is no fixed emolument, but each fellowship is estimated to cost the Fund about £600 a year Particulars and application forms, to be returned by Feb 10, can be obtained from the secretary, Mr R H Simpson, Commonwealth Fund Fellowships, 50 Russell Square, London, W C 1

THROUGH the generosity of Mr P F Holmes and Mr D M Henshaw of Huddersfield, there has been placed in the hands of the Institution of Gas Engineers a fund for the purpose of endowing a scholarship to be called the William Cartwright Holmes Scholarship, which shall be tenable at the University of Leeds by a student taking a course in preparation for a responsible position as a gas engineer The scholarship is of the value of £150 per annum for three or four years The donors of the scholarship state that "their first desire was to perpetuate the name of William Cartwright Holmes, and secondly to show appreciation of the training obtained by students of Gas Engineering at Leeds University and of the valuable research work done in the Department of Coal Gas and Fuel Industries" The foundation of such a scholarship is a very practical means of assisting to meet the national need at the present time for trained fuel technologists which was stressed by the National Fuel and Power Committee in its recent report and by Prof J. W Cobb in his last report as Livesey professor of the Department of Coal Gas and Fuel Industries in the University of Leeds

Historic Natural Events

Jan 12, 1914 Eruption of Sakura-jima —A violent eruption occurred in the island volcano of Sakura jima in south Japan It was preceded by many tremors on Jan 11, and these led the authorities to order the removal of the inhabitants, and all of them (more than 23,000 in number) were saved Lava flowing down the east side filled up the narrow strait and converted Sakura jima into a peninsula The total volume of ashes and lava ejected was estimated at one half a cubic mile New surveys showed that most of the volcano was uplifted, in one place by 41 feet Outside the island, the ground was depressed by so much as 20 inches within an irregular circle about 28 miles in diameter

Jan 14, 1716 High Tide during Frost Fair —The winter of 1715–16 was very cold in England and over the whole of Europe At Paris the thermometer fell to -4° F on Jan 22 A fair, with booths and printing presses, was erected on the frozen Thames, on Jan 14 there was an uncommonly high spring tide, which raised the ice fourteen feet without interrupting the progress of the fair

Jan 15, 1662 Mild Winter —Under this date Samuel Pepys records in his diary "It is a fast day ordered by the Parliament, to pray for more season able weather, it having hitherto been summer weather, that is, both as to warmth and every other thing, just as if it were the middle of May or June, which do threaten a plague (as all men think) to follow"

Jan 16, 1362 Gale —A gale began about the time of evensong and continued for six or seven days in the south of England, stronger than had been known for many years It blew down towers, steeples, houses and chimneys, and even the buildings that were not overthrown were rendered unsafe It was followed by a very wet season in summer and harvest

Jan 16, 1614 Frost —It is recorded in Drake's "Eboracum" that on Jan 16 "it began to snow and freeze, and so by intervals snowing without any thaw till the 7th of March following, at which time was such a heavy snow upon the earth as was not re membered by any man then living It pleased God that at the thaw fell very little rain, nevertheless the flood was so great that the Ouze ran down North Street and Skeldergate with such violence as to force all the inhabitants of those streets to leave their houses Ten days this inundation continued at the height and many bridges were broken down by it in the country, and much land overflown"

Jan 17, 1830 Severe Winter —On the continent of Europe the winter of 1829–30 was one of the most rigorous known in history On Jan 17 the thermo meter at Paris fell to 1° F and public 'warmers' were established in the streets In Switzerland instead of snow, small compact crystals of ice fell, as in polar regions In Normandy the snow was more than six feet deep, and many wood gatherers were lost The frost was especially severe in Spain, where communica tions were interrupted, many lives were lost, and many thousands of cattle Bands of wolves, driven from the mountains by the snow, caused great ravages among the herds and killed many people In England this winter was not especially severe

Jan 17, 1881 Low Temperature in Britain —On Jan 7–26 severe frost prevailed over the whole of Great Britain and Ireland, unequalled since the winter of 1814 The lowest temperatures occurred on Jan 17, when the thermometer fell below zero over the south of Scotland and the north of England, reach ing -22° F at Blackadder (Berwickshire), -16° at Kelso, -15° at Stobo, and -11° at Lauder, all in the valley of the Tweed Again on Jan 26 a temperature of -16° F was recorded at Blackadder, but there is some doubt whether the exposure of the thermometer at this station was satisfactory These low tempera tures all occurred during a period of light northerly winds

Jan 18, 1881 Great Snowstorm —A barometric depression, which originated off the east coast of the United States on Jan 10, crossed the Atlantic in a general easterly direction, and on the evening of Jan 17 it traversed the Bay of Biscay At 8 A M on Jan 18 it was very intense and lay near the Channel Islands, and throughout that day it moved slowly and rather irregularly over the central parts of the English Channel before passing away to Germany on Jan 19 Over the Midlands, east and south east England, the most violent easterly gale on record blew throughout Jan 18, the velocity at Yarmouth being 73 miles an hour for fifteen minutes between 3 and 4 P M The gale was accompanied by heavy snowstorms over nearly the whole of England, and in many places the railway lines were completely blocked for many hours In London the snowstorm was the worst within living memory, and owing to the high wind curious drifting effects were experienced, some streets being perfectly clear on one side but heavily piled with snow on the other The fall was especially heavy in the Isle of Wight, where it was quickly followed by a second on Jan 20, in Cowes there were drifts in the streets 12 feet deep

Jan 18, 1926 Hurricane —A very violent hurri cane ravaged all the Canary Isles Torrential rain overflowed the water courses and a great deal of damage was done by rain and wind At Las Palmas scarcely a house was left standing

Societies and Academies

PARIS

Academy of Sciences, Nov 25 —**L Mangin** Notice of Sir Ray Lankester, foreign associate of the Academy —**Gabriel Bertrand** and **L Silberstein** The estimation of sulphur and phosphorus in plants It was proved that the proportion of sulphur remaining in the ash is always less than that which exists in the plant, the losses ranging from 44 per cent to 76 per cent There is also a loss of phosphorus during cal cination to ash, but the losses are much less from 0 2 per cent to 7 per cent of the amount present —**J A Le Bel** The sparks which are emitted by stalactites when violently struck with a steel tool It was at first supposed that these sparks were due to the presence of quartz particles in the rock, but it was later proved that no hard particles were present The phenomenon is probably due to triboluminescence —**G Friedel** and **V Maikowsky** Temperature measure ments in borings The thermometer consists of an ungraduated bulb with capillary tube, with the upper end open and ground to a plane face making an angle of 45° with the tube The actual temperature at which the tube is exactly full, corresponding to the temperature attained in the boring, is easily deter mined in the laboratory —Ernest Esclangon was elected a member of the Section of Astronomy in the place of the late P Puiseux —**Herbert Ory** The ex traction of roots —**H Milloux** Some properties of meromorph and holomorph functions —**Joseph Pérès** Some results concerning the stability or the regularity of the movement of a viscous liquid —**G P Arcay** Contribution to the experimental study of the de formation of the flat spiral From the experimental evidence given in the paper, it is concluded that the static deformation and the kinematic deformation of

the flat spiral, corresponding to the same position of the balance wheel, are in all cases identical Consequently, it is legitimate to utilise the method of static deformations as a method of experimental control — **Louis Hirschauer** and **Augustin Talon** The auto railroad proposition for rapid transport with high duty —**G Bruhat** and **R Legris** The rotatory dispersion of tartaric acid and of the alkaline tartrates in aqueous solution —**Jean Thibaud** and **Jean J Trillat** The effects of filtration of the general radiation on the X ray diagrams of liquids The determination of absorption coefficients The existence of a secondary diffraction ring due to the general radiation, shows the necessity, in researches on the molecular structure of substances radiographed in thicknesses of several millimetres, of precautions against the formation of the secondary ring For this, either the radiation may be made monochromatic by reflection from a crystal, or an absorbing sector of aluminium may be placed near the film —**M Bourguel** and **Mlle V Gredy** The mechanism of catalytic hydrogenation Whatever may be the mode of working, the initial velocity of hydrogenation is, for a given substance, independent of the weight of material to be hydrogenated The activity of the catalyst is a diminishing function of the initial concentration The results can be best explained by the assumption of an initial action of the hydrogen on the metal (palladium) —**L Meunier** and **K Le Vlet** The hydrophil properties of collagen Any substance capable of lowering irreversibly the capacity of the collagen for swelling is a tanning substance, and its astringency is measured by the intensity of this lowering —**Jacques Bardet** and **Arakel Tchakirian** Some combinations of germanium oxide and oxalic acid Experimental evidence is given for the existence of a complex germano oxalic acid it was not possible to isolate a definite compound, but $H_2Ge(C_2O_4)_3$ is probably present in the solution —**Mme Ramart-Lucas** and **F Salmon-Legagneur** Stability in absorption spectra The absorption in the ultra violet of the dibasic acids of the fatty series - **P Mondain-Monval** and **R Quanquin** The temperature of spontaneous inflammation of gaseous mixtures of air and saturated hydrocarbons The influence of the pressure and of preliminary heating Supplementing earlier work in which the oxidation was carried out under high pressures, experiments at the ordinary pressure are described With pentane, aldehydes were detected at 200° C, and were produced in quantity at 325° C The presence of formaldehyde, acetaldehyde, butyraldehyde, and fatty acids was proved —**G Dupont** and **J Lévy** The autoxidation of abietic acid The action of catalysts In a previous communication the autoxidation of abietic acid was shown to be a typical example of autocatalysis The influence of the addition of catalysts has now been studied cobalt abietate proved to be the most active positive catalyst **Lucien Dupont** : The action of caustic alkalis at high temperatures on albumenoids The proportions of oxalic, benzoic, and various fatty acids obtained by potash fusion at 325° C are given for gelatine and for egg albumen —**J Grard** Some reactions of propargyl acetal —**A Guyot** and **M Fournier** A new general method for the preparation of primary and secondary amines The reaction proposed is $R\ CH_2OH + R'NH_2 = R\ CH_2\ NHR' + H_2O$ This takes place in an autoclave in the presence of reduced nickel at temperatures from 150° to 190° C If ammonia is used in place of the primary amine, both primary and secondary amine are formed in proportions depending on the temperature The yields are high and the method appears to be general —**D Ivanoff** Some properties of the true mixed organo magnesium carbonates —**L Royer** New observations on the asymmetry of the corrosion figures obtained by an active isotropic liquid —**E Raguin** Subdivisions of the layer of bright schists in Haute Maurienne — **Yang Kieh** The massif of crushed pegmatite situated at the southern edge of the geological sheet of Aigurande (scale 1/80,000) —**Marcel Thoral** Palæontological discoveries in the Cambrian and Silurian of the mountains of Lacaune to the north of the Montagne Noire —**J Thoulet** Isothermal oceanic liquid cones of whirling —**R Combes** and **M Piney** Proteolysis and proteogenesis in ligneous plants during the summer and autumn —**A Orékhoff** The alkaloids of *Anabasis aphylla* This plant, which grows wild in Turkestan and Transcaucasia, is known to be very poisonous A new base, anabasine, $C_{10}H_{14}N_2$, has been extracted from the dry plant and prepared pure Other bases, not so far obtained pure enough for analysis, are also present —**G Nicolas** and **Mlle Aggéry** A new example of generalised bacterial infection in plants —**J André Thomas** The phenomena of modification of toxic attack of the Convoluta as a function of their grouping —**Jean Saidman** Radiotherapy of aerophagy

Dec 2 —**Marcel Brillouin** The dynamical tides of an ocean comprised between two parallels Law of depth in latitude and longitude The organisation of the calculations —**Léon Guillet** and **Marcel Ballay** The corrosion of steels after cementation or formation of nitride —Charles Nicolle was elected a non resident member in the place of the late Ch Depéret -**O Borůvka** Projectively deformable surfaces which admit a group of ∞' projective transformations in themselves — **Fatou** A criterion of stability —**Nicolas Théodoresco** The application of a formula generalising the Cauchy integral to a hydrodynamical question — **Jean Courrégelongue** The existence of two families of vortices behind immerged solids —**L Ravier** A general formula for the calculation of the thrust of the soil —**Paul Woog** The extension of lubricants on solid surfaces Molecular influences The rôle of photolysis —**Marcel Chopin** The flow of gas through an orifice in a thin wall at variable temperatures —**P Swings** The resonance series of sulphur vapour —**L Goldstein** The relativist treatment of the problem of several bodies —**Frédéric Joliot** The electrochemical properties of polonium — **Mlle Dorabialska** The heat evolved by polonium The amount of heat evolved, reduced to a quantity of polonium in radioactive equilibrium with 1 gram of radium, was found to be 24 calories per hour This figure is given with reserve, since it is distinctly below that deduced from the heat measured for radium and its derivatives —**Maurice Lecat** The prediction of binary azeotropism —**Roger Lyon, G Fron,** and **Fournier** The influence of artificial ageing on the mechanical properties of wood Data are given showing the effects of mild and drastic treatment with ozone on wood —**Raymond Hocart** and **Jacques de Lapparent** The bœhmite of bauxites The identity of Bœhm's 'bauxite' with bœhmite was proved by the application of Debye and Scherrer's method — **Constant Ktenas** New researches on the petrochemical characters of the caldeira of Santorin — **Maurice Couvreur** Note on the conformal and non conformal siliceous epigeny of the testa of Lamellibranchs —**H de Böckh** and **P Viennot** The geology of Iraq —**Raymond Furon** The position of the palæozoic grits to the north of the middle Niger (French Sudan) —**Y Milon** The presence of glauconite in the Pliocene sands of Brittany —**G Pontier** and **R Anthony** The presence of four upper incisors in the *Mastodon (Tetrabelodon) turicensis* —**Georges Malençon** The first stages of germination of the

spores of the genus *Elaphomyces* —**Paul Guérin** The proportion of hydrocyanic acid in the genus *Lotus* Determinations of the amount of hydrocyanic acid in twelve species of *Lotus* have been made The proportions found depend on the time of year the specimens were collected, and also on the climate —**Georges Truffaut and I Pastac** The chemotherapy of plant diseases by organic colouring matters It has been proved that certain colouring matters, innocuous to the higher animals, can prevent the development of moulds (*Rhizopus nigricans, Penicillium glaucum*) The treatment has been successfully applied to diseases of the vine and of wheat —**Laurent Raybaud** The action of germinated seeds in feeding Sterile germinated grain has marked beneficial effects when taken with other food It has proved especially valuable with rickets in children —**Jean Piveteau** A new type of fossil fish from the north of Madagascar —**Emile F Terroine and Mlle Thérèse Reichert** The action of mineral substances on endogenous nitrogen metabolism —**P Vayssière** The migratory Acridians in French Africa during the year 1929 —**L Lavauden** The wild cat of Corsica —**Ch Pérard** The caoutchouc conger In the fish market at Paris congers are occasionally sold the flesh of which differs from that of the normal conger eel, resembling india rubber hence its name Analyses of the flesh of the abnormal eel showed that its consistency was due to a reduction in fat, 0 4 per cent instead of 9 per cent, and this was shown to be due to a concentration of the fat in the ovary —**Marc de Larambergue** Cytological study of autofertilisation in *Limnæa auricularia* —**W Arciszewski and W Kopaczewski** The buffer power of serum Human serum can be treated with either acid or base to a concentration of about $M/2000$ without change in the concentration in hydrogen ions or hydroxyl ions This buffer action extends to other ions The serum offers resistance to any change in its surface tension —**L Marchlewski** Researches on phylloerythrin Phylloerythrin is a product of metabolism of chlorophyll and is identical with the bilipurpurin of Lobisch Its composition is represented by $C_{33}H_{34}N_4O_3$ and when crystallised from chloroform it gives crystals containing one molecule of chloroform to two molecules of phylloerythrin —**Maurice Piettre** The influence of neutral salts on the separation of proteins by the acetone method The effect of salts (magnesium sulphate) is very important in the separation of proteins by the acetone method Small quantities of neutral salts prevent, or at least render difficult, the isolation of the proteins of the globulin group —**Marage** The causes and consequences of the deafness of Beethoven —**Ch Champy and M Heitz-Boyer** The mechanism of the action of the electrical knife with high frequency Thermal and mechanical effects of high frequency currents on the tissues

Diary of Societies

FRIDAY JANUARY 10

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 3 30 —H G Watkins By Canoe and Dog Sledge in Labrador (Christmas Lectures) (2)

ROYAL SOCIETY OF ARTS (Indian Section) at 4 30 —Sir Basil P Blackett The Economic Progress of India

ROYAL ASTRONOMICAL SOCIETY, at 5 —E A Kreiken The Frequency of Double Stars of Different Spectral Types and Absolute Magnitudes —J Jackson The Shortt Clocks of the Royal Observatory Greenwich with Special Reference to the Effect of Variation in Arc —H Jones Deviations from Boyle's Law in Stellar Interiors

MALACOLOGICAL SOCIETY OF LONDON (in Zoological Department, University College), at 6

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute, Newcastle upon Tyne) at 6 —I C Burrill Design and Construction of the Rail car carrying Steamship *Seatrain*

SOCIETY OF CHEMICAL INDUSTRY (Manchester Section) (at Engineers Club Manchester) at 7 —Dr E K Rideal Some Aspects of Surface Chemistry and their Industrial Implications

INSTITUTION OF ELECTRICAL ENGINEERS (North Western Centre) (at Free Trade Hall Manchester), at 7 —Capt P P Eckersley Broadcasting by Electric Waves (Faraday Lecture)

OIL AND COLOUR CHEMISTS ASSOCIATION (Manchester Section) (at Milton Hall Manchester) at 7 —Prof T P Hilditch Recent Research on Fats bearing upon the Drying of Oils in Paint and Varnish

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (at Cardiff Technical College) at 7 15 —E H Williams Graphitic Lubricants

JUNIOR INSTITUTION OF ENGINEERS, at 7 30 —H J N Riddle The Track Circuit in Railway Signalling

GEOLOGISTS ASSOCIATION (at University College), at 7 30 —J Pringle The Geology of Ramsey Island (Pem) *Papers to be taken as read* —The Palæobotany of the Kent Coalfield Dr R Crookall and J Pringle The Preparation of Thin Sections of Friable and Weathered Materials by Impregnation with Synthetic Resins R J Schaffer and P Hirst

SOCIETY OF CHEMICAL INDUSTRY (Chemical Engineering Group) (at Burlington House) at 8 —J R Booer Autogenous Welding in Chemical Works

PHILOLOGICAL SOCIETY (at University College), at 8 —G G Loane Notes on N E D

ROYAL SOCIETY OF MEDICINE (Ophthalmology Section) at 8 30 —Dr F W Edridge Green The Influence of the Parafoveal on the Foveal Region of the Retina —J D N Cardell Krukenberg's Spindles —E Wolff A Microphthalmic Family

SATURDAY JANUARY 11

BRITISH ASSOCIATION OF MANAGERS OF TEXTILE WORKS (at Manchester Athenæum) at 6 30 —J R Wollaston Recent Developments in Steam Generation

MONDAY JANUARY 13

ROYAL SOCIETY OF EDINBURGH, at 4 30 —G Bond The Occurrence of Cell Division in the Endodermis —D Catcheside Chromosome Linkage and Syndesis in *Œnothera* —D R R Burt A Case of Intersexuality in *Bos indicus*, with a Theory of the Significance of the Genetic Male Intersex

INSTITUTE OF TRANSPORT (at Institution of Electrical Engineers) at 5 30 —A Davies The Co ordination of Transport.

INSTITUTION OF AUTOMOBILE ENGINEERS (Birmingham Centre) (at Queen's Hotel, Birmingham), at 7 —H K Whitehorn Petrol Electric Vehicle Characteristics

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—A. Morgan and others: Discussion on Efficiency.
INSTITUTION OF ELECTRICAL ENGINEERS (North Eastern Centre) (at Armstrong College, Newcastle-upon-Tyne), at 7.—H. W. Taylor: Voltage Control of Large Alternators.
INSTITUTION OF HEATING AND VENTILATING ENGINEERS (Associate Members and Graduates Section) (at Borough Polytechnic), at 7.—H. A. Leadbeater: Oil versus Solid Fuels.
CERAMIC SOCIETY (at North Staffordshire Technical College, Stoke-on-Trent), at 7.30.—J. W. Thompson: A New Method of Decoration of Glazed Tiles.—N. D. Wood: Research into the 'Buckling' of Floor Tiles.—R. M. Colles: Heat Losses from Exposed Surfaces.
INSTITUTE OF METALS (Scottish Local Section) (at 39 Elmbank Crescent, Glasgow), at 7.30.—A. Wragg: Extrusion, and a Consideration of some of the Physical Properties affecting the Production of Rods, Tubes, and Sections by this Process.
ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—Dr. T. F. Chipp: Forests and Plants of the Anglo-Egyptian Sudan.
INSTITUTE OF BREWING (London Section) (at Charing Cross Hotel).—I. Stewart: Malting Barleys of 1929.

TUESDAY, JANUARY 14.

SOCIETY FOR THE STUDY OF INEBRIETY (at Medical Society of London), at 4.—Dr. W. Brown and others: Discussion on The Rôle of Psychotherapy in the Prevention and Treatment of Alcoholism and other Drug Addictions.
MINERALOGICAL SOCIETY, at 5.30.—Sir Douglas Mawson: On the Occurrence of Potassium Nitrate near Goyder's Pass, McDonnell Ranges, Central Australia.—Dr. L. T. Nell: On a New Occurrence of Yunyite near Postmasburg, South Africa.—F. N. Ashcroft: Exhibiting Minerals from Broken Hill, Rhodesia, and Other Localities.—W. Campbell Smith: Exhibiting Specimens and Photomicrographs of Volcanic Rocks from Kenya Colony.
INSTITUTION OF PETROLEUM TECHNOLOGISTS (at Royal Society of Arts), at 5.30.—A. A. Ashworth: Efficiency in the Distillation of Light Oils from Crude Oil.
INSTITUTION OF CIVIL ENGINEERS, at 6.—A. E. L. Chorlton: Railway Traction by Oil Engines.
INSTITUTE OF MARINE ENGINEERS, at 6.30.—Eng. Rear-Adml. W. M. Whayman: Water Tube Boilers for Merchant Ships.
INSTITUTION OF ELECTRICAL ENGINEERS (North Midland Centre) (at Hotel Metropole, Leeds), at 7.—I. Scott Mackenzie and others: Discussion on Colliery Electrification.
INSTITUTION OF ELECTRICAL ENGINEERS (Scottish Centre) (at North British Station Hotel, Edinburgh), at 7.—Lt.-Col. S. E. Monkhouse and L. C. Grant: The Heating of Buildings Electrically by means of Thermal Storage.
MANCHESTER ATHENÆUM TEXTILE SOCIETY (at Manchester), at 7.—H. Keat: Insurance of Goods against Marine Risks.
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—I. M. Thomson: The Bittern and its Neighbours.
BURNLEY TEXTILE SOCIETY (at Burnley), at 7.15.—J. Leigh: Ropes and Rope Driving.
INSTITUTION OF AUTOMOBILE ENGINEERS (Coventry Centre) (at King's Head Hotel, Coventry), at 7.30.—J. B. Hoblyn: Aluminium Alloys from the Users' Point of View.
INSTITUTE OF METALS (North East Coast Local Section) (at Armstrong College, Newcastle-upon-Tyne), at 7.30.—I. Wright: Chromium Plating.
QUEKETT MICROSCOPICAL CLUB (at 11 Chandos Street, W.1), at 7.30.—J. M. Offord: Fifty Years with the Quekett Microscopical Club.
WEST KENT SCIENTIFIC SOCIETY (at Wesleyan Hall, Blackheath), at 8.30.
ROYAL SOCIETY OF MEDICINE (Psychiatry Section), at 8.30.—Dr. M. Critchley: The Psychology of the Senile Psychoses.
PHARMACEUTICAL SOCIETY, at 8.30.—P. A. W. Self: Research (Harrison Memorial Lecture).
INSTITUTE OF BREWING (Scottish Section) (Annual General Meeting) (at Caledonian Hotel, Edinburgh).—A. C. Doull and S. E. Barnett: A Few Notes on some Physical Aspects of Fermentation and their Relationship to Brewing Practice.

WEDNESDAY, JANUARY 15.

ROYAL STATISTICAL SOCIETY (at Royal Society of Arts), at 5.15.
ROYAL SOCIETY OF MEDICINE (Surgery: Sub-Section of Proctology), at 5.30.—J. P. Lockhart-Mummery: Cinematographic Demonstration of The Operation of Perineal Excision of the Rectum, to be followed by a Clinico-Pathological Meeting.
INSTITUTION OF CIVIL ENGINEERS (Informal Meeting), at 6.—Prof. S. M. Dixon: Developments in Transportation by Cableways.
INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section), at 6.—H. A. Thomas: A Method of Measuring the Overall Performance of Radio Receivers.
INSTITUTION OF ELECTRICAL ENGINEERS (Sheffield Sub-Centre) (at Royal Victoria Hotel, Sheffield), at 7.30.—Lt.-Col. S. E. Monkhouse and L. C. Grant: The Heating of Buildings Electrically by means of Thermal Storage.
SOCIETY OF CHEMICAL INDUSTRY (Newcastle Section) (at Armstrong College, Newcastle-upon-Tyne), at 7.30.—R. D. Burn: Methods of Filtration in Industry.
BACUP TEXTILE SOCIETY (at Natural History Rooms, Bacup), at 7.30.—H. Mande: Plain Calico Weaving.
TEXTILE INSTITUTE (Yorkshire Section) (at White Swan Hotel, Halifax), at 7.30.—H. W. Martin: Humidification in Textile Works.
ROYAL METEOROLOGICAL SOCIETY (Annual General Meeting), at 7.30.—Sir Richard Gregory: Weather Cycles and Weather Recurrences (Presidential Address).—Presentation of Symons Medal to Dr. G. C. Simpson.
ROYAL SOCIETY OF ARTS, at 8.—J. Burton: Quality in Pottery.
ENTOMOLOGICAL SOCIETY OF LONDON (Annual Meeting), at 8.
FOLK-LORE SOCIETY (at University College), at 8.—Dr. W. R. Halliday: Some Notes on the Superstitious Man of Theophrastus.
ROYAL MICROSCOPICAL SOCIETY (Annual General Meeting), at 8.—J. E. Barnard: Resolution and Visibility in Medical Microscopy (Presidential Address).

HASLINGDEN DISTRICT TEXTILE SOCIETY (at Grammar School, Haslingden).—H. L. Trudgill: Slay Construction and the Care of a Fast Reed Slay.
SOCIETY OF DYERS AND COLOURISTS (Midlands Section) (at University College, Nottingham).—Dr. S. G. Barker: Measurement of Fading.
SOCIETY OF GLASS TECHNOLOGY (at Sunderland).

THURSDAY, JANUARY 16.

ROYAL SOCIETY, at 4.30.—J. R. Marrack and F. C. Smith: The Composition of Diphtheric Toxin—Anti-Toxin Floccules.—F. G. Spear: The Delayed Lethal Effect of Radium on Tissue Cultures *in vitro*.—J. T. Cunningham: The Vascular Filaments on the Pelvic Limbs of *Lepidosiren*, their Function and Evolutionary Significance.—*To be read in title only*.—Sir Frederick Keeble, M. G. Nelson, and R. Snow: The Integration of Plant Behaviour. I. Separate Geotropic Stimulations of Tip and Stump in Roots.—C. Todd: Cellular Individuality in the Higher Animals, with special reference to the Individuality of the Red Blood Corpuscle.—J. Ewles and J. B. Speakman: Examination of the Fine Structure of Wool by X-Ray Analysis.
LONDON MATHEMATICAL SOCIETY (at Royal Astronomical Society), at 5.—Prof. J. E. Littlewood: Mathematical Notes (12): On Functions Subharmonic in a Circle (III.).—R. E. A. C. Paley: On Some Problems connected with Weierstrass's Non-Differentiable Function.—S. Verblunsky: On the Limit of a Function at a Point. On the Denjoy Integral.—Dr. D. M. Wrinch: On an Integral Involving Legendre Functions and Related Integrals.
INSTITUTE OF METALS (Birmingham Local Section) (at Chamber of Commerce, Birmingham), at 7.—J. Fallon: Modern Annealing Furnaces.
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Kinematograph Group—Informal Meeting), at 7.
INSTITUTION OF ELECTRICAL ENGINEERS (Hampshire Sub-Centre) (at University College, Southampton), at 7.30.—Lt.-Col. S. E. Monkhouse and L. C. Grant: The Heating of Buildings Electrically by means of Thermal Storage.—T. G. N. Haldane: The Heat Pump—An Economical Method of Producing Low Grade Heat from Electricity.
INSTITUTE OF CHEMISTRY (Edinburgh and East of Scotland Section) (jointly with Society of Chemical Industry—Edinburgh and East of Scotland Section) (at 36 York Place, Edinburgh), at 7.30.—Short Papers.
BATLEY AND DISTRICT TEXTILE SOCIETY (at Batley Technical College), at 7.30.—Celanese: its Manufacture, Properties, and Uses (Lecture).
OPTICAL SOCIETY (at Imperial College of Science and Technology), at 7.30.—O. G. Hay: The Ross Modification of the Hilger Interferometers for Testing Large Optical Elements.—J. S. Preston: The Reflection Factor of Magnesium Oxide.—*Exhibits and Demonstrations*.—Raphael's Ltd.: Scientype Occluding Glass for Use in the Treatment of Squint. A Visual Test with a New System of Equi-photic Illumination.
CHEMICAL SOCIETY, at 8.—C. E. Coulthard, J. Marshall, and Prof. F. L. Pyman: The Variation of Phenol Coefficients in Homologous Series of Phenols.
ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, at 8.15.—Prof. Kuczynski: The Etiology of Yellow Fever with Special Reference to the Etiology of other Insect Borne Diseases.
BRITISH INSTITUTE OF RADIOLOGY, at 8.30.
ROYAL AERONAUTICAL SOCIETY (Yeovil Branch) (at Yeovil).—Wireless Apparatus for Aircraft.
SOCIETY OF CHEMICAL INDUSTRY (Glasgow Section) (jointly with Institution of the Rubber Industry) (at 39 Elmbank Crescent, Glasgow).—W. A. Williams: Electro-deposition of Rubber.
TODMORDEN TEXTILE SOCIETY (at Todmorden).—R. Holt: Defects in Yarn and how to avoid them.

FRIDAY, JANUARY 17.

ROYAL SOCIETY OF MEDICINE (Balneology Section), at 5.—Dr. V. Coates: Tissue Reaction in Rheumatic Disorders with Particular Reference to Subcutaneous Nodules.
BRITISH INSTITUTE OF RADIOLOGY, at 5.—Radiology in Bone and Joint Disease.
SOCIETY OF CHEMICAL INDUSTRY (Liverpool Section) (at Liverpool University), at 6.—Prof. E. C. C. Baly: The Activated Sludge Process for Sewage Disposal.
INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7.—T. Walley: The Pooling of Experience a Function of the Institution.
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group—Informal Meeting), at 7.—J. D. Johnston: Photographic Conventions.
JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7.30.—G. Andrew Marshall: London's Water Supply.
SOCIETY OF DYERS AND COLOURISTS (Manchester Section) (at Manchester).

SATURDAY, JANUARY 18.

NELSON TEXTILE SOCIETY (at Preston Technical School).—C. A. Harrington: Designing of Fancy Fabrics.
PHYSIOLOGICAL SOCIETY (at King's College).

PUBLIC LECTURES.

MONDAY, JANUARY 13.

EAST ANGLIAN INSTITUTE OF AGRICULTURE (Chelmsford), at 7.—W. S. Mansfield: Systems of Cropping to meet Modern Conditions.

TUESDAY, JANUARY 14.

GRESHAM COLLEGE, at 6.—A. R. Hinks: Universe Studies: The Massive Centre of the Galaxy. (Succeeding Lectures on Jan. 15, 16, and 17.)

WEDNESDAY, JANUARY 15.

ROYAL ANTHROPOLOGICAL INSTITUTE (at Portland Hall, Great Portland Street Extension of Regent Street Polytechnic), at 5.30.—M. C. Burkitt: Most Primitive Art.

THURSDAY, JANUARY 16.

KING'S COLLEGE, at 5.30.—Lieut.-Gen. H. B. Fawcus: The Royal Army Medical Corps.

SATURDAY, JANUARY 18, 1930

Science and History[1]

"WHAT is the use of historical knowledge ? " asked the late Frederic Harrison when beginning a lecture on the use of history, delivered in London some seventy years ago ' Is an acquaintance with the events, the men, the ideas of the past of any real use in these days ? " To such questions, he remarked that two very different answers might be given, one by the Gradgrinds who would say that it was of no use at all, and the other by the literary gossip who would say history had fifty uses With neither of these did Harrison agree, but running through his lecture was the thought that ' the proper study of mankind is man " No matter whether it be politics, religion, law, literature, science or art, whatever our system of education included, whilst man was wanting all the rest remained vague and incomplete, and aim less ' But the moment we learn the influence which some great discovery has had on the destinies of man the moment we note how all human thought was lighted up when Galileo said that the sun, and not the earth, was the centre of the world, the moment we feel that the demonstrations of Euclid are things in which all human minds must agree—indeed, are almost the only things in which all do agree—that moment the science has a meaning, and a clue and a plan "

It may perhaps be considered not a little surprising to find Harrison so long ago emphasising his view by a reference to science, for although, as Dr Singer recently reminded us, during the last few centuries no event has wrought so fundamental a change as the advent of the scientific way of thinking, there are yet professional historians who are content to tell the political history of the last three hundred years without reference to scientific discovery, scientific method, or the application of science to life and thought, showing a lamentable separation of humanistic from scientific studies This divorcement is no doubt partly due to the comparatively recent growth and spread of the scientific spirit and also to the highly technical character of scientific studies It may be, too, that teachers of science have made no greater attempt to connect science with the humanities than teachers of history to allow for the influences of science

However this may be, whether or no teachers should regard it a duty to connect scientific and historical studies, there can be no question that

[1] A History of Physics in its Elementary Branches including the Evolution of Physical Laboratories By Prof Florian Cajori Revised and enlarged edition, Pp xiii+424 (New York The Macmillan Co, 1929) 15s net

students of science should be familiar with the great pioneers as well as with their discoveries In the past there have been histories of mathematics, astronomy, electricity, and chemistry, and the names of Bossut, Montucla, Bailly, Priestley, Whewell, Grant, Clerke, and Thorpe recall some of the best known of historians of science, among whom Prof Florian Cajori of California holds a distinguished place His "History of Physics" has for long been familiar, and the new edition supplies the need of an up to date review of the subject First published in 1898, the book now runs to more than four hundred pages, and in these are surveyed the science of the ancients and the Renaissance and of the succeeding centuries In the review of the work of the twentieth century are sections devoted to radioactivity and the evolution of physical laboratories

"This is essentially an age", said Sir Ernest Rutherford recently, 'of pioneer activity based on the four great discoveries of X rays, radioactivity, the electron and the quantum theory", and it is just these things Prof Cajori deals with in the new section of his book

If the first steps towards the revival of scientific studies were taken in the fifteenth and sixteenth centuries, experimental science, thanks to the work of Gilbert, Galileo, Huygens, Newton, and others, made its first great onward stride in the seventeenth century It then passed through what has been called the materialistic age of the eighteenth century to the nineteenth, which brought with it law and order Last century Prof Cajori calls a century of correlation, the present is an age of fundamentalism

"The nineteenth century physicist was like the explorer who, reaching Niagara Falls, contemplated with intellectual satisfaction the grand display of natural phenomena before him The twentieth century physicist is like the explorer who, going further, arrived at Yellowstone Park and was perplexed by the endeavour to reconcile the fact that in that region not only does water *fall*, but also *rises* and shoots on high, not steadily but in intermittent streams"

All the hypotheses, all the mysteries of to day, however, we like to believe will eventually lead "to harmonious co ordination, to the old Pythagorean ideal of the 'harmony of the spheres'" The story Prof Cajori unfolds recalls some of the greatest achievements of the human intellect With profound speculation have been joined brilliant efforts of the imagination, patient study of facts, striking examples of manipulative dexterity, and a love of truth The unravelling of the secrets of Nature has been almost entirely the work of the peoples of western Europe, but the benefits are available for the whole world Modern communication and transport, the multiplication of industries and manufactures, the enlargement of the opportunities, and the amelioration of the lot of untold millions, what are they but the material gains due to the attempts to read some of the riddles of the universe? The greatest good derived from them, however, has been the emancipation of the spirit of man from credulity and superstition That is one of the lessons of history

Mathematical Notation

A History of Mathematical Notations By Prof Florian Cajori Vol 2 *Notations Mainly in Higher Mathematics* Pp xvii + 367 (London and Chicago The Open Court Co, 1929) 25*s* net

THE first volume of this invaluable work was noticed in our columns on July 6, 1929, p 4 The vast quantity of material which had to be digested constrained the author to divide it into two volumes, the first of which dealt with notations in elementary mathematics Had it been possible for one man to set forth the rest of the subject down to the present time on the same scale as the part of it included in the first volume, it would have required more volumes still The author has therefore limited himself to "the endeavor to present in the two volumes of this history a fairly complete list of the symbols of mathematics down to the beginning of the nineteenth century, and a fairly representative selection of the symbols occurring in recent literature in pure mathematics" As it is, Prof Cajori has accomplished a great work, for which mathematicians cannot be too grateful to him

The present volume is in four main sections 1 Topical survey of symbols in arithmetic and algebra (advanced part), 2 Symbols in modern analysis, 3 Symbols in geometry (advanced part), 4 The teachings of history The first section treats of letters representing magnitudes, the letters π and e, the evolution of the dollar sign, signs in the theory of numbers, signs for infinity and transfinite numbers, continued fractions and infinite series, signs in the theory of combinations, signs for determinants and logarithms, signs in theoretical arithmetic, and symbolism for imaginaries and vector analysis The second section deals with trigonometrical notations, symbols used in the differential and integral calculus, finite differences, the theory of functions, and finally in mathematical logic down to White

head and Russell. Section 3 covers the recent geometry of the triangle and circle, and projective and analytical geometry. Section 4 may be said to contain the moral of the story. It comprises quotations giving the individual judgments of eminent mathematicians, such as De Morgan, Maclaurin, Babbage, Mach, P. G. Tait, Glaisher, Whitehead, and H. F. Baker, on the interpretation of the history of the subject. Next come empirical generalisations by the author himself on the growth of mathematical notations, followed by suggestions for international co-operation as the only hope for the establishment of uniformity of notations.

When there is such a wealth of interest in the volume before us, it is difficult to make a selection of topics suitable for mention in a notice of this kind. One thing that stands out is the leading part played by Leibniz in the development of mathematical notations. Recognising the supreme importance of satisfactory symbols, Leibniz made a prolonged study of matters of notation, and, unlike others, for example, Oughtred and Hérigone, who launched 'off their own bat' a vast quantity of new signs, he first experimented with symbols for some thirty years, corresponded with mathematicians on the subject, and tried to ascertain their preferences, in order to secure, if possible, an agreed system. He was never better inspired than when he put forward his dx and dy in differential calculus and his sign $\int$ for integration. Yet he withheld the former from print for about ten years, and consulted in the meantime with Oldenburgh and Tschirnhausen. He discussed with Johann Bernoulli both the name and the principal symbol of the integral calculus. Leibniz himself favoured the name "calculus summatorius" and the symbol $\int$, Bernoulli the name "calculus integralis" and the capital letter I for the sign. The result was the happy compromise of adopting Bernoulli's name and Leibniz's symbol.

Nothing better attests the success of Leibniz's careful method of preliminary experimentation and consultation than the fact that no other mathematician has advanced so many symbols which have retained their place to the present day as did Leibniz. The tables which Prof. Cajori gives of the symbols used by Leibniz from time to time in his MSS. and printed papers occupy about nine pages. Leibniz's ideals for mathematical notation were part of his broader scheme of mathematical logic, which, however, was rather a programme than an actual accomplishment. He came to regard logic as "like a universal mathematics", and advocated a "universal language" or "calculus". "This true method", he said, "should furnish us with an Ariadne's thread, that is to say, with a certain sensible and palpable medium, which will guide the mind as do the lines drawn in geometry and the formulas for operations which are laid down for the learner in arithmetic." He prophesied the triumphant success of researches in this field in the famous sentence: 'I dare say that this is the last effort of the human mind, and, when this project shall have been carried out, all that men will have to do will be to be happy, since they will have an instrument that will serve to exalt the intellect not less than the telescope serves to perfect their vision."

Two interesting details may be added. The sign π for the ratio of the length of the circumference of a circle to that of its diameter was first used by William Jones in his "Synopsis palmariorum matheseos" (1706), without any advertisement, or any idea that he was doing anything noteworthy. William Oughtred had so early as 1647 used π/δ for the ratio, where π clearly stood for periphery ($\pi\varepsilon\rho\iota\varphi\acute{\varepsilon}\rho\varepsilon\iota\alpha$). Similarly, Jones, on p. 243, wrote "Periphery (π)", but twenty pages later he quotes an infinite series given to him by John Machin and adds simply "$= 3{\cdot}14159$, etc. $= \pi$."

The old sign for 'factorial n' (two lines forming a right angle), which was used by Todhunter and others in algebraical text-books, was due to the Rev. Thomas Jarrett (1805–1882), of St. Catherine's College, Cambridge, who must have been a remarkable man. Seventh Classic and thirty-fourth Wrangler in 1827, Jarrett made an extensive study of algebraic notation, which he discussed in an article of 1830 and much more fully (1831) in "An Essay on Algebraic Development containing the Principal Expansions in Common Algebra, in the Differential and Integral Calculus and in the Calculus of Finite Differences"; he was professor of Arabic in the University of Cambridge from 1831 until 1854 and Regius professor of Hebrew from 1854 until 1882, while in 1875 he edited the Sanskrit text of the Tale of Nala with vocabulary.

It is amusing to find De Morgan condemning the present sign for 'factorial n' in the "Penny Cyclopædia": "Among the worst of barbarisms is that of introducing symbols which are quite new in mathematical, but perfectly understood in common, language. Writers have borrowed from the Germans the abbreviation '$n!$' to signify $1 . 2 . 3 \ldots (n-1)n$, which gives their pages the appearance of expressing surprise that 2, 3, 4, etc., should be found in mathematical results."!

T. L. H.

Bacteriology in Medicine and Public Health

Medical Research Council A System of Bacteriology in relation to Medicine Vol 3 By W Bulloch, P Fildes, A T Glenny, H Henry, R T Hewlett, R A O'Brien, S G Paine, G F Petrie, Muriel Robertson, R St John Brooks, W G Savage, A C Thaysen, H G Thornton, R L Vollum Pp 413 (London H M Stationery Office, 1929) 21s net

THIS "System of Bacteriology" aims at giving a comprehensive survey of our present knowledge of bacteriology, specially in its relation to medical work The first volume of the series to be published gives promise of a very valuable contribution to scientific literature A book of this kind can only be undertaken by a series of authors, and the reviewer is placed in a rather difficult position He can have only a superficial knowledge of many of the articles, and his judgment of the whole work must, to a certain extent, be influenced by the quality of those papers with which he has an intimate knowledge Of the various papers, the three outstanding ones are those of Chaps viii, ix, and x In Chap viii there is a short history of plague by W Bulloch, but the main part of the chapter by G F Petrie is obviously written by a man of wide experience, and a real authority on the subject It deals with all aspects of plague infection—the characters of the bacillus, the problems in plague immunity, the transmission by the rat flea, the natural disease in rodents, and the various forms of plague in man with reference to its pathology, its diagnosis, and treatment It is a very valuable contribution and must be regarded as a standard work on the subject

Chap ix, on the organisms of gas gangrene, by Muriel Robertson, will commend itself to all who have worked on this subject Miss Robertson deals very fully with the characters of the bacteria and their classification, with their pathogenic action in man and in the lower animals, and with their toxins We may not agree with all Miss Robertson's conclusions, but she has done an extremely valuable piece of work, and has brought some order out of what has been practical chaos The part of this chapter on the preparation and testing of toxins and antitoxins, coming with the authority of R A O'Brien, is an addition of considerable value

It is appropriate that Chap x, on *B tetani*, should maintain the standard set by Miss Robertson Fildes, with Bulloch, O'Brien, and Glenny, have given to scientific bacteriologists and medical men in general a very worthy contribution on this important pathogen We commend these two chapters to all workers with the pathogenic anaerobes as the best summarised work which has yet been published on this subject

Of the merits of some of the other chapters we feel very incompetent to judge Chap i, on "The Economic Aspects of Bacteriology", is of considerable interest, and many points of practical importance have been brought out, but some of the descriptions are scrappy and give the impression that there has been very little advance in economic bacteriology One is surprised that no reference is made to the work of Winogradsky on 'retting', which we think is worthy of rather serious consideration On 'Baking' surely some reference should have been made to bacterial troubles other than 'Ropy bread' These are perhaps minor faults in a work which undoubtedly is both interesting and stimulating

Chap ii, "The Bacteriology of Water", is frankly disappointing The author deals with some factors which influence bacterial counts of water, such as storage, the effects of rain, food supply, temperature, etc, but surely the essential factor in determining the significance of counts is a knowledge of the local conditions of supply, the nature of the gathering ground, the situation of the storage areas, and number and efficiency of the filters A reservoir near the seaside may be frequented by gulls, and the *B coli* content there be greater than if the reservoir were in an inland area, but the *coli* contamination would be of little importance None of these points is even mentioned Then, we find no mention of the bacterial growth which occurs in pipes and tunnels, which is such a big economic problem to water engineers, or of the contamination so often found in leather and other washers

In the portion of this chapter dealing with sewage one is surprised to find no reference to the recent work of Wilson and others on the isolation of *B typhosus* and *B paratyphosus* What is given is well done, but the chapter suffers from the sins of omission rather than those of commission

Chap iii, "Bacteriological Aspects of the Dairy Industry", is well written and will be warmly welcomed by all those who are dealing with the bacteriological aspect of our milk supply The subject is not dealt with very fully, but the essential facts are given and are presented by a man who evidently has accurate knowledge of what is needed

Chap IV, "The Bacteriology of Foods", is interesting, but this subject very naturally raises the question of how much value is to be attached to the ordinary bacteriological examination of food stuffs, for example, the standard laid down for the bacteriology of shell fish is excellent, but the working bacteriologist has to deal with the material as collected from stores and shops where they are being sold many hours, or it may be days, after the removal from the beds So with other foods, there are so many factors that come in that each case has to be dealt with on its merits, and individual bacteriologists will disagree as to the importance to be attached to examination of eggs, fruit, vegetables, and even canned foods Public health authorities still lay considerable stress on this work, and Dr Savage has done the work well

Chaps V, VI, and VII have interested us very much They are well written, but as we have only touched the surface of these fields we do not feel competent to assess the value of the work From the authors of these chapters one would expect valuable contributions, and we have little doubt that to workers on these subjects these papers will be welcomed

Chap XI, on *Bacillus botulinus*, is written by Dr Hewlett, with sections by Dr Bulloch and Dr O'Brien Bulloch deals with the history and O'Brien with the large scale production of anti toxin, a subject on which no one is more qualified to speak The general characters of the bacillus, its fermentation reactions, its serology, and the variations in strains and types, are dealt with very fully The manifestations of botulism in animals, the disease in man, the effects of the toxin and the anti toxin, are all discussed Botulism has become more familiar in recent years, but we feel that this paper gives us a very complete and very accurate account not only of the disease, but also of the causal bacillus

Chap XII is simply a collection of material from various authors, with some observations by Dr Savage As we are told that the Salmonella group is to be dealt with in Vol 4, and as botulism has been dealt with in Chap XI, we think it would have been wiser either to have omitted this chapter altogether or to have treated the subject fully In its present condition it is not of great value

Taking the volume as a whole, we cordially congratulate the authors and the editors on the production The book will prove of enormous value to all bacteriological workers, and we hope that the other volumes will reach the same high standard

Gauges and Fine Measurements

Gauges and Fine Measurements By F H Rolt Edited by Sir R T Glazebrook Vol 1 *Standards of Length, Measuring Machines, Comparators* Pp xv + 366 Vol 2 *Limit Gauges, Measuring Instruments, General Methods of Measurement* Pp viii + 357 (London Macmillan and Co, Ltd, 1929) 42*s* net

IT is questionable if any section of engineering has hitherto suffered so much as the metrological from the want of a standard text book, and now, with the advent of this work, it is just as questionable if any section is better equipped with a really sound and comprehensive treatise The copious references at the end of each chapter show that much of a specialised nature has been written on metrology, but very few indeed of the many engaged on, or interested in, this branch of engineering have more than a fragmentary knowledge of the subject, and the number of persons who could deal with the whole field with the intimate knowledge of the expert is probably exceedingly small It is therefore fortunate that one of the few has produced this treatise

The history of the subject, as revealed more or less incidentally in the two volumes before us, shows that gauge construction and fine measurement was developing so continuously during the last twenty years that probably no particular time during that period would appear appropriate for writing a comprehensive book on the subject During the period 1840–80, Sir Joseph Whitworth introduced his famous system of end gauges, the first end measuring machine, and his system of producing truly flat surfaces by lapping a set of three plates The next important improvement was the introduction of the now common system of 'go' and 'not go' gauges With the exception of Michelson's classical experiment in 1892–93 on the determination of the length of the standard metre in wave lengths of monochromatic light, no further notable contribution to the art appears to have been made until the Johannsson (Swedish) Company introduced its block gauge and slip gauge system in 1908 This appears to have been the starting point of the great advances made since then These gauges opened a new field in the art of mechanical measurement, but, in the workshop, they were regarded as an expensive novelty and tardily adopted until, in 1917, a system of manufacturing gauges of this type was evolved in Great Britain, since when they have been produced in bulk for use in the tool room The degree of

accuracy attained in block gauges is exceedingly high, and the Johannsson gauges are supplied in four grades, respectively accurate to 2, 4, 8, and 12 parts in a million on the length of the gauge

The commencing point in the production of accurate length gauges is the legal standard of length, which is the distance between two parallel lines engraved on a metal bar Comparison between line standards is made with a pair of microscopes, under which the bars are placed in turn and the longitudinal position of the microscopes adjusted by a micrometer to bring them over the lines The adjustment necessary between the settings is a measure of the difference between the standards Yard or metre bars having well defined lines can be compared in this manner to an accuracy of one part in ten million, about 0 000,004 in

Comparing the absolute length of an end gauge with a line standard involves the problem of transference of size from lines to transverse faces A method of wringing on each end of the gauge a short auxiliary block, with a transverse line engraved on it, has enabled this to be effected to an absolute accuracy of one part in two million An end gauge of the standard yard or metre having been obtained, the gauges of shorter lengths are produced by a system of subdivision, making sets of gauges of equal length which together equal the standard In producing these sets a comparator is used which detects a difference of one millionth of an inch The accuracy of the finished gauges is checked by comparing various combinations giving nominally equal lengths, taking into account the thicknesses of the wringing films

The methods of measuring absolute length and making comparisons between end gauges by optical interference methods are exceedingly interesting, and the accuracy attainable is of the order of a fraction of a millionth of an inch The optical interference method is also adopted for testing the flatness of surfaces and for determining coefficients of expansion, but for measuring long gauges it is doubtful if it is more accurate than the mechanical method A further method which will give a natural control on standards of length in terms of time is being developed at the National Physical Laboratory

It is not to be gathered that attention is confined in Mr Rolt's work to these highly sensitive methods of measurement As an example, a system of sets of gauges is described for workshop, inspection, check and standard use, and, in the order given, each is ten times as accurate as the preceding set But these very accurate measurements of standards, etc, are the bedrock on which most of the many developments are based So much ground is covered that it is impracticable to refer in particular to the many instruments, machines, methods, etc, which are described, but it seems certain that nothing of value has escaped attention, and all are treated with the same thoroughness

In practical worth to those concerned in its subject, this work is a most valuable contribution to engineering literature It is very regrettable that circumstances have postponed the publication of the third volume dealing with screw threads, and its appearance will be looked forward to by all readers of the present two volumes

The Extinct Dwarf Elephants of Sicily and Malta

Les elephants nains des îles méditerraneennes et la question des isthmes pleistocènes Par Raymond Vaufrey (Archives de l'Institut de Paleontologie humaine, Memoire 6) Pp ii + 220 + 9 planches (Paris Masson et Cie, 1929) 160 francs

IT may seem strange to find a memoir on extinct dwarf elephants among the publications of the Institute of Human Palæontology These elephants, however, lived on several islands in the Mediterranean during part of the period when Palæolithic man ranged over both western Europe and northern Africa They were especially abundant in Sicily and Malta, where they are commonly supposed to have been stranded when a neck of land which connected Italy with Tunis became submerged, except in the fragments which those islands represent The proper understanding of them, therefore, has an important bearing on the geography of the Mediterranean region in Pleistocene times when early human migrations were taking place

Dr Raymond Vaufrey has studied the subject as thoroughly as possible, both by examining the collections of remains of dwarf elephants which have already been made, and by visiting the various caves and rock fissures in Sicily and Malta in which these fossils occur He himself has also made an important contribution to knowledge by providing new material to distinguish precisely the smallest form of dwarf elephant, commonly known as *Elephas falconeri*, from the somewhat larger form, *E melitensis* In the cave of Luparello, near Palermo, he found two superposed deposits, the upper containing only *E falconeri*, the

lower only *E melitensis*, so that there could be no confusion of the teeth and bones of the two forms He showed at the same time what had long been suspected, that the smaller form was of later date than the larger form

The technical descriptions of the teeth and bones are illustrated both by diagrammatic text figures and by several plates of most beautiful photographs The results are then summarised, and it seems clear that the dwarf elephants both of Malta and Sicily represent three distinct races of the well known European Pleistocene *Elephas antiquus*, as already recognised by Pohlig, with no relationship to the modern African elephant They must all have had a comparatively large head, for the size of the molar teeth is less reduced than that of the limb bones The largest members of the race *falconeri* would be less than a metre in height, those of the race *melitensis* would stand about 1 40 m high, and those of the race *mnaidriensis* about 1 90 m high As teeth of *E antiquus* of normal size have already been found in the oldest Pleistocene deposits of Sicily, and as the deposits in the caves are evidently of later date, the dwarfing must have occurred after the beginning of the Pleistocene period

To determine the exact date of the dwarfing of the elephants, Dr Vaufrey has made many important geological observations, and has searched especially for evidence of associated man He has not found any implements in the same deposits as the teeth and bones, and he is satisfied that the two human teeth discovered some years ago in the Har Dalam cave of Malta are neither Mousterian (as often claimed) nor from the elephant bearing layer He has found stone implements of very late Palæolithic type only in certain caves in Sicily well above the deposits containing remains of dwarf elephants He therefore concludes that Palæolithic man did not reach the Sicily Malta land area until after the elephants had become extinct They probably flourished in Mousterian times

In conclusion, Dr Vaufrey compares the Sicilian and Maltese fossils with the corresponding remains of dwarf elephants found by Miss Dorothea Bate in Cyprus and Crete, and by Dr Forsyth Major in Sardinia He considers that the remains from Cyprus belong to the races named *falconeri* and *melitensis*, while all those from Crete and Sardinia represent the race *melitensis* As Cyprus, Crete, and Sardinia can scarcely have been continuous with Sicily and Malta after the early part of the Pleistocene period, similar dwarf races must have arisen independently from *Elephas antiquus* in at least four areas

The dwarf elephants of the Mediterranean islands, therefore, must be regarded as the stranded descendants of a well known early Pleistocene European species which roamed over the Mediterranean lands before parts were broken up into islands As no distinctively African animals are represented by fossils in the same deposits as their remains, and as the dwarf elephants are not closely related to the modern African elephant, the Sicily Malta land area cannot ever have extended to Tunis During Pleistocene times, indeed, there was no land bridge in this region which man could traverse between the European and African continents A S W

Our Bookshelf

Surveying as Practised by Civil Engineers and Surveyors, including the Setting Out of Works for Construction and Surveys Abroad, with Examples taken from Actual Practice, intended as a Handbook for Field and Office Use, also as a Text Book for Students By John Whitelaw, Jun Eighth edition, thoroughly revised and enlarged by Col Sir Gordon Risley Hearn Pp xvi + 578 (London Crosby Lockwood and Son, 1929) 16s net

HAVING achieved in the past the distinction of appearing in seven editions, Whitelaw's "Surveying" has now, in the capable hands of Col Sir G R Hearn, been thoroughly revised and enlarged in accordance with the most recent developments in modern practice and issued in its eighth form Originally designed as a compact handbook, it has now become somewhat too bulky literally to fulfil such a function, but as a desk manual and a comprehensive text book for students it will command an even wider range of utility and service

In the new edition prominence is rightly given to developments in the field of tacheometry or stadia surveying, and to other means of rapid measurement required in modern prospective work and for kindred purposes, in which the plane table and aneroid barometer also find a field of usefulness Photographic and aerial surveying similarly receive notice Attention, moreover, is directed to modern instruments of precision, and a description is given of the micrometer microscope

To those who are not familiar with the scope of the work, especially in its enlarged form, the following summary of the contents of the successive chapters may be useful surveying by means of the chain only, surveying with the aid of angular instruments, levelling operations, adjustment of instruments, railway and road surveys, tacheometric surveying, tunnel work, water supply surveys, hydrographical surveying, astronomical observations connected with surveying, surveys abroad in jungle, desert, and

unmapped open country, and trigonometrical or geodetic surveys An appendix adds a number of useful details on various points, including plan preparation and photographic reproduction There is a serviceable index B C

Bahnbestimmung der Planeten und Kometen Von Prof Dr G Stracke Pp viii + 365 (Berlin Julius Springer, 1929) 26 gold marks

THIS is a volume of convenient size, and gives in a compact form all the details of orbit computation Dr Stracke has great experience in such computations from his extensive work on minor planet orbits for the Berlin Rechen Institut The first chapter gives a description of undisturbed motion about the sun, and the relation of the geocentric to the heliocentric places The next gives the various reductions that the observed positions need before commencing the orbit computation The third chapter is the fundamental one, it describes three different methods of deducing an elliptical orbit from three observations, and two of doing so from four observations, then follow two methods for a circular orbit, and two for a parabolic one, it is to be regretted that Leuschner's method is not included, as many computers prefer it to any other, and it is very effectively employed in America The next chapter explains the calculation of ephemerides, including all the refinements necessary when exact ones are required

The chapter on perturbations describes the methods of Cowell and Numerow, in which the co ordinates x, y, z are determined by mechanical quadratures, also that of Encke, in which the perturbations of x, y, z are thus calculated Lastly, there is a chapter on the improvement of orbits by the inclusion of later observations

There are numerous examples, the elliptical orbit of planet No 996 is worked out from an arc of 50 days, and a parabolic orbit is found for Orkisz's comet from an arc of a month There is a collection of tables at the end of the volume and also an extensive list of books and pamphlets relating to the subject The very useful X, Y tables of Innes, published since the list was prepared, should be added to it A C D C

Ur of the Chaldees a Record of Seven Years of Excavation By C Leonard Woolley Pp 210 + 16 plates (London Ernest Benn, Ltd, 1929) 7*s* 6*d* net

MR WOOLLEY'S brief but compendious account of the excavations at Ur during the seven seasons in which he has been in charge of the joint expedition of the British Museum and the Museum of the University of Pennsylvania, is both timely and convenient Periodical reports and newspaper articles freely contributed to the Press by Mr Woolley have kept his public informed of the progress of the work in each season, but everyone will be glad to have at hand this convenient summary of the results as a whole

Reading through Mr Woolley's narrative in this connected form, and surveying his material as it is possible to do here, only serves to bring home with telling force the importance of this work for the history of civilisation During the past two seasons, apart from the evidence for a flood of unexpected dimensions, of which the interest will vary according as it is taken to bear upon Biblical narrative, the excavation of the Royal and 'private' tombs, with their rich treasure and elaborate offerings of human and animal victims, has thrown an entirely new light upon ritual and culture in Sumeria at this early stage It has given us a new view of the artistic achievements of the early Sumerians for which even the discoveries of previous seasons at El Ubaid and Ur itself had not prepared us By the side of these achievements, the excavation of the great temple at Ur seems to pale in interest, but Mr Woolley's account of this remarkable piece of work will serve to restore something of a sense of proportion

Physical Chemistry By Dr J B Firth Pp iv + 292 (London University Tutorial Press, Ltd, 1929) 5*s* 6*d*

DR FIRTH has undertaken a difficult task in attempting to outline the modern doctrines of physical chemistry in a book of less than 300 pages This task has been rendered more difficult by the inclusion of an introductory chapter on the atomic and molecular theories and a final chapter on atomic structure The author has therefore summarised the subject matter of the usual elementary course of physical chemistry within the narrow limits of about 240 pages, but has done his work so well that no important omissions appear to have been made Of up to date topics the use of the parachor is briefly but adequately described, but the modern theory of complete ionisation of strong electrolytes is only referred to in a footnote which states that "the assumption that the speed of the ions remains unaltered on dilution holds for weak electrolytes but not for strong electrolytes" The text includes some 50 figures and a collection of 106 problems and test questions

The Rise of Modern Physics a Popular Sketch By Prof Henry Crew Pp xv + 356 + 24 plates (London Baillière, Tindall and Cox, 1928)

FOR many years Prof Crew has been lecturing to students of Northwestern University (in Evanston, a suburb of Chicago) on the history of science He has now put his lecture notes into book form, so that they may benefit a wider circle His book is not intended to be a serious critical study of the history of physics, but rather an outline that will enable the modern student to appreciate the labours of the pioneers of the science This object it achieves admirably It may occasion surprise to find that Galileo receives much more attention than does Newton, but this is probably due to the fact that the author had previously made and published an intensive study of the life of Galileo

The book is lucidly written and may be perused with profit by all students of physics, and indeed by all whose interest is in the domain of science L J C

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications]*

Loss of Ultra-Violet Transparency in Glasses

IN a recent issue of NATURE (Sept 21, 1929, p 441) Messrs Wood and Leathwood described some experimental work on the ageing or solarisation of ultra violet transparent glasses, from the results of which they arrived at two conclusions (1) that complete degeneration by a mercury arc lamp results in a greater loss of ultra violet transparency than does natural solarisation, and (2) that natural solarisation of U V glasses is complete after only a few days' exposure to the sun

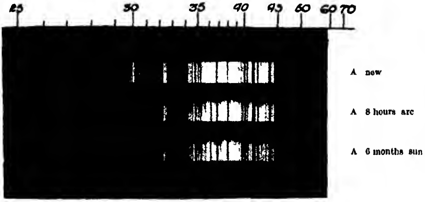

FIG 1 —Natural and artificial ageing of glass 'A';

The first of these conclusions is a confirmation of observations published by me in a paper in *Glass* (September 1928) in which it was shown that only eight hours' treatment with a mercury arc lamp was sufficient to reduce the ultra violet transparency of four different types of glass to the same extent as six months' exposure to the sun and a practically complete hemisphere of sky Throughout the whole of the comparisons of natural and artificial ageing described in that paper, a standard period of eight hours' arc treatment was adopted, although prior to that date all the test reports given by the National Physical Laboratory and by the Reichsanstalt of which I was cognisant, showed that artificial ageing had been carried out by mercury arc lamps for periods of twenty four hours The similarity of the effect of six months' natural solarisation and eight hours' artificial ageing on one particular glass (glass 'A') is clearly shown in Fig 1

Among the data given by Wood and Leathwood an interesting fact is given but not emphasised, namely, that all glasses are not equally susceptible to this loss of ultra violet transparency This can best be brought out by photographs taken, developed, and printed under identical conditions, rather than by quoting figures Pieces of two glasses ('A' and 'H') of similar thickness but different manufacture were cut into three sections One section of each was preserved in the 'new' condition, the other two were simultaneously subjected respectively to five hours' and ten hours' artificial ageing, six inches below a quartz mercury lamp Afterwards, photospectrographs of the transmission of each of the six sections were taken on one plate, using an iron arc and giving a uniform twenty seconds' exposure in each case

The results, reproduced in Fig 2, clearly show that even this severe treatment barely affects the glass 'H', but, on the other hand, the glass 'A' suffers a serious reduction in ultra violet transparency when judged either by the extent of the transmission or by the brightness in the important zone between 2950 A and 3200 A These observations have recently been confirmed by National Physical Laboratory tests on a sample of the glass 'H' (independently selected by a well known London architect) and on a piece of the glass 'A' bought in the ordinary way of business These tests show that at 3050 A the glass 'H' has an initial transparency of 68 per cent, falling to 53 per cent on arc ageing, while the glass 'A' has an initial transparency of 64 per cent, falling to 45 per cent on arc ageing Natural solarisation shows up the difference between these two glasses even more clearly

Turning now to the second conclusion arrived at by Wood and Leathwood, namely, that natural solarisation is complete in comparatively few days

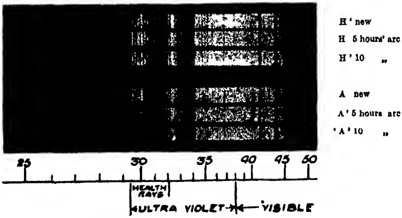

FIG 2 —Comparative artificial ageing of glasses 'H and 'A

This is contrary to my experience and to that of independent investigators who have made a detailed study of the subject, as shown by the following data At the beginning of last January I took pieces of five types of ultra violet glass, each cut into a number of sections One section of each was preserved in its new condition, the others were exposed in a horizontal roof for periods of 1, 2, 3, 6, and 10 months, after which period, photographs of their transmissions were taken Since a glass 'S' shows this solarisation effect better than most of the others and much more pronouncedly than the glass 'H', its transmission photograph is reproduced to illustrate

the results (Fig 3) This photograph clearly shows that, though the first month's exposure is most effective, the loss of transparency proceeds to a marked extent during the second and third months, and at a slower rate even up to six months There appears to be no appreciable change after the lapse of six months—as shown by the transmission of the samples exposed for six and ten months In considering these results it must be remembered that the first three months of exposure were comparatively sunless winter months, while the later months were particularly bright and sunny

Coblentz and Stair, in a recent paper from the Bureau of Standards, show that a sample of an ultra violet glass, exposed at Washington from October

10 ,

FIG 3 —Natural solarisation of glass S'

1927 to June 1928, suffered a reduction of transparency from an initial value of 55 per cent at 3020 A to 48 per cent after one month, to 47 per cent after three months, to 45 per cent after six months, and to 43 per cent after nine months They express the opinion that this photochemical change may require several years' exposure to the sun before a state of perfect stabilisation is reached Whether this is a too pessimistic view or not, the photograph reproduced in Fig 3 and the general results obtained by Coblentz and Stair show conclusively that, though the greatest loss of transparency occurs during the first few weeks of exposure to the sun, this deterioration is not generally complete until after the lapse of six months

Optical Superposition among Menthylamines and Menthols

THE following relative molecular configurations have recently been advanced for the four possible series of stereoisomeric menthylamines, all of which are now known (*Jour Chem Soc*, p 2170, 1927)

Me | H	Me | H	Me | H	Me | H	(1)
H | NH_2	NH_2 | H	NH_2 | H	H | NH_2	(3)
H | Prβ	H | Prβ	Prβ | H	Prβ | H	(4)
l Menthylamine	*d neo*	*d-iso-*	*d-neoiso*	

The respective values of $[\alpha]_D$ (in chloroform) for the acetyl derivatives are − 81 7°, + 53 0°, + 30 7°, and − 2 6° The sum of any two of these values is approximately equal in magnitude and opposite in sign to the sum of the other two, and from a series of observations which we have just concluded upon 14 other derivatives of each base we find that this curious relationship holds generally for menthylamine derivatives of the type R CH_2 CO NH R', and for the free bases, it obtains, moreover, for $[\alpha]_{5461}$, as well as for $[\alpha]_D$ When R is phenyl and the adjacent methylene group is simultaneously eliminated, the relationship fails, nor is it evident in derivatives of the type R CH NR'

Upon selecting a suitable derivative, for example, the acetyl derivative, and superposing the four configurations shown above, it is found that the algebraic sum of the four values of $[\alpha]_D$ approximates to zero In the process of superposition, the optical effects of the asymmetric groups (3) and (4) would appear to undergo a mutual neutralisation, owing to the opposed spatial dispositions of these groups in the various molecules The possibility of such an annulment is not immediately obvious, however, for the asymmetric group (1), which has the same spatial disposition (that is, Me | H) in all four configurations Unless the approach to a zero value is purely fortuitous, which appears improbable, a simple explanation may be sought in the assumption that the asymmetric group (1) exerts a numerically constant rotational effect in all four configurations, the positive or negative sense of which is determined by the nature of the attached complex group (*vide infra*) If, in two of the four instances, the effect is negative, and in the other two positive, the origin of the zero value is explained

By taking the mean optical rotation of the *l* and *d iso* acetyl derivatives, the rotational effect of the asymmetric group (1) is evaluated at 25 5 units, and the mean optical rotation of the *d neo* and *d neoiso* acetyl derivatives gives the almost identical result 25 2 units the average value is thus 25 4 units Similarly, the average value for the combined rotational effect of the remaining asymmetric centres, (3) and (4), is 56 2 units for *cis* H and 27 8 units for *trans* H

Proceeding now to a generalisation, it seems that in each of the eight stereoisomeric acetylmenthyl amines the asymmetric group (1) has a constant value of 25 4 units of specific rotational power (in chloroform solution, for sodium light) When the configuration Me | H is attached to $\begin{array}{c|c} H & NHAc \\ H & Pr\beta \end{array}$ or to $\begin{array}{c|c} NHAc & H \\ Pr\beta & H \end{array}$ it exerts a lævo rotatory effect, but when the same configuration is attached to $\begin{array}{c|c} H & NHAc \\ Pr\beta & H \end{array}$ or to $\begin{array}{c|c} NHAc & H \\ H & Pr\beta \end{array}$ its effect, although equal in magnitude, is dextro rotatory Further, the complex asymmetric groups $\begin{array}{c|c} H & NHAc \\ H & Pr\beta \end{array}$ and $\begin{array}{c|c} H & NHAc \\ Pr\beta & H \end{array}$ have respective constant values of − 56 2 and − 27 8 units of specific rotational power From the three constants, 25 4, 56 2, and 27 8, it is possible to calculate the value of $[\alpha]_D$ for any acetyl menthylamine the relative molecular configuration of which is known A similar statement applies to any menthylamine derivative of the type R CH_2 CO NHR' which we have examined up to the present As an illustrative example, the configuration of acetyl *d* menthylamine may be selected $\begin{array}{c|c} H & Me \\ NHAc & H \\ Pr\beta & H \end{array}$ The complex configurational unit $\begin{array}{c|c} NHAc & H \\ Pr\beta & H \end{array}$ has the value + 56 2, Me | H attached to it has the value − 25 4, so that obviously the value for H | Me is + 25 4 Thus, $[\alpha]_D$ for acetyl *d* menthylamine is 56 2 + 25 4 = + 81 6

It appears, then, that the magnitude of the optical

effect of the asymmetric group (1) is retained throughout the various stereoisomeric forms, independently of the other two asymmetric groups which are present. No corresponding constancy can be postulated, however, for either of the asymmetric groups (3) or (4), taken separately. A marked discrepancy is noticed when the rotational effect of either of them is calculated in two ways. Thus, the optical effects of the asymmetric groups (3) and (4) appear to undergo striking fluctuations, determined by their immediate environment in the molecule. The apparent constancy of the optical effect of the asymmetric group (1) may perhaps be correlated with the fact that there is no alteration in its immediate environment when it is rotated through an angle of 180°.

It will be of particular interest to conduct similar investigations with the menthols and their derivatives, when the complete series eventually becomes accessible. Meanwhile, a close parallelism is discernible between the optical rotations of the menthylamines and the corresponding menthols, so far as the latter are known. The following comparison of values of $[\alpha]_D$ is instructive:

	l	*d neo*	*d iso*	*d neoiso*
Menthylamine (no solvent)	−43·2	+15·1°	+28·8	+0·3°
Menthol (no solvent)	−49·9	+19·6	—	—
Menthol (in alcohol)	−49·1	—	+27·0	?

Unfortunately, the specific rotatory powers of the *neo*menthols appear not to have been observed in alcohol; but from the data available for *l* menthol (Gildemeister, "Die Ätherischen Öle", Leipzig, I 469, 1928), the value may be accepted provisionally as being practically identical with that of the liquid substance. Applying, then, to the specific rotatory powers of the three known series of menthols processes similar to those developed above for the analogous menthylamines, the appended specific rotational values are calculable for the three fundamental asymmetric groups:

SPECIFIC ROTATIONAL VALUES FOR ASYMMETRIC GROUPS IN THE MENTHOLS—$[\alpha]_D$ IN ALCOHOL

Me | H	H | OH / H | Prβ	H | OH / Prβ | H
+11·1	−38·0	−8·5

CORRESPONDING VALUES FOR THE MENTHYLAMINES—NO SOLVENT

+7·5	−36·0	−7·4

The prediction may now be made that the value of $[\alpha]_D$ for the unknown *d neoiso*menthol, having a configuration similar to that of *d neoiso*menthylamine above (*Chemistry and Industry*, p. 878, 1927), will be −8·5 + 11·1 = +2·6°.

It is possible in this place to give only a brief outline of the relationships concerned, and details will be published elsewhere. Further studies of this kind may be expected to throw a good deal of new light upon the so-called principle of optical superposition. The main obstacle to such work lies in the great difficulty of gaining access to complete stereoisomeric series of suitable substances.

Structural Variation in the Chromosomes of *Campanula persicifolia*.

CHROMOSOME behaviour at meiosis has been described in *Campanula persicifolia* to show the relationships of diploid, triploid, and tetraploid forms.[1] The haploid number is eight. In the diploid, as a rule the chromosomes are associated at both ends forming rings, but occasionally association at one end gives a rod. In the tetraploid, the majority of the chromosomes still associate in pairs, but this is varied by the formation of rings and chains of four as well as by failure of pairing. In the triploid the third chromosome is occasionally associated with its homologues in a chain, but more usually free. The end to end association always found at metaphase follows terminalisation of from two to five interstitial chiasmata found at a diplotene stage characteristic of parasynapsis. This terminalisation accounts for the failure of quadrivalents by the cancellation of chiasmata.[2] We may therefore speak of the chromosomes as being joined at metaphase by terminal chiasmata with an approximate average of two to each chromosome.

FIG. 1.

In plants from two sources anomalous chromosome behaviour has been found at meiosis: (i) a white double variety in cultivation; (ii) a type form found wild at Gmunden, Austria (two seedlings). These have, instead of eight rings of two at metaphase, six rings of two and one group of four which takes the forms shown in Figs. 1 and 2.

The types are given in order of frequency. The last three, in which one of the four chiasmata necessary for

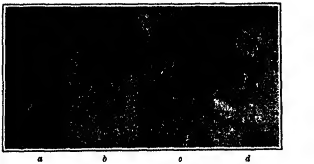

FIG. 2.—Microphotographs of metaphase × ca. 1500. *a*, normal type; *b*–*d*, structural hybrid type. *a*, 8 bivalents; *b*, type I ring; *c*, type III ring; *d*, type IV chain.

a ring may be said to have failed, are in small proportion in the white double and have not been found in the Austrian seedlings. The failure of two or three chiasmata, giving two pairs or actually unpaired chromosomes instead of the ring of four, has been observed occasionally in both forms.

Specific properties of ring formation are inherited. Twenty nine plants were raised from the cross white double by the seedling from Murols (Puy de Dôme). Of four that were examined, three had the ring of four as in the female parent, one had simple pairing (8 bivalents).

The somatic complement has been examined in several stocks (Fig. 3). Some (for example, Murols and Varna) have all chromosomes medianly con-

[1] Gairdner, *Jour. Genet.*, 16, 1926.
[2] Darlington, *Jour. Genet.*, 21, iii, 1929.

stricted, others (for example, Gmunden) have five of the eight pairs with subterminal constrictions. Other more complex structural changes are still under investigation.

It has been suggested that the parasynapsis (side-by-side conjugation) of homologous parts of chromosomes is a universal condition of meiosis [3] and that therefore the association of more than two chromosomes in a diploid must always be due to the interchange of segments between non-homologous chromosomes in the complement of one parent (an explanation already proposed in the case of *Datura* [4]). Such diploid zygotes must be ***structural hybrids***, for they are produced by the union of gametes dissimilar in respect of the structure of their chromosomes. The behaviour of these anomalous forms is in agreement with this hypothesis in the following respects:

(1) The occurrence of interstitial chiasmata at prophase shows that pairing of the chromosomes in *Campanula* is by parasynapsis. The end-to-end pairing is a secondary condition of known origin.

(2) The ring of chromosomes (here, as in *Pisum* [5]) may be represented as consisting of four segments A, B, C, and D occurring as chromosomes AB and CD in the complement derived from one parent, BC and DA in the complement derived from the other. Then, since each of the segments has the specific property of pairing with an identical segment, the only configuration possible will be (i) the ring, and (ii) chains derived from the ring by failure of one or more chiasmata in the ring. Configurations of the X and Y shapes found in tetraploids and depending on the formation of multiple chiasmata between the ends of several segments do not occur.

Murols Gmunden

FIG 3.—×2000

(3) The orientation of the ring when formed is in no way different from that found in *Œnothera* or *Rhœo* [2]. That is to say, apart from the usual segregation of pairing chromosomes to opposite poles, non-disjunction may occur (type III). These variations occur equally in tetraploid *Tradescantia* [3] and *Primula sinensis* (unpublished).

(4) As in the tetraploid form,[1] so with four associated chromosomes in the diploid, failure of pairing sometimes occurs. The regularity of pairing should depend on the length of the segment of chromosome exchanged.[3]

(5) The ring of four in the diploid is more constant than in the tetraploid, because in the absence of competition there can be no cancellation of chiasmata.

(6) As in *Œnothera*, *Rhœo*, and *Datura*, the specific pairing properties of the chromosomes are inherited unchanged.

(7) Different races of *C. persicifolia* have visible structural differences in their chromosomes. Structural variation is a necessary antecedent of structural hybridity, but has not previously been demonstrable in the somatic chromosomes except in a tetraploid, *Tradescantia virginiana*.[2]

On these grounds we conclude that the present observations show in *Campanula persicifolia* the incipient stages of structural hybridity. They provide another valuable link connecting the complex permanent structural hybrids in *Œnothera* and *Rhœo* with everyday homozygous organisms, and thus enable us to regard all types of diploid ring formation as due to a modification of the results of ordinary parasynapsis produced by this condition of structural hybridity.

Optical Anisotropy and Theoretical Intensities of Raman Lines in Diatomic Gases

WE wish to consider the scattering bound with the vibrational transitions $|\Delta v| = 1, 2$ (Raman lines) and $\Delta v = 0$ (Rayleigh lines). In each case there is a well known [1] selection rule for the rotational transitions $\Delta j = 0, \pm 2$. The plus sign gives rise to a double R branch, the minus sign to a double P branch, and $\Delta j = 0$ to a Q branch. Initial and final states correspond to an electronic ground level $^1\Sigma$.

In the case $\Delta v = 0$, a discussion of the Kramers-Heisenberg dispersion formula leads to the following values for the scattering moment; $M(\pi)$ and $M(\sigma)$ are respectively the components parallel and perpendicular to the electric field E of the plane polarised monochromatic incident light wave. R and P branch, $\Delta v = 0, j \longrightarrow j \pm 2$:

$$M^2(\pi) = E^2\gamma^2\ 2/15\ J(j \pm 1) \quad M^2(\sigma) = E^2\gamma^2\ 1/10\ J(j \pm 1)$$

Q branch, $\Delta v = 0, j \longrightarrow j$:

$$M^2(\pi) = E^2\zeta^2(2j + 1) + E^2\gamma^2 I(j) \quad M^2(\sigma) = E^2\gamma^2\ 1/15\ J(j)$$

where $J(j) = j(j+1)/(2j+1)$. $I(j)$ is a rational function of j which reduces to $2j/45$ for large values of j. ζ and γ are defined as

$$\zeta = (\alpha + 2\beta)/3 \qquad \gamma = \alpha - \beta$$

where, as seen below, the constants α and β represent the influence of the electronic levels only on the intensity of the scattered lines. The relations are sums taken over the $(2j + 1)$ degenerate rotational states.

In the case $v - 1 \rightleftarrows v$, similar expressions are obtained, with the difference, however, that α and β are replaced by $\kappa\alpha'\sqrt{v/2}$ and $\kappa\beta'\sqrt{v/2}$, where $\kappa^2 = \nu_{rot}/\nu_{osc}$ (κ^2 = 1/10 to 1/50; $\nu_{rot} = h/4\pi^2 I$, I moment of inertia; ν_{osc} = frequency of oscillation in the ground level). If $|\Delta v| = n$, the scattering moment is proportional to κ^n and to $\alpha^{(n)}$ or $\beta^{(n)}$.

Denoting by $\alpha(R)$ the electronic polarisability of the molecule along its axis of symmetry, the nuclei being a fixed distance R apart, the following connexion is found for the α's:

$$\alpha(R) = \alpha + \alpha'(R - R_0)/R_0 + \ldots \alpha^{(n)}[(R - R_0)/R_0]^n$$

where R_0 is the nuclear distance in the position of equilibrium of the ground level. Similarly, $\beta(R)$ means the polarisability along any direction perpendicular to the axis. Only matrix elements of electronic transitions from the ground level Σ to any Σ level enter into the expression for α, and to any Π level for β. Both α and β vary slowly with the incident frequency, except in the neighbourhood of an electronic frequency of absorption.

An apparently good check on the formulæ was obtained on comparing with the photographs for gaseous hydrogen made by Rasetti.[2] The formulæ still show that the depolarisation of any line in the

[1] E. C. Kemble and E. Hill, *Proc. N. A. S.*, 15, 387, 1929. F. Rasetti, *ibid.*, 15, 515, 1929.
[2] F. Rasetti, *Phys. Rev.*, 34, 367, 1929.

P- or *R* branch, that is, the ratio of its σ to π components, observed in a direction perpendicular to *E*, *should be the same and equal to 3/4* for *all diatomic molecules*, irrespective of the incident frequency and the temperature

The total intensity of each *unresolved* branch can be calculated For temperatures not too much below the room temperature, the intensity of the *Q* branch remains nearly constant, whereas there is a *dissymmetry* in the intensities of the *P*- and *R* branches, the *R* branch, on the low frequency side, being the stronger the more the temperature is decreased Thus, the total unresolved *P Q R* line should be *diffuse*, with a slight apparent shift of the centre of gravity of the line towards the red This dissymmetry should usually be more pronounced for the σ- than for the π component The effect, which seems to exist in vapours,[3] is, however, insufficient to account for the large frequency shift of the scattered lines towards the red, observed in such liquids as ammonia and hydrogen chloride[4]

Finally, the intensities in the *P* and *R*-branches are proportional to the factor of *optical anisotropy* $\gamma^2 = (\alpha - \beta)^2$, for the intensities vanish when $\alpha = \beta$, that is, when the electronic polarisation is the same in every direction A connexion between diffuseness of the lines and optical anisotropy has been noticed experimentally by Raman[5] A slight dependence on the incident frequency is also to be expected for the anisotropy

The relative scattering intensities of a Rayleigh and the related Raman lines corresponding to transitions from the same vibration level are in the ratios ϵ^2 $(\epsilon')^2\kappa^2$ $(\epsilon'')^2\kappa^4$ where $\epsilon^{(n)}$ means a quantity of the order of magnitude of $\alpha^{(n)}$ and $\beta^{(n)}$ As has been emphasised elsewhere,[6] the presence of the factor κ^2 explains why harmonic Raman lines, when they can be detected, are so faint One must, however, take into consideration the additional influence of the electronic levels, as marked by the ϵ's, which may modify somewhat the expected intensity ratios Moreover, the dependence on the frequency may also not be the same for the different ϵ's, although the trend of variation remains Thus it can be explained why it is that the ratio of intensities of the Raman and Rayleigh lines has not been found to be rigorously independent of the incident frequency[6]

Although the theory has been developed for diatomic molecules, it seems that some of the preceding conclusions can be extended to polyatomic molecules The only assumption made in deducing the above results is that the molecule is stable in the ground state The rapidity of convergence of the expansion for $\alpha(R)$ is immaterial

Intermetallic Compounds in Mercury

ATTENTION has not previously been directed to the possibility of formation of intermetallic compounds (other than with mercury) in liquid mercury It is expected *a priori* that if such compounds are formed they would be unstable With Mr P V F Cazalet I am investigating this problem and our preliminary results are given below

Pairs of metals more reactive than mercury have been obtained in mercury either by direct solution or by electrolysis These mixed amalgams have been subjected to the action of potassium permanganate or other oxidising agents in sulphuric acid solution and the resultant solution of sulphates quantitatively analysed So far, in none of the reactions investigated does mercury itself take part The reactions occurring may be classed under three heads, namely

(1) The more reactive metal is completely removed from the amalgam before the second takes part in the reaction This occurs with cadmium and copper, cadmium and iron, lead and copper, lead and iron, the first named in each case acting as the more reactive metal

(2) The more reactive metal alone takes part in the reaction, then, before it is removed, the second metal begins to take a part which increases until both metals are completely removed from the mercury, at which stage the first is scarcely detectable This occurs with tin and iron

(3) The more reactive metal alone takes part in the reaction until its concentration (in atoms), relative to that of the second metal in the amalgam, is represented by a simple ratio Then, and until both metals are completely removed by the oxidising agent from the amalgam, does the atomic ratio of the metals taking part in the reaction remain simple and constant This occurs with tin and copper, zinc and copper, zinc and iron, copper and iron

These 'constant reducing' mixtures of metals behave in each case like an amalgam containing the less reactive metal, and certainly markedly different from an amalgam of the more reactive metal as regards solubility in mercury, action on acids, and action on certain oxidising agents For example, whereas zinc is soluble in mercury to the extent of about 1 per cent, the zinc copper complex is totally insoluble, whereas zinc in mercury reduces quinquevalent vanadium to the divalent state without difficulty, the zinc copper complex reduces it only to the quadrivalent state Again, whereas tin in mercury (as in the free state), when oxidised by ferric sulphate, pauses in the stannous condition before being oxidised gradually to the stannic condition, the tin copper complex may be shown to be oxidised directly to the stannic condition

The complexes examined tend on standing to dissociate into the more reactive metal, and either the less reactive metal or a similar complex richer in the less reactive metal Vigorous shaking prevents the dissociation or restores the association The empirical formulæ of the complexes so far obtained are $SnCu_2$, $SnCu_3$, $SnCu_4$, $ZnCu$, $ZnFe$, $ZnFe_6$, and $CuFe$ The second and fourth of these are known to metallurgists, and the third may possibly be the known compound Sn_8Cu_{31} Whether these complexes are true compounds, however, must depend upon how accurately their analysis gives a simple ratio of atoms and upon their examination after removal from suspension in mercury

Some Bands of the Carbon Molecule

IN a recent communication (NATURE, Jan 11), Dieke and Holtgreven have given details of a new system of the C_2 molecule The band heads (degraded to the ultra violet) have long been known from the work of Deslandres and D'Azambuja (*vide* Kayser's "Handbuch", vol 5, p 234), while in 1916, Raffety (*Phil Mag*, vol 32, p 546) recorded four of the strongest bands as associated with the Swan bands under his experimental conditions Vibrational and fine structure analysis have now been made for the first time by

Dieke and Holtgreven, making this the third known system of the C_2 molecule

I had also recently made a vibrational analysis and a partial rotational analysis of this system, and my conclusions are in substantial agreement with these workers Although there is no state in common with the three known ($^3\Pi$) states of this molecule, there is ample evidence both from experimental conditions and fine structure analysis that the emitter is C_2 The characteristic 'staggering' of the structure lines due to σ type doubling, combined with alternate missing levels due to symmetry of the molecule is very evident, and the transition $^1\Pi \rightarrow {}^1\Pi$ is without doubt correct I have obtained plates of these bands in the first order of a 21 ft grating, and wave lengths of the heads are given in the accompanying table

Int	Wave Length (Heads)	ν (in Vacuo)	n	n''
5	3398 12	29419 6	3	1
5	3399 73	29405 7	2	0
7	3587 65	27865 5	3	2
7	3592 9	27824 8	2	1
8	3607 3	27713 7	1	0
5	3825 65	26132 0	1	1
10	3852 2	25951 9	0	0
1	4026 92	24825 9	3	4
3	4041 80	24734 5	2	3
6	4068 14	24574 3	1	2
9	4102 28	24369 8	0	1

In view of the higher resolving power used by Dieke and Holtgreven, it is unnecessary to enter into further detail of fine structure analysis It may be mentioned that the system appears well in a tube containing carbon electrodes and a little hydrogen together with 30-40 mm pressure of argon, and it has also been produced under high temperature conditions in the carbon arc in hydrogen

The data suggest that one (or more) of the initial vibrational levels is considerably perturbed, although it is not possible to specify precisely which, on the evidence at present available

In conclusion, it may be mentioned that it seems just possible that the strong (0, 1) sequence of this system may be contributory to the strong condensation in cometary spectra which centres about the wave length λ4050 (*vide Monthly Notices R A S*, vol 87, p 625, 1927)

Strand, W C 2

Crystalline 'Menformon'

FOUR years ago we gave the name 'menformon' to a female sexual hormone, which name, as distinct from other denominations, included in its definition a certain degree of purity of the product The biological and chemical properties of the substance were described in detail in various communications, to which one about its influence upon the plumage of the fowl was added recently [1]

About a year and a half ago we reached a degree of purity of 10,000,000 units per gram [2] by means of methods described by us [3]

In August last Doisy presented a communication to the Physiological Congress in Boston, according to which he has obtained crystals containing 8,000,000 units per gram Recently Butenandt described crystals again of the same degree of purity [4] Since this substance is not purer than that previously described by us, the giving of a special name to the crystalline hormone, 'progynon', seems unnecessary

Recently Dr J R Katz was kind enough to control our own preparations by means of X ray spectrography and found the structure undoubtedly to be crystalline Since last June we have obtained more of the substance partially purified by methods based on the idea that menformon is acidic in character With these larger quantities we have now succeeded in obtaining macro crystals in the form of colourless platelets, similar to those described by Doisy and by Butenandt and have been able to demonstrate that these crystals yield the same X ray spectrum as our earlier preparations of the same degree of purity They could be repeatedly recrystallised out of 70 per cent alcohol

While in our earlier experiments with less pure material in a vacuum of about 0 4 mm at a temperature of 200° C, we were unable to obtain trustworthy information concerning the possibility of distillation, we have now succeeded, like Butenandt, in subliming the material at a pressure of about 0 01 mm and 130° 150° C It is uncertain whether any further purification was obtained thereby The analyses so far carried out have yielded results similar to those of Butenandt, that is, 78 61 per cent carbon, 8 25 per cent hydrogen As we were able to show several years ago on less purified preparations, the crystals are free from nitrogen, sulphur, and phosphorus Experiments of Dr Katz on the spreading of the substance in a monomolecular layer on water yielded very delicate films The degree of spreading suggests that the substance under investigation contains not more than 25 carbon atoms

We may mention that during the purification of the raw material obtained from the urine of pregnant women, other crystals are also encountered, which through all the initial phases were associated with the active substance (melting point, 235° C, carbon, 78 1 per cent, hydrogen, 11 5 per cent) The X ray spectrum of these crystals is different from that of menformon This substance contains an OH group, because it may be acetylated and the acetyl derivative saponified Crystals of this description have been recently found by Marrian [5] and characterised as an alcohol of a formula $C_{19}-C_{20}$

Whether crystalline menformon of the above mentioned purity (8 10 million units per gram) really constitutes the pure hormone, is not quite certain, in which respect we agree with the cautious expression of Doisy [6] at the Congress In spite of careful recrystallisation, adsorption of the active substance on the crystals cannot be excluded The objective reason for our doubt is that we have succeeded in three cases up to the present in producing a substance of an activity of 14,000,000 units per gram

Preparation of Œstrin

RECENT work from several laboratories strongly suggests that the œstrus producing hormone is a substance possessing weakly acidic properties If this is so, the methods in general use for the preparation and purification of the hormone, involving as they do numerous extractions with fat solvents from neutral or alkaline aqueous media, must result in great losses of

the active material This is borne out by the observation of Miss M Hill, privately communicated to me, that urine extracted as many as twelve times with ether may still contain large amounts of œstrin

If the urine is acidified before ether extraction, the yields of œstrin obtainable can be very greatly increased Three successive batches of fifty litres of urine treated in this manner yielded 2,069,000, 980 000, 1,000,000 mouse units, tested by the method recently described in the *Journal of Physiology* by Dr A S Parkes and myself The error in this method is little, if any, more than ± 10 per cent

Saponification and subsequent ether extraction of such crude ether soluble material, although effecting considerable purification, results in the loss of a great part of the total activity This loss can be minimised by saturating the saponified mixture with carbon dioxide before ether extraction (paper in press) The material obtained in this way can be further purified by extraction with ice cold acetone, extraction with ice cold 50 per cent alcohol, and finally extraction from ethereal solution with aqueous potash The active material may be extracted from this alkaline solution with ether after acidification The total loss of activity throughout the whole process of purification has been found to be approximately 40 per cent As the following table shows, practically the whole of this loss occurs in the initial saponification

	Wt (gm)	No M U	Wt 1 M U (mgm)	Yield M U per litre	Loss per cent
Total ether sol material from 50 l of urine	22	2 069 000	0 0106	41 380	
Unsap matter (after CO_2 treatment)	2 845	1 278 000	0 00223	25 560	38
Acetone sol	2 456	1 236 000	0 00199	24 720	40
50 per cent alcohol sol	0 742	1 236 000	0 000600	24 720	40
Alkali sol	0 364	1,208 000	0 000301	24 160	41 5

Similar results have been obtained with several other batches of urine

The most potent preparation of œstrin obtained by me by these methods had an activity of 8 million mouse units per gram This is of the same order of activity as the pure crystalline hormone described by Dr A Butenandt, of Göttingen, in a preliminary communication The latter, however, injects his material dissolved in oil in a single dose It is therefore somewhat difficult to compare the activity of the crystalline hormone with my obviously impure preparations

The Product of the Radioactive Disintegration of Potassium

DIE obige Mitteilung der Herren Frost (NATURE, Jan 11), deren Korrekturbogen mir durch die Freundlichkeit des Editor der NATURE zur Einsichtnahme vorgelegt wurden, interessiert mich in ganz besonderem Masse, da ich derzeit mit dem Studium der gleichen Frage beschäftigt bin

Zu den Atomgewichtsbestimmungen der beiden Autoren möchte ich mir die Bemerkung erlauben, dass es mir zu gewagt erscheint aus den mitgeteilten Analysenresultaten weitgehende Schlüsse in der so wichtigen Frage nach der Existenz eines durch radioaktive Umwandlung des Kaliums entstandenen Calciumisotops zu ziehen

Um Atomgewichts Unterschiede der Isotope experimentell festzustellen, muss man zunächst über eine zuverlässige Bestimmungsmethode, die genügende Genauigkeit garantiert, verfügen Die von den beiden Autoren angewandte Methode, Umwandlung des $CaCl_2$ in $CaBr_2$, arbeitet zwar bei richtiger Ausführung, wie ich mich bei meiner Atomgewichtsbestimmung des Radiums überzeugen konnte, sehr gut und sicher, dennoch lieferte sie hier recht unsichere Werte Beträgt doch die maximale Differenz der drei mit gewöhnlichem Calcium ausgeführten Vergleichsbestimmungen 0,1 Einheiten des Atomgewichtes, ist also fast ebenso gross wie die festgestellte Differenz der Mittelwerte der Atomgewichte der beiden Calciumproben, die nur 0,12 Einheiten erreicht

Ferner muss es nach den bisherigen Mitteilungen fraglich erscheinen, ob die beiden Calciumproben in Bezug auf chemische Reinheit vergleichbar waren, da der spektroskopische Nachweis für die Abwesenheit der schweren Calciumhomologen, Strontium und Barium, fehlt Die von den Autoren angewandte Reinigungsmethode, wiederholte Fällung des Calciumsulfats und Oxalats, habe ich bei der Herstellung meiner atomgewichtsreinen Calciumpräparate, die auch gerade jetzt in meinem Laboratorium durchgeführt wird, niemals versucht, da ich sie von vornherein für nicht ausreichend erachten muss

Bevor man zu der grundlegenden Frage nach der Existenz des aus Kalium entstandenen Calcium Isotops Stellung nehmen kann, wird man die angekündigten weiteren Versuche der beiden Autoren abwarten müssen, die mit grösseren Materialmengen ausgeführt hoffentlich zuverlässigere Atomgewichtswerte liefern werden

Preparations of Protozoa and Algæ

WISHING to get some permanent preparations of the Protozoa of West African forest pools, I have adopted a simple little technique which if not known is worth publication Two clean cover glasses are tied together back to back with thread, one end being left long They are suspended in the water with the lower edge just touching the bottom and sloping somewhat They are left for several days and then lifted out and immersed at once in alcoholic Bouin's fixative Afterwards I stain with Erlich's acid hæmatoxylin, 1 in 20 or 30 per cent alcohol, 3 hours, differentiate in 1 per cent acetic acid in 70 per cent alcohol, 1 3 hours, no counterstain being needed The cover slips may be kept tied together if desired up to the stage of dehydration Most, if not all, of the species of Protozoa and Algæ which may be seen in the fresh sample can be found excellently fixed and stained in the mounted specimen LL LLOYD

Azare, N P, Nigeria,
Nov 3

THE plan adopted by Dr Lloyd is excellent, providing always that it is not frustrated by (*a*) wind and rain, (*b*) fish, or (*c*) hungry marauders We adopted a similar plan in my tanks at Selsey when we were studying the bionomics of *Verneuilina polystropha* and *Massilina secans* We hung cover slips (*a*) vertically, and (*b*) horizontally close against the sides of the tanks, and they collected satisfactory gatherings of 'primordials' and very young tests I do not think it was an original operation, for I seem to remember having got the idea from something I had read EDWARD HERON ALLEN

The 'Wave Band' Theory of Wireless Transmission

By Sir AMBROSE FLEMING, F R S

IN scientific history we meet with many examples of scientific theories or explanations which have been widely adopted and employed, not because they can be proved to be true but because they provide a simple, easily grasped, plausible explanation of certain scientific phenomena The majority of persons are not able to see their way through complicated phenomena and so thankfully adopt any short cut to a supposed comprehension of them without objection

Ease of comprehension is not, however, a primary quality of Nature, and it does not follow that because we can imagine a mechanism capable of explaining some natural phenomenon it is therefore accomplished in that way There is a widely diffused belief in a certain theory of wireless telephonic transmission, and also of television, that for securing good effects it is necessary to restrict or include operations within a certain width of 'wave band' But although this view has been very much adopted there is good reason to think that it is merely a kind of mathematical fiction and does not correspond to any reality in Nature

Let us consider how it has arisen We send out from all wireless telephone transmitters an electro magnetic radiation of a certain definite and constant frequency expressed in kilocycles Thus 2LO London broadcasts on 842 kilocycles This means that it sends out 842,000 electric vibrations or waves per second Every broadcasting station has allotted to it a certain frequency of oscillation and it is not allowed to depart from it

It is like a lighthouse which sends out rays of light of one pure colour or an organ which emits a single pure musical note For most broadcasting stations this peculiar and individual frequency lies somewhere between a million and half a million per second, though for the long wave stations like Daventry it is so low as 193,000 or 193 kilocycles

When we speak or sing or cause music to affect the microphone at a broadcasting studio the result is to cause the emitted vibrations, which are called the *carrier waves*, to fluctuate in height or wave amplitude, but does not alter the number of waves sent out per second It is like altering the height or size of the waves on the surface of the sea without altering the distance from crest to crest which is called the wave length

Suppose the broadcasting station emits a carrier wave of frequency n and let $p=2\pi n$ Then we may express the amplitude a of this wave at any time t by the function $a=A\sin pt$ where A is the maximum amplitude If on this we impose a low frequency oscillation due to a musical note of frequency m and let $2\pi m=q$, then we can express the modulated vibration by the function

$$a=A\cos qt\sin pt$$

But by a well-known trigonometrical theorem this is equal to

$$\frac{A}{2}\left\{\sin(p+q)t+\sin(p-q)t\right\},$$

and thence may be supposed to be equivalent to the simultaneous emission of two carrier waves of frequency $n+m$ and $n-m$

If the imposed note or acoustic vibration is very complex in form, then in virtue of Fourier's theorem it may be resolved into the sum of a number of simple harmonic terms of form $\cos qt$, and each of these may be considered to be equivalent to a pair of co-existent carrier waves Hence the complex modulation of a single frequency carrier wave might be imitated by the emission of a whole spectrum or multitude of simultaneous carrier waves of frequencies ranging between the limits $n+N$ and $n-N$, where n is the fundamental carrier frequency and N is the maximum acoustic frequency occurring and $2N$ is the width of the wave band This, however, is a purely mathematical analysis, and this band of multiple frequencies does not exist, but only a carrier wave of one single frequency which is modulated in amplitude regularly or irregularly

If the sounds made to the microphone at the broadcasting station are very complex, such as those due to instrumental music or speech, then in virtue of this mathematical theorem the very irregular fluctuations in amplitude of the single carrier wave can be imitated if we suppose the station to send out simultaneously a vast number of carrier waves of various frequencies lying between certain limits called the "width of the wave band"

This, however, is merely a mathematical artifice similar to that employed when we resolve a single force or velocity in imagination into two or more component forces Thus, if we consider a ball rolling down an inclined plane and desire to know how far it will roll in one second, we can resolve the single vertical gravitational force on the ball into two components, one along the plane and one perpendicular to it But this is merely an ideal division for convenience of solution of the problem, the actual force is one single force acting vertically downwards Similar reasoning is true with regard to wireless telephony What happens, as a matter of fact, is that the carrier wave of one single constant frequency suffers a variation in amplitude according to a certain regular or irregular law There are no multiple wave lengths or wave bands at all

The receiver absorbs this radiation of fluctuating amplitude and causes the direct current through the loud speaker to vary in accordance with the fluctuations of amplitude of the carrier wave, the carrier wave vibrations being rectified by the detector valve

The same thing takes place in the case of wireless transmission in television The scanning spot passes over the object and the reflected light falls on the photoelectric cells and creates in them a direct current which varies exactly in proportion to the intensity of the reflected light This photoelectric current is employed to modulate the amplitude of a carrier wave, and the neon lamp at the receiving end translates back these variations of carrier wave

amplitude into variations in the cathode light of the neon tube

There is neither in wireless telephony nor in television any question of various bands of wave length There is nothing but a carrier wave of one single frequency which experiences change of amplitude The whole question at issue then is, What range in amplitude is admissible ?

In the case of television it is usual for critics of present achievements to say that good or satis factory television cannot be achieved within the limits of the nine kilocycle band allowed But there is in reality no wave band involved at all It is merely a question of what change in amplitude in a given carrier wave can be permitted without creating a nuisance

It is something like the question How loud can you whisper to your next neighbour at a concert or theatre without being considered to be a nuisance ? People do whisper in this way, and provided not too loudly, it is passed over But if anyone is so ill mannered as to speak too loudly he is quickly called to order, or turned out

It is, however, not an easy thing to define a limit to wave amplitudes They are measured in micro volts per metre and are difficult to measure But a wave length is easy to define in kilocycles or in metres, and hence the method has been adopted of limiting emission to an imaginary band of wave lengths which, however, do not exist

The definition is imperfect or elusive It is something like the old fashioned definition of metaphysics as " a blind man in a dark room groping for a black cat which isn't there " Similarly, the supposed wave band is not there All that is there is a change, gradual or sudden, in the amplitude of the carrier wave It is clear, then, that sooner or later we shall have to modify our code of wireless laws

We have no reason for limiting the output of our broadcasting stations to some imaginary wave band of a certain width, say nine kilocycles or whatever may be the limiting width, but we have reason for limiting the range of amplitude of the carrier waves sent out

Some easily applied method will have to be found of defining and measuring the maximum permissible amplitude of the carrier waves as affected by the microphone or other variational appliance It may perhaps be thought that an unnecessary fuss is here being made on what may be regarded as simply a way of explaining things, but experience in other arts shows how invention may be greatly retarded by unessential official restrictions Consider, for example, the manner in which mechanical traction was retarded in Great Britain for years by ridiculous regulations limiting the speed of such vehicles on highway roads The only restrictions that should be imposed are those absolutely necessary in the interests of public safety or convenience, and all else tend to throttle and retard invention and progress

The Growth of Education in India [1]

IN 1928 the Indian Statutory Commission appointed an Auxiliary Committee to inquire into the growth of education The Committee's views are now made public as an Interim Report of the Simon Commission The Committee consisted of six members, of whom three are Indians The minute of their appointment indicated that the Commission is primarily concerned with education in British India as bearing upon political and constitutional conditions and potentialities of progress The Committee realised the limitations thus laid upon it, but had difficulty in confining itself to a consideration of the subject in this aspect only So far, however, as this aspect is concerned, the result of the Committee's investigations, regarded as an index of administrative progress under the reformed constitution, is sufficiently disturbing

" Throughout the whole educational system ", runs the Committee's Report, " there is waste and ineffectiveness In the primary system, which from our point of view should be designed to produce literacy and the capacity to exercise an intelligent vote, the waste is appalling So far as we can judge, the vast increase in numbers in primary schools produces no commensurate increase in literacy, for only a small proportion of those who are at the primary stage reach Class IV, in which the attainment of literacy may be expected

The wastage in the case of girls is even more serious than in the case of boys "

[1] Indian Statutory Commission Interim Report of the Indian Statutory Commission (Review of Growth of Education in British India by the Auxiliary Committee appointed by the Commission), September 1929 (Cmd 3407) Pp xxxiii+401 (London H M Stationery Office, 1929) 4s net

Out of the meagre percentage (4 26) of the total population who are receiving instruction in recognised institutions, how many will retain any traces of literacy in after life ? Nor is this all The average pay of a primary school teacher in Bengal is about thirteen shillings a month, in only two provinces are more than half of the primary teachers trained, and, despite the increased number of institutions, the inspecting staff has in recent years been reduced In the light of these facts, the Committee's approval of a policy of consolidation and improvement rather than of diffusion is less surprising than the declaration that the adoption of compulsion is important and urgent as an effective means of checking the wastefulness of the present system

The Committee views the condition of secondary education with greater complacency—a complacency which is not shared by one of its members, Sir Amherst Selby Bigge The average annual cost of a pupil in a secondary school in Bengal is forty five shillings In the same province only twenty per cent of the secondary teachers are trained The curriculum is narrow and, together with the teaching, is dominated by the matriculation

examination From Bombay (where such schools are maintained at a far higher cost than in Bengal) it is reported that "with every increase in the numbers of those taking secondary education there is a fall in the standard of efficiency, owing chiefly to the fact that lower and lower strata are being tapped, and the majority of those who pass the school-leaving examination are altogether unfit for higher studies" The Committee endorses this last criticism when it comments adversely on the inadequate qualifications of high school students who enter upon university courses, "a low standard of university work means a low standard of school work" It admits that there are grave defects in the organisation of secondary education It considers that there has been an advance in some respects, but the reader is tempted to ask from what level, and by what gauge, the progress is to be measured

On the subject of higher work in the universities, the Report says that lists of original study recently published by university teachers and students and by institutions like the Indian Institute of Science at Bangalore, the Jagadis Bose Institute, and the Government Research Departments, show that a considerable advance has been made The research carried out, both in arts and in science, at the University of Dacca is specially mentioned The growth of honours schools and of post graduate courses in the universities generally is regarded as a welcome sign But it is inevitable that an inquiry into education as a factor in the creation of good citizens should deal mainly with the qualifications of the average product of the universities "There are unmistakable indications", says the Report, "that the standards in some of the universities are not satisfactory" Indeed, signs of deterioration are observed "There is no evidence of any improvement in entrance standards between 1918–19 and 1924–25, yet the number of passes at the B A and B Sc degree examinations rose in those years from 50 per cent to over 70 per cent" Some of the witnesses asserted that "the student of the present day is not equal, either in the width of his information or in the range of his interests, to the student of an older generation" It is interesting to find this view borne out by the "Ninth Quinquennial Review of Indian Education", the appearance of which synchronised with that of the Committee's Report This review, commenting on the subordination of teaching to examination, says that "it is still rare to find in any candidate, however proficient he may be in the subjects which he offers for examination, any evidence of that background of wider interest which can only be acquired by general reading and observation outside his prescribed course of study" In confirmation of this, answers are quoted which were given by fifty-five graduates of one of the universities to questions asked in a simple paper on general knowledge Among the astonishing results, fifteen of these graduates recommended charms and incantations as a cure for snake bite

Defective teaching in secondary schools, easy admission to colleges and the tyranny of examinations are obvious causes of this state of affairs The remedy is less obvious The Commission (known as the Sadler Commission) which was appointed in 1917 to inquire into the affairs of the University of Calcutta, made two admirable suggestions One was the relegation of the first two years of college instruction (called the Intermediate stage) to separate institutions organised less on collegiate than on school lines The other was the creation of a new type of unitary teaching and residential university In Calcutta itself these proposals fell on deaf ears Elsewhere (notably in the United Provinces) attempts have been made to give effect to them in a greater or less degree The "Quinquennial Review" says that but little has been accomplished in respect of the former of these recommendations—the establishment of Intermediate Colleges—and that the experiments are not on the whole very hopeful The Committee accounts for this failure by the fact that in many cases these institutions have not been established under the conditions recommended by the Sadler Commission The second suggestion is in part responsible for the large increase in the number of universities of British India—from five in 1915 to fifteen to day But of these fifteen only five are unitary, and the "Quinquennial Review" points out that the two universities created during the last quinquennium have reverted to the affiliating type and that the University of Rangoon also has assumed affiliating functions

The Committee justly remarks that the affiliating university is likely to remain for many years to come, and it may be noted as a sign of grace that it now generally participates in the work of higher teaching But it might have been hoped that the establishment of unitary universities, with their greater concentration of teaching effort and of social amenities, would gradually reduce the number of scattered colleges (often ill staffed and ill equipped) which prepare the majority of students for the examinations of an affiliating centre Instead of this, there has been a new growth of these affiliating and examining centres, with the danger, as the Committee more than hints, of unwholesome competition, and the number of affiliated arts colleges has actually risen from 152 in 1922 to 232 in 1927 The task of university reform in India is Sisyphean Well may the Committee ask whether "the time has not come when all efforts should be concentrated on improving university work, on confining the university to its proper function of giving good advanced education to students who are fit to receive it, and, in fact, to making the university a more fruitful and less disappointing agency in the life of the community"

Other points in this Report are no less disquieting The Central Advisory Committee and the Bureau of Education, which constituted practically the last links between the Government of India and educational problems, have been abolished The Committee regrets their disappearance, for, though the reforms have favoured expansion,

"much of that expansion has been on ill considered lines and neglectful of the proposals made by the Government of India previously to the reforms" Education, as a transferred subject, is now in the hands of ministers in the provinces A tribute is paid to the zeal and ability which these ministers bring to bear upon their task But the position of a minister is unstable He cannot easily escape from adverse influences It was represented to the Committee that in some provinces he had exercised pressure on the Director of Public Instruction in the matter of appointments and promotions on political and irrelevant personal grounds Moreover, he has to work through various agencies, such as local bodies, which, the report notes as a distressing feature, "have in many instances gravely abused their powers for political and other purposes" He is likewise largely dependent on the services which deal directly with education The Indian Educational Service, 'with its fine traditions of integrity and devotion to duty", is moribund The Committee declares that its progressive extinction, accompanied by the failure to reconstitute the provincial Services, "has been disastrous to the organisation of Indian education" "The number of fully qualified men and women, competent to hold the higher posts in the Department, has become totally inadequate in every province"

The attitude of the Committee has clearly been sympathetic But the studied restraint of the report serves to emphasise some of the conclusions into which facts have forced its members If literacy is a desirable qualification in the voter, an expansion of mass education which is (in the words of the report) "so largely ineffective as scarcely to influence the advance of literacy at all in the sense of increasing the proportion of literates to the population" cannot result in the formation of a competent electorate Nor, however brilliant may be the exceptional scholar, does a top heavy superstructure of higher education, coupled with relaxation of the standards of admission and too often with unemployment after completion of the course, promise well for the production of sound representatives and officials Above all, this narrative of educational work during the past few years indicates a fatal tendency to loosen the framework on which the whole fabric depends for support H SHARP

Bochart de Saron, 1730–1794

WHEN Herschel, in April 1781, announced the appearance of a new body in the heavens, nowhere did the news create greater interest than in France, where Lalande, Mechain, Lemonnier, Laplace, and Bochart de Saron attempted to discover the orbit in which the body moved Based on the supposition that it was a comet, the investigations all failed until Bochart de Saron, on May 8, 1781, announced that the so called comet was in reality much farther from the sun than had been thought This was the first glimmering of light on the perplexing subject which eventually led to the discovery that Herschel's 'comet' was a new planet, to which he assigned the name Georgium Sidus, but was afterwards designated Uranus

Jean Baptiste Gaspard Bochart de Saron, born on Jan 16, 1730, two hundred years ago, was as distinguished in law as in science He served as president of the Parliament of Paris, and at his seat in Champagne had an observatory partly furnished by Ramsden It is said, also, that a duplicate of Ramsden's dividing machine was introduced into France by him, concealed in the pedestal of a table Especially interested in comets, he became a member of the Paris Academy of Sciences, and it was he who paid for the printing, in 1784, of Laplace's "Théorie du mouvement et de la figure des planètes" But, ten years later, neither his eminence as an astronomer or as a lawyer could save him from the fury of the Terror, and he perished beneath the guillotine

The king had fallen in January 1793, Marie Antoinette in October, the academies had all been suppressed, the scaffold had alike claimed Bailly, Madame Roland, and Danton, and executions could be counted by the hundred On April 13, 1794, nineteen were condemned, on April 18 a further seventeen, mostly of the nobility, and on April 20, Bochart de Saron and twenty four of his fellow ex presidents and counsellors of the Parliaments of Paris and Toulouse suffered It was to see this 'batch' tried that the Auvergnat carpenter, Trinchard, wrote the invitation, "If you are not alone and the journeyman is working, you can, my dear wife, come to the court to see twenty four gentlemen, all of them former presidents or counsellors passed in judgment I advise you to get something to eat before coming, as we shall not have finished before three o'clock"

There was never any doubt of the finding of the court, and while it was still sitting Fouquier was ordering the tumbrils and the escort Presiding over the court which condemned Bochart de Saron was the notorious Coffinhal, who a few days later, when trying the Farmers General, immortalised himself by replying to the great Lavoisier, who had asked for a delay in order to allow him to conclude an experiment, The Republic requirés neither savants nor chemists, the course of justice cannot be suspended" For three months longer the guillotine continued to rob France of some of her greatest minds With the fall of Robespierre on July 28, the nation breathed again, and the year which saw the death of Condorcet, Bochart de Saron, and Lavoisier, also saw the foundation of the great institutions, the École Normale, the École Polytechnique, and the Conservatoire des Arts et Métiers, while the year 1795 saw the inauguration of the famous Institut de France

Obituary.

Dr Samuel Rideal

Samuel Rideal was born in London in 1863 His father was John Rideal He obtained a scholarship at Dulwich College, 1875–1878 For a short time he studied at the Royal School of Mines, but afterwards went to University College, London, where, in 1883, he became assistant to Dr A W Williamson He retained this post for a year or two under Sir William Ramsay, but in 1889 became lecturer on chemistry at St George's Hospital Medical School He was a brilliant student, and in 1884 took the degree of bachelor of science at the University of London, with first class honours, and a University scholarship in chemistry Two years later he received the degree of doctor of science, his subject being inorganic chemistry In 1888 he was elected a fellow of University College, London Already in 1878 he had become a fellow of the Institute of Chemistry, upon the council of which he served during the years 1899–1902

About the year 1890, Rideal became public analyst for Chelsea, and was also, for a short time, public analyst for Lewisham He set up a consulting practice at 28 Victoria Street, S W, and retained an active interest in the work for thirty five years He married Lilla, daughter of the late Samuel Keightley, of Bangor, Co Down, and sister of Sir Samuel Keightley, barrister and novelist Dr Rideal's son, Eric K Rideal, is Humphrey Owen Jones lecturer in physical chemistry at Cambridge, and fellow of Trinity Hall He has taken up his father's work in conjunction with Mr A Sciver

While at University College, Rideal published several researches in pure chemistry, such as the action of ammonia on chromyl dichloride, on tungsten compounds, and on the halogen compounds of boron A new volumetric method for the estimation of nitrous acid depending upon the conversion of an acid solution of aniline into diazo benzene was published by Arthur G Green and S Rideal in 1884

Dr Rideal became a recognised authority on the disposal and disinfection of sewage, the purification of water and sanitation generally His book on "Sewage and the Bacterial Purification of Sewage" went through three editions, while that on "Water and its Purification" published in 1897, had a new edition in 1901 With his son, Dr Eric Rideal, he published "Public Water Supplies" in 1914 The Rideal Walker method for determining the antiseptic value of disinfectants is widely used Rideal also studied carefully the use of electrolytic chlorine and of ozone in the purification of sewage He was well known as an expert witness in the courts and gave evidence in a large number of Parliamentary inquiries

Rideal's indefatigable energy in overcoming difficulties and his frank manner gained the confidence of those who had to work with him To the great sorrow of his many friends, his health gave way, so that he had to take a prolonged rest He died at Hartley, in Southern Rhodesia, on Nov 13 last, at the age of sixty-six years

Dr A N A Nalepa

Dr August Nemesius Alfred Nalepa, the well-known acarologist, of Baden, near Vienna, died after a short illness on Dec 11 last Nalepa was born at Versecy, in Hungary, on Dec 15, 1856 He was educated at the University of Vienna and later joined the staff and became assistant zoologist at the University

Nalepa commenced to study the gall mites (Eriophyidæ) in 1880, and seven years later he published his fundamental and unique work entitled "The Anatomy of the Phytoptera" The gall mites are considered to be the most primitive animals of the order Acarina, they are all microscopic in size and are entirely herbivorous in their habits Nalepa studied them mainly from a systematic point of view, and as a result of his researches more than four hundred new species have been described He was a prolific writer, and his publications in relation to gall mites number about one hundred Of these, his works entitled 'Eriophyidæ", in "Das Tierreich" (Berlin, 1898), and "Eriophyiden, Gallenmilben", *Zoologica*, 61 (Stuttgart, 1910), are widely known, and are still recognised as the standard works on the subject

For prominent services rendered to education and scientific research Nalepa was honoured with the Emperor Franz Joseph Order and also the title of State Councillor He was very generous, and delighted in assisting and advising other students engaged in research on the Eriophyidæ, and his immense knowledge of the group, together with sound criticism, always proved of great value to those who had the pleasure of corresponding with him

Nalepa took an active interest in gall mites until the last, and was about to publish a new paper in collaboration with the present writer on 'The Habits of Gall Mites" at the time of his death He possessed a magnificent collection of gall mites contained in small glass vials This collection is unique, and will in all probability be presented to the trustees of the Vienna Museum of Zoology

A M Massee

Dr Wilhelm Maybach

The death of Dr Wilhelm Maybach at Stuttgart on Dec 29 removes the last of the four great German pioneers whose names will always be associated with the perfection of the internal combustion engine and its application to road transport Nicolas Otto, who died on Jan 26, 1891, Gottlieb Daimler, who died on Mar 6, 1900, Karl Benz, who passed away in April last, and Maybach, all made important contributions to this subject, and to their names might be added that of Eugen Langen, 1833-1895 Just as Maybach for many years was connected with Daimler, so seventy years ago Otto had found in Langen a most able collaborator and partner

Otto began his long struggle with gas engine difficulties in 1854, with Langen in 1867 achieved partial success, and then ten years later, on Aug 4, 1877, took out his great patent for the four stroke

engine so widely used to-day Moreover, in 1872, the partners founded the Gasmotorenfabrik Deutz Aktiengesellschaft, near Cologne, in which both Daimler and Maybach worked

The partnership of Daimler and Maybach dates from the 'eighties, and Daimler in 1884 invented the light high speed spirit engine which the following year was applied to road carrriages by Karl Benz The first motor car imported into England, as also the first imported into the United States, was a Benz In the subsequent improvements of the 'nineties, Daimler and Maybach both had a large share, and the Mercedes car exhibited by Maybach at the Paris Exhibition in 1900 was named after Daimler's daughter

Daimler dying in 1900, Maybach took over the direction of the Daimler works, retiring in 1907 His son's work for Count Zeppelin, however, led to his taking up active work again, and for many years he has been engaged with the management of the Maybach Motorenbau G m b H at Friedrichshaven, the first subsidiary company of the Zeppelin works A fine example of a Maybach airship engine is to be seen in the Science Museum at South Kensington, and it may be recalled that the 530 h p engines with which the airship *Graf Zeppelin* is equipped were supplied by the firm Maybach was born at Heilbron on Feb 9, 1846, and was thus in his eighty fourth year

WE regret to announce the following deaths

Major P G Craigie, C B, formerly assistant secretary to the Board of Agriculture and Fisheries, who was president of the Royal Statistical Society in 1902 and president of Section F (Economic Science and Statistics) at the Bradford meeting (1900) of the British Association and of the Sub Section of Agriculture at the Winnipeg meeting (1909), on Jan 10, aged eighty six years

Dr S Z de Ferranti, F R S, president in 1910 and 1911 of the Institution of Electrical Engineers, on Jan 13, aged sixty five years

Prof Henry D Hooker, associate professor of horticulture at the University of Missouri, known for his work on the chemical composition of fruit plants and on plant reactions, on Oct 26, aged thirty seven years

Mr Maximilian Mannaberg, well known in the iron and steel industry, who was one of the founders of the British Engineering Standards Association and also of the Institute of Fuel, on Dec 18, aged seventy-two years

Sir Thomas Matthews, formerly engineer in chief to Trinity House, who was well known in connexion with the design and equipment of lighthouses, on Jan 13, aged eighty years

Mr Henry Nehrling, collaborator in the Bureau of Plant Industry of the U S Department of Agriculture, known for his work in horticulture and ornithology, on Nov 22, aged seventy six years

Mr E A Pinchin, public analyst to City of London and the Boroughs of Camberwell and Islington, on Dec 23, aged fifty five years

News and Views

REPORTS appeared in the daily Press last week announcing the recent death of Prof A A Michelson, the distinguished physicist of the University of Chicago We are happy to be able to state, on the authority of a cablegram from Science Service, of Washington, D C, in reply to an inquiry by us, that these reports are incorrect and that Prof Michelson is on his way to enjoy a holiday in Bermuda after his recent illness A detailed account of Prof Michelson's work was given by Sir Oliver Lodge in NATURE of Jan 2, 1926, when Prof Michelson was added to our series of Scientific Worthies It is stated in *Science* of Dec 27, 1929, that he has resigned his position in the University of Chicago as head of the department of physics, and that after his visit to Bermuda, he intends to go to Pasadena, California, to carry out further work on the velocity of light We are sure that scientific workers throughout the world will join with us in congratulating Prof Michelson that he has survived his obituary notice, and also in wishing him many years of health and strength to add to those fundamental measurements for which the world is already indebted to him

SUGGESTIONS have recently appeared in the Press to the effect that the Middlesex County Council is contemplating acquiring Syon Park, which is situated on the banks of the Thames immediately opposite the Royal Botanic Gardens, Kew, for the development of a sewage disposal scheme Local opposition was quickly aroused, while on Jan 9, at a well attended meeting, the Linnean Society of London passed the resolution ' That the Society views with the utmost concern and regret the reported proposal in regard to the grounds of Syon House" The meeting requested the president and secretaries to make public this resolution and to express at greater length the sentiments evidenced in the decision The Society deplores the proposal to acquire Syon Park for sewage disposal and earnestly hopes that nothing will be done to mar the singular beauty of the Syon reach of the River Thames It considers that Syon Park should be safeguarded from any form of spoliation or 'improvement' such as a riverside embankment which would be inimical to the wild river life for which this is one of the few remaining localities near London, and in which lovers of Nature find their interest and their duty

IT is now just over a century since Lamarck died (see NATURE, Dec 14, 1929, p 922), and his remains lie in an anonymous grave in Montparnasse cemetery, Paris The only memorial which France had of him was the house where he was born, the home of his ancestors, at Bazentin, a small village of the Somme, not far from Albert For four years, Bazentin was in the zone of the Somme fighting, and the locality is well known to many who served in the British Army on the Western Front Of Lamarck's house, only a few scattered bricks and blackened stones are now left The Société Linnéenne du Nord de la France has therefore decided to raise a fund with the view of erecting, on the site of the old house, a memorial worthy of Darwin's precursor This memorial will

stand in the middle of a garden, in which the plants grown will be the botanical species especially studied by Lamarck or named after him by other botanists Lamarck belongs not to Picardy or to France but to the whole world, his work on classification made possible noteworthy advances in biology, and his views on evolution are still the subject of debate A memorial to him is an object in which scientific workers of all nationalities may fittingly co operate Remittances should be directed to Banque de France, succursale d'Amiens (Somme) au Compte Société Linnéenne souscription Lamarck—No 2433 All correspondence should be sent by May 15 next to M le Secrétaire Général du Comité Lamarck, 81 Rue Lemerchier a Amiens (Somme)

THE problems which face the introducer of foreign species of animals to a new country are as difficult to solve in advance as they are many The subject came before the Linnean Society recently in connexion with the proposed introduction of black buck into Ceylon, and a resolution was passed and communicated to the Colonial Office deprecating the introduction and naturalisation of wild animals or plants into new countries except after thorough study of the local conditions and possible results But even when a creature has made good in the land of its naturalisation there may still be acute differences of opinion about the economic success of the venture The introduction of the musk rat (*Fiber zibethicus*) to Europe for the sake of its fur is a case in point Dr Hjalmar Broch showed (in *Naturen*, No 1, 1929) that this species, introduced into Bohemia, has over run much of southern Europe, and has become a pest against which strong measures have been taken (see NATURE, May 18, 1929, p 775)

DR BROCH's article, and particularly his statement that the experience of southern Europe should prevent any relaxation of the law prohibiting the importation of live musk rats to Norway, has been met by a spirited protest from Ludv Munsterhjelm (*Naturen*, p 120, 1929) This author cites the experience of Finland, where the musk-rat was liberated on several small estates in two districts some years ago From neither area have reports of damage to crops been received, nor has there been any undue tendency of the creature to spread beyond its proper domain The difference appears to be traceable to topographical and climatic conditions In the warmer plains of southern Europe all the conditions favoured abundant food supply and rapid breeding, whereas the mountains of Finland, with their unsettled weather, imposed a natural check upon multiplication and dispersal Munsterhjelm considers that there is no probability of the spread of the musk rat overland to Norway, and holds that in Norway itself the musk rat might well be bred profitably and without incurring risk of damage to crops or property

ATTENTION is being directed to the possibilities of the transference of diseases, human, animal, and plant, by air routes Owing to the rapidity of air transit, an individual in the incubation stage of cholera might board an air liner in China, land at Los Angeles within two or three days, and develop the disease a day or two later, with the risk of spreading cholera far and wide Another serious event would be the introduction of yellow fever into Asia by this means When travel is slower, as by steamship, there is usually time for the disease to develop en route before the next large community is reached Aerial boarding stations for quarantine officers have already been envisaged by public health authorities, and we learn from a radio talk issued by Science Service, of Washington, D C, that the U S Public Health Service has detailed quarantine officers expressly for the inspection of air craft at the landing fields before the passengers or crew disembark

ON Jan 14, 1830, appeared the first number of *Das chemische Zentralblatt*, which at that time was also designated *Das pharmaceutische Centralblatt* The centenary of this well known reference work was marked by the delivery of an address to the German Chemical Society by Dr Maximilian Pflücke on Nov 11, 1929 The address, which is published at length in the December issue of the *Berichte der Deutschen Chemischen Gesellschaft*, deals with the early history and subsequent development of the journal The original purpose of the undertaking was to provide pharmacists with an accurate survey of the new and important facts of interest to them which were being discovered not only in Germany but also in France, England, Holland, and Italy At first the issue was fortnightly, but ever since September of the first year of publication it has appeared weekly in spite of the enormous difficulties arising from the War The extraordinary growth of the work can be gauged from the fact that the number of abstracts in the first volume amounts to about one per cent of those now appearing annually, and many of the original sources are now obsolete The first editor, Herr Gustav Theodor Fechner, was able to undertake the whole survey himself One of his earliest problems was apparently connected with nomenclature, and he decided to be guided by the system of Berzelius After several changes, the editorship passed into the hands of Prof Rudolf Arendt in 1862, who guided its destiny for about forty years So successful was the work under his direction that in 1895 the German Chemical Society decided to take over the management, and shortly after Arendt's death in 1902 the headquarters were moved from Leipzig to the newly established Hofmann Haus in Berlin

TWO replicas of 'Les Bisons d'Argile' of the Tuc d'Auduobert Cave of the Ariège district are on their way to Canada one, ordered by Dr Ami, the director of the Canadian School of Prehistory in France, for Ottawa, the other, ordered by Prof W A Parks, of the Geological Department of the University of Toronto, Canada It is well that Canada should possess replicas of that wonderful piece of Magdalenian art, modelled some twenty thousand years ago when the bison dwelt in south western France in large numbers The bison to day is a typical Canadian animal, and it is not yet extinct, nor does the Canadian Government, if we understand aright, mean the race to pass out The *bisons* represented on the clay mass

—beautifully carved and sculptured—measure as a piece of art more than two metres in length, and form a most impressive spectacle from every point of view The magic in art is well exemplified there, and it is to be regretted that, so far, no specimen of the few replicas being prepared for university or prehistoric museums is to be seen in Great Britain These replicas are being prepared under the supervision of Count Begouën of the University of Toulouse, France

MISS SYLVIA SEELEY, of the Canadian School of Pre history in France, whose able presentation of Count Begouen's views on "The Magic Origin of Prehistoric Art" appeared in the March number of *Antiquity*, has recently been co operating with him in the University of Toulouse, in the preparation of a comprehensive statement of the subject So much new material has of late been, and is every week being, discovered by different members of the Begouen family, and by others working in the Ariège (Pyrenees) caves, that unless someone brings together every once in a while the re sults obtained in synthetic form and interprets the facts obtained in the light of prehistoric science and art, much time is lost and progress retarded The work undertaken by Miss Seeley, in collaboration with Count Begouèn, promises to open new vistas in the hidden treasures of those Pyrenean caves The discovery of the grasshopper, of the owls, of the rare engravings and paintings in the Grotte des Trois Frères, near Pryòl, Ariège, are absorbing their attention, and will mark an interesting phase of prehistoric art in the light of what those discoveries themselves teach

THE University of St Andrews has planned an ambitious and admirable series of lectures under the adult education scheme for Fife and Stirlingshire The title of the course and of the 60 page 'Synopsis' published by the University Press of St Andrews, "Man and his World in the Light of Emergent Evolution," suggests the general scope of the series, but it gives no idea of the care with which the lectures have been devised and arranged to give a connected story, from the evolution of matter and the universe by way of the evolution of living things to the emer gence of mind and its products It endeavours to place in their due relationships and to give unity to the discoveries of the sciences and the developments of civilisation Each of the twenty lectures has been written by an expert, generally the professor of the particular subject at the University, and in spite of the contraction of an hour's lecture into an average of two pages, the synopsis still carries the theme through with a swing It is a pity that so excellent a course should be introduced by a preface the intellectual sufficiency of which would damp the ardour of many a modest inquirer after knowledge

A REGULAR public service of picture telegraphy be tween London and Berlin is now in operation The Siemens Carolus system has been adopted and some of the pictures we have seen transmitted in this way are extremely good, with the exception of a slight tendency to exaggerate the blacks and the whites, the results are admirable It is expected that the newspapers will be the largest users of this service It will probably be used whenever it is necessary to send architects' plans and engineering drawings as quickly as possible Cheques and legal documents with the signatures in facsimile can also be sent use fully in this way Scotland Yard will doubtless make use of it to send the photographs of 'wanted' persons to seaports so as to prevent them leaving the country Similar services already exist between Berlin and Copenhagen, Berlin and Vienna, and Berlin and Stockholm

THIS year the picture telegraphy service will be extended to Munich and other German towns and to Holland and Belgium The London to Berlin circuit is about a thousand miles long and consists of cable throughout During the experimental stage, con siderable trouble was experienced owing to inductive interference with other circuits, but this source of trouble has now been eliminated The charge for sending picture telegrams from Great Britain is at the rate of $2\frac{1}{2}d$ a square centimetre, which is equivalent to about a pound for fifteen square inches There is a minimum charge of one pound Some success has been achieved in radio picture telegraphy between Berlin and Buenos Ayres From the commercial point of view the services do not seem to be attractive, but they may nevertheless serve a useful function

Now that it is possible to communicate with nearly ninety per cent of the world's telephone stations from any one of the 1,900,000 subscribers' stations of the British Post Office, a vast amount of work has to be done in maintenance In addition, as last year there were 125,000 new subscribers, thousands of miles of new cable had to be laid In the *Electrician* for Dec 27, P E Erikson says that the rate of progress is such that one new public exchange and 1000 new telephones (including replacements) are installed for each working day of the year Fifteen new large automatic stations were completed in London last year Of the twelve next largest towns in Great Britain, five are completely converted and four are well under way An important development put into operation last year is the installation of rural auto matic exchanges Ninety exchanges have been installed providing day and night service to outlying subscribers, who would otherwise have only a limited day working When a minimum of eight subscribers is forthcoming, rural automatic exchanges are being installed Many new districts have been added in countries in which communication was already estab lished In Italy, for example, a recent installation of a carrier system provides three additional channels over an existing wire line and has greatly increased the service The new hand set which is being introduced as an alternative to the familiar pedestal pattern telephone is excellently designed Hand set telephones have been in use on the Continent for many years, but the speech transmission characteristics of these have been markedly inferior to the pedestal sets, the new hand sets have, on the other hand, superior char acteristics Successful ship to shore conversations be tween New York and the *Berengaria* up to distances of about a thousand miles were carried out during last year

A CONFERENCE arranged by the National Institute of Agricultural Botany, with the assistance of the Royal Agricultural Society of England and the National Farmers' Union, was held on Jan 8 to discuss the question of cereal synonyms and means of eliminating them Representatives of the Agricultural Seed Trade Association and of the National Association of Corn and Agricultural Merchants also took part in the conference It was agreed that it is undesirable in the interests alike of agriculturists, plant breeders, and the seed trade that stocks of wheat, barley, and oats sold for seed which are of identical origin and character should be sold under different names The name under which such stocks are sold should be that given by the original producer, with the addition of words indicating that further selection has taken place where this has been done It was also resolved that a standing committee of reference, consisting of one representative of each of the five associations and of the Cambridge University Plant Breeding Institute should be formed to investigate and report on infringements of the recommendations of the conference The secretary of the National Institute of Agricultural Botany is to act as convener of the committee of reference

THE Geological Society of London has this year made the following awards of medals and funds The Wollaston Medal to Prof A C Seward, master of Downing College and professor of botany in the University of Cambridge, in recognition of the value of his researches in stratigraphy and palæobotany, the Murchison Medal to Mr A L Hall, of the Geological Survey of South Africa, for his researches on the stratigraphy and economic geology of South Africa, a Lyell Medal to Mr F Chapman, palæontologist to the Federal Government of Australia, in recognition of his work in palæontology (especially on the Foraminifera), and of his researches on the tertiary rocks of Australia, a second Lyell Medal to Mr H B Maufe, Director of the Geological Survey of Southern Rhodesia, for his work on the geology and mineral resources of that Colony, the Wollaston Donation Fund to Mr E G Radley, of H M Geological Survey, in consideration of his work on the chemical analysis of rocks and minerals, the Murchison Geological Fund to Mr John Smith of Dalry, in recognition of his contributions to the geology and palæontology of western Scotland, the Lyell Geological Fund to Miss H M Muir Wood, in recognition of her work on the palæontology of the Brachiopoda

THE Harrison Memorial Prize Selection Committee, consisting of the presidents of the Chemical Society, Institute of Chemistry of Great Britain and Ireland, Society of Chemical Industry, and Pharmaceutical Society, has awarded the Harrison Memorial Prize for 1929 to Dr R P Linstead The prize is given for conspicuously meritorious work in any branch of chemistry, pure or applied, and is to be regarded as an exceptional distinction to be conferred upon a chemist less than thirty years of age who in the opinion of those best qualified to judge had made a notable addition to our knowledge of chemistry The presentation of the prize will be made at the annual general meeting of the Chemical Society on Mar 27

THE Darwin Medal awarded by the Royal Society in 1928 to Dr L Cockayne was presented to him on Aug 7 last at a special meeting of the Canterbury Branch of the Philosophical Institute of New Zealand, held in the Hall of the Canterbury University College, Christchurch, New Zealand, by Dr C C Farr, professor of physics in the Canterbury University College and president of the Philosophical Institute of New Zealand In the course of an address on "Darwin and After Darwin", Dr F W Hilgendorf of the Agricultural College, Lincoln, Canterbury, dwelt upon the great value and significance of the recent researches by Dr Cockayne into hybridism in the native flora of New Zealand, which have proved clearly that Nature is selecting among the members of the hybrid swarms In presenting the medal, Dr Farr remarked that Dr Cockayne is the first to gain a Royal Society Medal by work done entirely in New Zealand Dr Cockayne, in his reply, spoke of his early interest in the plants of his native Yorkshire, and told how the late Mr Robert Brown, the well known bryologist of Christchurch, had advised him, when he first began to work upon the flora of New Zealand, "to leave the authorities alone and go to the plants themselves" Outlining his own work, Dr Cockayne said that he had published 155 botanical papers, all of which touch upon and illustrate variation in plants Only a few years ago, our knowledge of hybrids in New Zealand was quite meagre, whereas now there are known to exist no less than 360 'hybrid swarms' In his opinion, the flora of New Zealand offers a magnificent laboratory for the study of evolution, and he expressed the hope that its problems will ultimately be solved by some worker born and bred in New Zealand itself On behalf of the Philosophical Institute of Canterbury, Mr R M Laing congratulated its only honorary member, Dr L Cockayne, on the award of the Darwin medal He said that Dr Cockayne's work, apart altogether from its scientific value, has resulted in much knowledge of value to horticulture, agronomy, and forestry

IN a further despatch to the *Times*, Sir Hubert Wilkins has added some details about his flight to Charcot Island The most easterly point of the island is in long 73° W, and the latitude of the north coast is five miles south of its charted position The flight evidently confirms the existence of Stefansson Strait between Graham Land and Hearst Land and extends the islands of the Finley group to long 70° W No further information is available regarding Hearst Land and its relation to the Antarctic continent It appears, however, to be Sir Hubert Wilkins' intention to travel by steamer along the pack ice to about long 100° W, making flights to the coast at various points He believes that he may be unable to make his contemplated flight to the Ross Sea owing to the lack of a suitable taking off field in the far south

THE seventh annual meeting of British zoologists was held on Jan 11 in the rooms of the Zoological Society of London, by kind permission of the council of the Society Prof Stanley Gardiner opened a dis-

cussion on the possibility of rendering the zoological experts of one university available for special instruction to the advanced students of another university The committee presented a report on the syllabus of biology in schools, urging the importance of a grounding in animal biology as a preparation for citizenship Mr James Gray recounted the difficulties of importing scientific cinema films and scientific apparatus, it was decided to appoint a subcommittee to consider the hindrances offered to scientific research by the present Customs regulations On the motion of Lord Rothschild, the meeting expressed disapproval of any proposal to convert the existing nature reserves in Great Britain into national parks Dr C M Yonge reported the proceedings of the Barrier Reef Expedition and was congratulated on his success

WE have received Parts 71 72 (combined) of "Type Ammonites", which bring to a conclusion this work started by the late Mr S S Buckman (as "Yorkshire Type Ammonites") a little more than twenty years ago The whole work includes more than 1000 plates, figuring very nearly 800 species of Jurassic ammonites No plates appear in the final part, which, except for the completion of the author's text on the opening page, consists entirely of tables and notes compiled by the editor, Dr A Morley Davies Chief among these is a complete list of the figured species arranged in order of geological sequence according to the detailed hemeral scheme proposed by the author There are also indexes of generic and specific names, bibliographic details, etc This final part is published by the executors of the late S S Buckman, at Southfield, Thame, England (price £1) We understand that a limited number of complete copies of the whole work (Vols 1 7) are still available (price £36), and that incomplete sets can be completed provided they include Vol 3

IN the *Times* of Jan 11 was the account of the sale by auction of the famous mountain landmark in south eastern France, the Puy de Dôme, famous as the scene of Pascal's great experiment with the barometer It was a month after Torricelli's death that Pascal first proposed the experiment of carrying a barometric tube up a mountain and noting the variation Being himself in the north of France, he wrote to his brother in law, Périer, in November 1647, but the experiment was not carried out until Sept 9, 1648, when Périer and his companions found that while at the base of the mountain the mercury stood at 26 in, at the summit it had fallen to 23 in The Puy de Dôme was also one of the heights ascended by Guettard and Malesherbes prior to the former reading his paper on "Certain Mountains in France which have once been Volcanoes" to the Paris Academy of Sciences on May 10, 1752 Last year a syndicate attempted to buy the summit to make it a tourist resort, but the peasant proprietors defeated the attempt, and they have now apparently by a bid of 122,000 francs outbid the Department, hoping thereby to enhance its value still further

SIR RICHARD GLAZEBROOK, formerly Director of the National Physical Laboratory, has been elected an honorary member of the Institution of Electrical Engineers

LORD BLEDISLOE, whose appointment as Governor-General of New Zealand was referred to in our issue of Dec 7, 1929, p 887, has been made Knight Grand Cross of the Most Noble Order of St Michael and St George (G C M G)

A MEMORIAL plaque to the late Sir William Glyn Jones, formerly secretary of the Pharmaceutical Society of Great Britain, who died on Sept 9, 1927, will be unveiled in the Society's examination hall by the Right Hon Christopher Addison, on Wednesday, Feb 5, at 3 P M

THE Secretary of State for the Colonies has appointed Dr Drummond Shiels, M P, Parliamentary Under Secretary of State for the Colonies, to succeed Mr William Lunn, M P, as chairman of the Advisory Committee on Education in the Colonies and of the Colonial Advisory Council of Agriculture and Animal Health, and also as chairman of the Colonial Medical Research Committee

THE Henry Saxon Snell prize of the Royal Sanitary Institute was founded to encourage improvements in the construction or adaptation of sanitary appliances, and is to be awarded by the Council of the Institute at intervals of three years The prize in the year 1930 will consist of fifty guineas and the medal of the Institute, and is offered for an essay on "Improvements in the Sanitary Provisions of Schools" Essays should not be longer than 5000 words and typewritten, must be delivered on or before Aug 30 next, addressed to the Secretary of the Royal Sanitary Institute, 90 Buckingham Palace Road, London, S W 1, from whom further particulars may be obtained

As already announced, the meeting of the British Association this year will be held in Bristol on Sept 3–10, when Sir Thomas Holland will be succeeded in the presidential chair by Prof F O Bower The presidents and recorders of the Sections will be as follows A (Mathematical and Physical Sciences) Dr F E Smith, Mr W M H Greaves, Royal Observatory, S E 10 B (Chemistry) Prof G T Morgan, Prof C S Gibson, Chemical Department, Guy's Hospital Medical School, S E 1 C (Geology) Prof O T Jones, Mr I S Double, Department of Geology, University, Liverpool D (Zoology) Dr W T Calman, Mr G Leslie Purser, University, Aberdeen E (Geography) Prof P M Roxby, Mr R H Kinvig, 36 Oakfield Road, Selly Park, Birmingham F (Economics) Prof T E Gregory, Mr R B Forrester, Inverey, Somerset Road, New Barnet, Herts G (Engineering) Sir Ernest Moir, Mr J S Wilson, 49 50 Parliament Street, S W 1 H (Anthropology) Dr H S Harrison, Miss R M Fleming, Marine Terrace, Aberystwyth I (Physiology) Prof H S Raper; Dr M H MacKeith, Magdalen College, Oxford J (Psychology) Prof C W Valentine, Dr Shepherd Dawson, Hazel Bank, Thorn Road, Bearsden, Dumbartonshire K (Botany) Dr A W Hill, Prof W Robinson, Botanical Department, University College, Aberyst-

wyth L (Education) Right Hon Lord Eustace Percy, P C, Mr G D Dunkerley, 29 Gordon Square, W C 1 M (Agriculture) Dr P J du Toit, Prof G Scott Robertson, Ministry of Agriculture, Welling ton Place, Belfast

THE following appointments have recently been made by the Secretary of State for the Colonies Mr A G G Hill, botanist, Nigeria, to be plant breed ing officer (senior geneticist), Mauritius, Mr N Humphrey, to be agricultural officer, Kenya, Mr L. R Doughty, to be geneticist, East African Agricultural Research Station, Amani, Tanganyika Territory, Mr J P Mead, personal assistant to the conservator of forests, Malaya, to be director of forestry, Malaya, Mr J N Oliphant, conservator of forests, British Honduras, to be deputy director of forestry, Malaya

THE afternoon lectures at the Royal Institution will be resumed on Jan 21 at 5 15, when Dr F W Aston will begin a course of three lectures on Tuesday afternoons on isotopes, on succeeding Tuesdays there will be four lectures by Sir William Bragg on X ray determination of the structure of cellulose and similar substances, and four by Dr Charles Singer on the passage from medieval to modern science On Thursday afternoons, beginning on Jan 23 at the same hour, there are to be two lectures by Dr H A Harris on the growth of children in health and disease, one on Feb 6 by Dr R L Smith Rose on radio direction finding by transmission and reception, and two by Mr T A Joyce on architecture and the industrial arts of Pre Spanish America The Saturday afternoon lectures at three o'clock will include four by Sir Ernest Rutherford on atomic nuclei and their structure Sir William Bragg will give the first Friday evening discourse on Jan 24, on cellulose in the light of the X rays Succeeding discourses will probably be given by Lord Rayleigh, Dr Leonard Hill, Prof A F Pollard, Prof G I Taylor, Mr C Tate Regan, Prof G Elliot Smith, Mr Seton Gordon, Sir Ernest Ruther ford, and others

MOVEMENTS attributed to an earthquake reported to have been felt in Brittany were recorded at Kew Observatory on Jan 9 The first onset was at 19 hr 39 min 49 sec and oscillation lasted about three minutes The disturbance was less than that produced by the earthquake in Jersey on July 30, 1926

THE Royal Institute of Public Health will hold its annual congress at Portsmouth on June 4–9 The scientific work of the Congress will be conducted in five sections dealing respectively with State medicine and municipal hygiene, health in the naval, military, and air services (including tropical diseases), industrial hygiene, women and children and public health, and tuberculosis

BY kind permission of the president and council of the Royal College of Surgeons of England, the human skeletal material collected by the East African Archæological Expedition during the season 1926–27 and 1928–29, will be on view to the public in the Museum of the Royal College of Surgeons, Lincoln's Inn Fields, for one week from Monday next, Jan 20, during the hours 10 5, and on Saturday, 10 1 A type series of the associated stone implements will also be exhibited

THE annual report and statement of accounts for the year 1928–29 of Livingstone College, Leyton, have reached us The College provides instruction in the elements of medicine for those engaged in work in the mission field During the year, 83 students attended the various courses of instruction The College has paid its working expenses during the year and also reduced the deficit of £933 by £117, but additional donations and subscriptions are required to extend the work

THE Rockefeller Foundation, New York, has issued the fifteenth series of "Methods and Problems of Medical Education" This contains a description of the departments and courses of instruction of the Albany Medical College of the Union University and of the Albany Hospital, Albany, New York, with numerous plans and illustrations It is of interest that Dr Sautter, the professor of contagious diseases, expresses the opinion that the cubicle system of treating infectious diseases is satisfactory only if fully trained nurses are employed, and while cheaper than the ward system, the latter, from the humanitarian view point, has great advantages

THE annual report of the South African Institute for Medical Research contains an account of the routine and research work carried out in the Institute during 1929 Trials made of a bacteriophage active against the plague bacillus as a prophylactic or a therapeutic agent have been unsuccessful Dr Pirrie has found that the plague bacillus is dissociable into two variants, corresponding to the normal or 'S' forms and the 'R' forms of other micro organisms Tuberculosis of South African natives appears to be caused by the human type of tubercle bacillus, as 100 strains of the bacillus isolated were all of this type, and bovine sources of infection play little part, therefore, in the causation of tuberculosis among South African natives

THE Medical Research Council has issued a report entitled "Medical Uses of Radium Summary of Reports from Research Centres for 1928 (*Special Rep Series*, No 144 London H M Stationery Office, price 1*s* net) This has been compiled by the Radiology Committee of the Council, which allocated the radium salt entrusted to it by H M Government to various institutions named As in previous years, the reports are grouped under the headings of regions of the body It may be stated in general that the results so far obtained indicate that while the use of radium as an agent for the treatment of localised cancer has considerable chance of success, once the disease has become generalised the use of radium is mainly palliative The Committee emphasises the fact that

radium therapy is a highly specialised type of work to be undertaken only by properly trained persons

A NOTICE appeared in NATURE of Dec 21, 1929, p 944, of "A Challenge to Neurasthenia", by Miss D M Armitage The price given, namely 5s net, is incorrect, the booklet is available at 2s 6d, or 1s in paper covers

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A lecture assistant in the department of chemistry of the University College of Swansea—The Registrar, University College, Swansea (Jan 20) A mathematical master at the Royal Naval College, Dartmouth—The Head master, Royal Naval College Dartmouth (Jan 20) A science master at the Huddersfield College, for Physics and Chemistry—The Director of Education, Education Offices, Peel Street, Huddersfield (Jan 22) A secretary and director of education under the Wigan Education Committee—The Town Clerk and Clerk to the Local Education Authority, Municipal Offices, Library Street Wigan (Jan 22) An engineering assistant at the Building Research Station of the Department of Scientific and Industrial Research, for work in connexion with investigations on Structural Steelwork—The Director, Building Research Station, Garston, Watford, Herts (Jan 23) A lecturer in physiology at St Thomas's Hospital Medical School —The Dean of the Medical School, St Thomas's Hospital, S E 1 (Feb 14) A professor of electrical engineering at King's College, London—The Academic Registrar, University of London, S W 7 (Feb 21) A senior research assistant at the National Institute of Poultry Husbandry—The Director, National Institute of Poultry Husbandry, Newport, Shropshire Civilian education officers in the Royal Air Force Educational Service—The Secretary, Air Ministry, Gwydyr House, Whitehall, S W 1 A full time lecturer at the Portsmouth Municipal College, for the Training of Wireless Operators for the Postmaster General's certificate—The Secretary, Municipal College, Portsmouth A resident research fellow at Lady Margaret Hall, Oxford—The Hall Secretary, Lady Margaret Hall, Oxford A part time laboratory assistant in the department of hygiene and bacteriology of King's College of Household and Social Science—The Secretary, King's College of Household and Social Science, Campden Hill Road, W 8 A laboratory assistant in the physics department of the Cancer Hospital—The Secretary, The Cancer Hospital, Fulham Road, S W 3

Our Astronomical Column

Rotation of the Galaxy—A *Daily Science News Bulletin* of Jan 1, issued by Science Service, Washington, D C, gives a summary of a lecture given by Dr J S Plaskett at Des Moines, Iowa during the meeting of the American Association for the Advancement of Science It had been found by several observers that the stars of *B* type show on the average an outward motion from our system of about 5 km /sec Dr Plaskett showed that this could be explained in large measure by combining the effect of galactic rotation with the fact that a special group of *B* stars in Scorpio and Centaurus show an unusually high speed for stars of this type He gives 9 km /sec as the mean speed of the more luminous *B* stars, and 12 km /sec for the less luminous ones

It may be noted that Dr Plaskett has just been awarded the Gold Medal of the Royal Astronomical Society for his brilliant researches in stellar spectroscopy

Comet Schwassmann-Wachmann (1)—*Beob Zirk*, No 44, contains an interesting note by Dr W Baade of Bergedorf Observatory on this comet It will be remembered that its perihelion passage occurred in May 1925, more than four and a half years ago On Nov 6 last, Dr Baade failed to photograph it, and concludes that it must have been fainter than mag 17 But on Dec 2 its magnitude had risen to 13 5, and it presented the appearance of a planetary nebula some 18″ in diameter It was again photographed on Dec 5, when its nucleus was of mag 14 3, eccentrically placed in a faint nebulosity The sudden change of brightness recalls the remarkable outburst of Holmes's comet in November 1892, repeated on a smaller scale some two months later D'Arrest's comet in 1923 also exhibited an unexpected increase of brightness from mag 14 to mag 11, although the calculated brightness was diminishing But the change in the present case is still more mysterious, owing to the great distance of the comet from the sun It is now not very far inside the orbit of Saturn, where the solar exciting effect must be very weak It would appear that there is some unknown source of energy in the comets themselves to explain these sudden outbursts

Orientation of the Planes of Binary Stars—There have been many attempts to find whether there is any law governing the orientation of the planes of revolution of the binary stars The conclusions have been curiously inconsistent, some observers finding a concentration of the poles of the planes in the plane of the galaxy, others in the pole of the galaxy, others in positions related to the ecliptic or the solar apex Such discordance is not surprising when we note that when the orbits of binaries are determined simply from measures of position angle and distance, there are two possible positions of the orbit plane, one nearer to us on the north side, the other nearer on the south The investigators tried to avoid the difficulty in different manners, but Mr Y C Chang notes in *Astr Jour*, No 932, that it can only be eliminated in the case of those binaries for which radial velocities have been obtained with the spectroscope over a sufficient arc of the orbit He was able to collect the necessary observations for twelve binaries, and has added four more from results obtained at the Yerkes and Lick observatories The resulting poles are deduced and plotted on two diagrams, referred respectively to the terrestrial equator and to the galactic plane Neither diagram shows any evidence of concentration The distribution appears to be a random one

Mr Chang draws the conclusion that the evidence favours the fission theory of generation of double stars, rather than those of stellar appulse, or adjacent nuclei in a primitive nebula These would be likely to show grouping related either to the direction of the streams of stellar motion, or to the plane of the galaxy

Research Items.

Archæology of the San Joaquin Valley, California —A further study of the archæology of the San Joaquin Valley, in this case covering the northern section, has been published by the University of California in the *Publications relating to American Archæology and Ethnology*, Vol 26, No 4 The authors, W E Schenck and Elmer J Dawson, have examined a number of mounds in this section as well as specimens obtained by other collectors, especially the late Mr H H Barr The mounds, the evidence indicates, were not used exclusively for burial, though these occur throughout the strata and in some cases in the substratum Although some of the human bones were scorched, this was probably due to the burial fire, and cremation was not practised Artefacts were burned at the grave Of those associated with the skeletal remains, which were found in large numbers, pipes, pestles, and obsidian blades were sometimes broken or 'killed' Shell ornaments and beads were the objects most frequently found Though pottery was extremely rare, the large number of objects of clay was one of the unique features of the site Baked clay balls were found in profusion These were probably a local invention, as they are not known elsewhere Their use is obscure Their number is perhaps due to the lack of stone in the area, and they may have been used for some such purpose as fire-stones The age of the mounds in some instances may be put at 1800 A D, as is shown by Caucasian objects associated with the finds, but the oldest mound is calculated to be probably not more than fifteen hundred years earlier

Effects of Environment on Twins —Many studies are now being made of identical twins It is well known that such twins show great similarity not only in appearance but also in such details as finger and palm prints The *American Weekly* of Dec 29 last describes recent studies by Prof H H Newman, of the rare cases in which identical twins have been separated in early life, and have grown up in different environments A pair of twin girls born in London were separated at the age of 18 months, one (Olive) growing up in a poor part of Chelsea and the other in an Ontario town under better conditions They differ in height by only an eight of an inch, but Olive weighed nearly ten pounds more than her sister when the latter joined her in Canada Among numerous other similarities they have the same dental peculiarities Mental tests showed marked superiority of the Canadian girl, partly accounted for by her superior schooling and better health in childhood, but her head is also slightly larger Another pair of identical twins grew up, one in Chicago and the other in a small town in Illinois These young men showed the usual marked resemblances The city boy was better educated and held his facial muscles differently, which made him better looking, but both showed the same intelligence That a tendency to criminality is inherited appears to be shown by observations of Prof Lange in Germany He examined the brothers of 428 criminals Where the twin of a convict was of the ordinary fraternal type, he turned out to be criminal only once in 16 pairs, which is about the ratio for ordinary brothers But in 10 out of 13 cases of identical twins both were criminals, and the three exceptions each had an explanation

Micro-Organisms in Candies and Chocolate —A microbiological investigation of these articles has been undertaken at the Institute of Hygiene, Masaryk University, Czechoslovakia (K Drml, *Publications de la Faculté de Médecine*, Brno, Tchécoslovaquie, 1929, T 7, p 45) It is found that humidity and desiccation are the factors which respectively tend to conserve and to destroy the viability of bacteria upon the surface of confectionery It follows, therefore, that the number of bacteria on confectionery kept in sealed glass or tin-plate containers, and also on chocolates wrapped in tin foil, remains stationary for long periods On the other hand, the packing of confectionery in transparent paper or cellulose bags does not hinder the sterilising influence of desiccation and sunlight while affording sufficient protection from contamination after packing It was found that in samples artificially infected, the typhoid and paratyphoid organisms may remain alive for 2 5 weeks, particularly in chocolates packed in tin foil The need for eliminating all chance of infection during manufacture is emphasised, and transparent or translucent cellulose containers are considered to be the best for packing

Fresh-Water Mollusca of Wisconsin —Two substantial volumes, comprising 1000 pages in all, are devoted to the enumeration and description of the fresh-water Mollusca of Wisconsin by F C Baker (*Wisconsin Geol and Nat Hist Survey Bull*, 70), published under the auspices of the Wisconsin Academy of Sciences, Arts, and Letters The contents of many collections, public and private, were studied and special expeditions were made to different parts of the State by the author, but nevertheless there are some districts yet unexplored that might possibly yield additional species Altogether 327 species and varieties are recognised in this monograph, of which 40 are considered new This is a considerable fauna, as may be realised when it is recollected that the British Isles, with double the area, can only show a hundred aquatic species, or, if allowance be made for those trifling varieties so dear to some collector's hearts, a total of some two hundred forms The descriptive text is full, and copious notes are given as to distribution, ecology, etc, while the nomenclature is on the latest approved American pattern The plates, which number 105, are half tone figures from photographs, and quite satisfactory save in the case of those of the smaller species of bivalves There are plentiful and good text figures illustrating anatomical and other details Each volume has its index, while to the whole work is appended a very full bibliography and a glossary, some of the definitions in which, after the manner of such productions, are distinctly quaint

The California Jack Smelt —Mr Francis N Clark describes the life history of the California jack smelt, *Atherinopsis californiensis*, in Contribution No 77 from the California State Fisheries Laboratory (January 1929, *Fish Bulletin*, No 16 Division of Fish and Game of California) He begins by describing the commercial catch statistics (this being one of the minor fisheries of the State) and fishing gear, then proceeds to length measurements, scale studies, and ova measurements, spawning, age, and rate of growth The fish apparently spawn more than once during a spawning season, which occurs from October to March, and individuals are spawning at all times during the breeding season The largest fish was 33 4 cm in length and was probably nine or ten years old Very few attain 30 cm, and the fish are mature at 18-20 cm at about the end of the second year

Pendulum Observations at Sea —In a recent publication ("Theory and Practice of Pendulum Observations at Sea" J Waltman, Jr, Delft), Dr Vening Meinesz describes the later modifications made by

him in the construction at de Bilt of a new recording apparatus to be used for the determination of gravity at sea Meinesz's method, which reduces the time required to compute an observation from several days to a few hours, was first introduced in 1923, and after his first voyage the apparatus was modified It was tested again in 1925 on a voyage to Port Said, and during the spring of 1926 a further improvement was made by suspending the apparatus in gimbals, and it is hoped that the final results of the voyage to Java during the latter part of that year will be published shortly An additional modification has since been introduced, and the improved recording apparatus in its present form is described in the present publication

Latitude Variations in India —As the result of an inquiry from Prof Wegener, the values of astronomical latitudes of stations in India at which observations have been taken several times at considerable intervals were recently scrutinised to see if they gave any evidence of the crustal movements suggested in the Wegener hypothesis The results are published in the *Geodetic Report*, vol 3, 1926–27, of the Survey of India Observations at fourteen stations were examined At some of these the earliest records were more than a century ago Variations range between −1 56″ and +0 90″ Five sets of observations at four stations cover intervals of less than a year, and nevertheless show changes only slightly smaller than other sets covering a much longer period Of the other ten stations, several appear to show increases of latitude between 1800 and 1870, and others show increases only between 1870 and 1927 The figures from two adjacent stations are directly contradictory The only conclusions that can be derived from these data is that the apparent changes are due to errors in observations and that they afford no evidence of continental drift On the other hand, it is pointed out that the figures do not furnish disproof of a drift of the order of fifty feet a century

New Type of Epidiascope —The increased use of visual methods in education has been accompanied by progressive improvements in the design and construction of optical projection apparatus, and the modern epidiascope, which is compact and easy to manipulate, is rapidly superseding the projection lantern A new type of epidiascope embodying several further improvements has recently been put on the market by Messrs W Edwards and Co The apparatus is constructed on the 'unit' principle The episcope is the basic unit and is so designed that the addition of other units, either as permanent attachments or for temporary use, enables the apparatus to be used for vertical projection, for optical bench work, and for the projection of lantern slides, microscopic slides, or kinematograph pictures The reflecting mirror for episcopic projection is placed inside the apparatus and is thus protected from dust, and the possibility of accidental damage is diminished Illumination is provided by means of a 500 watt standard projection lamp If greater intensity is required a second lamp can be easily introduced The instrument is fitted with anastigmat projection lenses and good definition is obtained over the whole picture Demonstrations of the apparatus can be arranged at any time on application being made to Messrs W Edwards and Co, 8A Allendale Road, London, S E 5

Enumeration of Coincidences —A neat method for counting coincident discharges in two Geiger' α-particle counters is described by Dr W Bothe in the first number of the current volume of the *Zeitschrift für Physik* A four electrode thermionic tube is set up with its two grids connected one to each of the Geiger counters The potential impulses set up by the entry of ionising particles into the counters are thus transmitted to the grids, and the latter have in addition a steady negative potential applied to them of sufficient magnitude to prevent the passage of current through the valve to the anode unless the potentials of *both* grids have been momentarily raised In other words, current pulses are recorded in the anode circuit only when the two counters respond simultaneously to the ionising agency Dr Bothe gives some figures to show the very considerable extent to which the labour inherent in the older direct method for detecting coincidences has been reduced by this device, which appears to have an immediate important application in the investigation of the cosmic radiation

Lead Arsenate Sprays —In recent years lead arsenate solutions have been extensively used as insecticide sprays, and a leaflet issued by the U S Department of Agriculture describes experiments by H S Swingle on the effects of such sprays It was found that, at low concentrations of equivalent arsenic content, arsenious and arsenic acids are equally toxic to peach foliage At higher concentrations arsenic acid is the more toxic Arsenic acts as a cumulative poison within peach leaves The minimum concentration of arsenic acid toxic to peach foliage contains the equivalent of 0 0012 per cent of arsenic pentoxide Acid lead arsenates containing less than 0 25 per cent of arsenic pentoxide in water-soluble form gave minimum foliage injury Nothing of practical importance is gained by further reduction in soluble arsenic Lead arsenate cannot be used upon susceptible plants without the addition of some material to prevent burning

Proteins in Brewing —A melancholy interest is attached to a paper recently published in the *Journal of the Institute of Brewing* (35, 532, 1929) under the name of the late Prof S B Schryver Not only was it intended to serve as an introduction to a series of his researches under the auspices of the Institute of Brewing research scheme on the proteins and their relation to the industry of brewing, but also it was dictated from the sick bed and read by proxy, and the discussion was never seen by the author even in manuscript After a discussion of the nature and constitution of the proteins, it is shown that investigation of the large number of unknown factors which determine the rôle of nitrogen in brewing falls under three heads (1) The variations in nitrogen in barley due to differences in soil, climate, and other conditions, (2) the changes produced in barley proteins during malting, (3) the variations in the nitrogenous constituents of wort and their utilisation by the growing yeast In connexion with the third problem, great importance is attached to the fact, originally established by Horace Brown twenty years ago, that a relatively large proportion of the protein matter in wort cannot be utilised by the yeast When in fact these proteins occur in the colloidal state, they may even inhibit growth by settling out with the yeast and choking it As a result of such researches, it may be possible in the future to choose the barley and regulate the malting process so as to reduce these detrimental colloids to a minimum, or alternatively, the colloidal matter may be partly or wholly removed from the wort or prevented from precipitating during fermentation It will be seen that Prof Schryver has provided his successors with a tempting field of possibilities, and it may confidently be anticipated that the seeds he has sown will produce a rich harvest

The Twentieth Annual Exhibition of the Physical Society and the Optical Society.

THE exhibitions of electrical, optical, and other scientific apparatus arranged by the Physical and Optical Societies have grown steadily in interest and importance year by year, and that held on Jan 7, 8, and 9 last was decidedly the most successful of all The exhibition was housed, as usual, in the Imperial College of Science, and although additional accommodation was allotted, the available space was filled to compression with extremely interesting exhibits

An important new section has been introduced, with the object of encouraging craftsmanship in the scientific instrument trade Prizes were offered to apprentices and learners for the best examples of craftsmanship and for the best designs, drawings, or tracings All too little has been done in the past to encourage young instrument makers to take a pride in their art, and it was gratifying to see the high standard attained As the competition was the first of its kind, readers of NATURE may be interested to know the results in detail They were as follows Class *A*, Craftsmanship senior grade (18 21 years) (1) J H Richards (Creed and Co, Ltd), perforator punch block, (2) P D Betteridge (Griffin and Tatlock, Ltd), voltmeter movement, and A Mead (Adam Hilger, Ltd), micrometer eyepiece, honourable mention S W Angel (Negretti and Zambra), Bourdon tube and spindle, and W G Sibley (H Tinsley and Co), six dial resistance box Junior grade (under 18 years) (1) E G Sawyer (Negretti and Zambra), geared movement of quadrant form, (2) R H Brockman (Adam Hilger, Ltd), proof plane of quartz Class *B*, Draughtsmanship senior grade (1) H Downing (General Electric Co, Ltd), (2) E G Baker (George Kent, Ltd) and E Lowings (George Kent, Ltd), honourable mention, A G Haslam (H W Sullivan, Ltd) Junior grade (1) S W Holdstock (George Kent, Ltd), (2) E F Woods (George Kent, Ltd) Scientific progress depends directly on the skill of the instrument maker, and the stimulus provided by a competition of this kind should therefore prove decidedly beneficial

The number of exhibits in the remaining sections was so great that it is out of the question to do justice to them in a short article A full account of the most interesting will be found in the catalogue, which has been printed in a form suitable for binding up with the proceedings of the participating societies Here it is possible only to mention briefly a few items which happened to attract the attention of the writer, and a different observer might well have made a different selection

The section devoted to research and experiment, another feature which has recently been added to the exhibition, is expanding in a satisfactory manner Group *A* comprised nearly a hundred exhibits illustrating recent research Those contributed by the National Physical Laboratory included a wireless oscillator for wave lengths down to 1 5 metres and a direction-finder for wave lengths of 4 10 metres, a 0 00002 ohm standard resistance for direct current up to 20,000 amperes, consisting of 40 parallel water cooled manganin tubes joining two copper discs, to the peripheries of which a number of cables are symmetrically connected in parallel, the arrangement being designed to avoid errors arising from variation of current distribution in the end connexions, and a demonstration of the use of the hot wire anemometer for detecting turbulent flow In the latter a hot wire, in circuit with an amplifier feeding a loud speaker, is situated close to the surface of a stream lined body in a blast of air Normally the loud speaker is silent, but disturbance of the flow by the interposition of a pencil or the like produces loud sounds Messrs R W Paul and B S Cohen showed a series of loud speaker diaphragms made of balsa wood, an extremely light and stiff material the response curves actually measured are found to correspond closely with curves predicted on the assumption that the diaphragms are rigid

In a Kundt's tube excited by a valve driven diaphragm, demonstrated by Prof E N da C Andrade and Mr S K Lewer, the dust particles are found to form sharp and accurately measurable rings at the antinodes, the amplitude of vibration of individual particles can be observed directly (the particles being seen as short lines parallel to the axis of the tube), and the tube is sealed to preserve the purity of the gas (see NATURE, Nov 9, 1929, p 724) A solution has been provided by the British Thomson Houston Co, Ltd, of a problem which must have racked the brains of many youthful electricians, namely, the transformation at high efficiency of direct current supply For this purpose a mercury vapour rectifier having an oxide coated hot filament as cathode and a magnetic control is used This rectifier has several interesting properties and will probably be put to many uses For the purpose of direct current transformation, it is made to commutate the low tension supply, and the resulting alternating voltage, after being stepped up by an ordinary transformer, is rectified to yield a high tension direct current output

A curious experiment on weak suspensions of clay was contributed by the Rothamsted Experimental Station When the solid matter forms a few per cent of the whole, the suspension behaves as a liquid for ordinary stresses, but as an elastic solid for very small shearing stresses, the critical value of the stress increasing rapidly with concentration A viscometer of the rotating cylinder type was demonstrated, the outer cylinder, which contains the clay, being suspended, while the inner revolves For very slow speeds of rotation the torque increases regularly with speed, but when the shearing stress exceeds the critical value a very large increase in the speed makes little difference to the torque The Research Laboratories of the Gramophone Co, Ltd (H M V), and the Marconiphone Co, Ltd, also demonstrated a magnetically controlled mercury vapour relay, and another interesting feature of their stand was a cathode ray oscillograph arranged to show, on a time base, the dying away of a sound picked up by a microphone in the hall, the sound supply being cut off suddenly after a steady distribution of sound intensity had been attained Messrs C E Wynn Williams and Ward showed apparatus for counting the passage of α particles based on the usual principles, but having the unusual feature that the impulses initiated by the passage of the particles are applied to a mechanical counter, the number-cylinders of which are seen to move step by step as the particles emerge

A good deal of ingenuity can be exercised in the devising of lecture experiments and teaching apparatus of an inexpensive type, and this year the section of the exhibition devoted to such matters was very well supported A very fine collection of improvised apparatus was shown by Mr F A Meier, of Rugby, the most striking being, perhaps, that in which a diffraction pattern is formed by means of three steel balls in contact Talbot's bands were produced by Mr A C G Beach (Chelsea Polytechnic) by placing between a spectrometer and an observing telescope an additional slit having half its width occupied by

a strip of celluloid film Paper clips of the 'bull dog' type have often featured in apparatus constructed by hard pressed teachers under the stress of enforced economy, but the usefulness of these fac total objects has been much extended by Mr D G A Dyson by the addition of brass terminals, which facilitate attachment to the steel rods that figure in improvisations of the kind in question Mr J E Calthrop, of East London College, has devised a simple hydrometer for measuring surface tension, it consists of a glass vessel made of two cylinders of different diameters having their axes in line The vessel is loaded with mercury so that it floats vertically with either end uppermost, and the volumes which stand above the surface of the liquid in the two positions differ by an amount which gives the surface tension in absolute units

In the trade section the largest share of attention was attracted by those firms—happily a large and increasing number—which enter into the spirit of the exhibition and contrive to make their stalls scientifically interesting There is still a certain number of firms who are content to set up a kind of shop window full of unedifying boxes with terminals or eyepieces on their outsides, but the more enterprising exhibitors contrived to provide excellent demonstrations or dis assembled instruments and even they were far too numerous for individual mention The Cambridge Instrument Co, Ltd, had, as usual a very fine display of new apparatus Among the instruments which attracted our attention was a seismograph for detecting salt domes and for locating geological faults, it was noteworthy for a delicate and effective application of the toggle principle for multiplying movement The same firm showed a recording colorimeter in which light, after passing through solution the colour density of which varies with time, affects a photo electric cell which controls a thread recorder The current supply is drawn from the mains and ripple is eliminated by an ingenious device, the filament of a triode valve is heated with alternating current, and the anode is supplied through a resistance with rectified current from the same source, fluctuations in the mains vary both the valve impedance and the potential drop in the resistance in such a way that the effects of these variations cancel one another The Ashdown rotoscope, manufactured by Elliott Bros (London), Ltd, for observing objects in periodic motion and measuring their periodicity, is a stroboscope with a useful feature for rendering the view of the object instantaneous, while permitting good apparent illumination the shutters consist of rotating sets of parallel laminæ, so that a good instantaneous view is afforded when the laminæ are horizontal, but a very sharp cut off is effected as soon as the laminæ have rotated through a small angle Among Messrs Hilger's exhibits was a system for spectrographic analysis by Barratt's method Two spark gaps, one having electrodes of known composition, while the other has electrodes of the substance under test, are connected in series so as to take the same current, and the relative intensities of the same spectral line when derived from each of the two gaps are found by means of a photometer of the polarisation type

The M O Valve Co, Ltd, set an excellent example by installing an automatic grid making machine, which was seen in action Nothing is more interesting to visitors than a glimpse of manufacturing processes such as the one thus afforded It is, however, impossible to do more than pick out, more or less at random a few plums from the embarrassingly rich fare provided

Discourses were delivered as follows on Jan 7, Lord Rayleigh on "Iridescent Colours in Nature from the Standpoint of Physical Optics", on Jan 8, Mr S G Brown on "Gyro Compasses for Gun Fire Control", and on Jan 9, when the general public was admitted free, Sir Ambrose Fleming on "Television, Present and Future"

Prize Awards of the Paris Academy of Sciences

AT the annual public meeting of the Paris Academy of Sciences, held on Dec 16, the prize awards for the year were announced as follows

Mathematics —The Francœur prize to Paul Noaillon, for his researches in mathematical analysis and hydrodynamics

Mechanics —The Poncelet prize to Alfred Liénard, for his works on the application of the general theories of mechanics to the problems of electrostatics, electrodynamics, and magnetism, the Henry Bazin prize to Charles Camichel, for his experimental study of eddies in liquids with the aid of metallic particles in suspension

Astronomy —The Lalande prize to Alexandre Véronnet, for the whole of his astronomical work concerning the figure and constitution of the heavenly bodies, the Damoiseau prize to Gaston Fayet, for his memoir on the eccentricities of cometary orbits, the Valz prize to Louis Dunoyer, for his researches on spirit levels and photoelectric cells

Geography —The Gay prize to Ludovic Gaurier, for his work on the lakes of the Pyrenees, the Tchihatchef foundation to Paul Pollacchi, for his French colonial atlas

Navigation —Prize of the Ministry of Marine to (the late) Eugène Émery, for the whole of his work, the Plumey prize to Pierre Clerget, for his improvements in motors for air navigation

Physics —The Gaston Planté prize to Charles Féry, for his work on the theory of the lead accumulator, the Hébert prize to Georges Déjardin, for his researches on ionisation potentials and on the classification of spectral lines of various atoms, the Henri de Parville prize to Marcel Pauthenier, for his work on Kerr's electro optical phenomenon, the Hughes prize to Jean Jacques Trillat, for his researches on molecular orientation made by means of the X rays, the Clément Félix foundation to René de Mallemann, for his work on rotatory polarisation

Chemistry The Montyon prize (unhealthy trades) to Daniel Florentin, for his work on the hygiene of large towns, the Jecker prize between Richard Fosse, for his work in agricultural, biological, and organic chemistry, and Marcel Sommelet, for the whole of his work in organic chemistry, the Cahours foundation between Henri Moureu, for his researches on the tautomerism of the α diketones, and Raymond Quélet, for his work on certain derivatives of benzene, the Houzeau prize to André Travers, for his work in inorganic and analytical chemistry

Mineralogy and Geology —The Delesse prize to Marius Dalloni, for his geological work on northern Spain and Algeria, the Fontannes prize to Alfred Carpentier, for his work on palæobotany, the Victor Raulin prize to Pierre Bonnet, for his geological work on Armenia

Botany —The Desmazières prize to Hubert Bourdot, for his work on the Hymenomycetes of France, the Montagne prize between Pierre Dangeard (1000 francs), for his memoir on *Bangia* and *Porphyra*, and Robert Potier de la Varde (500 francs), for his work in bryology, the Thore prize to Charles Douin, for his work on the

structure of the Muscineæ, the de Coincy prize to Paul Dop, for the whole of his botanical work

Anatomy and Zoology —The Cuvier prize to Émile Topsent, for the whole of his work, the Savigny foundation to Henri Gauthier, for his researches on the fauna of the continental waters of Algiers and Tunis

Medicine and Surgery —Montyon prizes to Gaston Cotte (2500 francs), David and Jean Olmer (2500 francs), Francis Rathery (2500 francs), Honourable mentions (1500 francs) to Charles Joyeux, Camille Simonin, and Mlle Suzanne Guéry, the Barbier prize to Prosper Merklen and Maurice Wolf, for their work on the anatomy and pathology of the reticulo endothelial system, the Bréant prize between Marcel Léger (3000 francs), for the whole of his work relating to plague, and Pierre Lereboullet and Georges Boulanger Pilet (2000 francs), for their clinical and therapeutical manual of diphtheria, the Godard prize to François Aman Jean, for his memoir on the thoracic lumbar region, the Mège prize to René Monceaux, for his memoir on disturbances of the nutritive exchanges in pulmonary tuberculosis, the Bellion prize to Paul Chavigny, the Barron Larrey prize to Joseph Uzac, for his memoir on the medico surgical organisation in the army, the Argut prize to Robert Leroux-Robert, for his memoir on high frequency in oto rhino laryngology

Physiology —The Montyon prize to André Strohl, for his work on the electrical conductivity of the human body, the Pourat prize (in equal parts) between Léon Velluz, for his memoir on the biochemical properties of the ethylene linkings, and Henri Bulliard and Antoine Giroud, for the whole of their work on the epidermis, the Philipeaux prize to Louis Genevois, for work in plant biology, the Fanny Emden prize to César Baudi de Vesme, for the whole of his work on the history of experimental spiritualism

Statistics —The Montyon prize to Maurice Olivier, for a work on the index numbers of the variation of prices

History and Philosophy of the Sciences —The Binoux prize to Prosper Jules Charbonnier, for his work on the history of ballistics, the Henri de Parville prize to Jean Paul Bounhiol, for his work entitled "La Vie"

Medals —The Berthelot medal to Daniel Florentin, Mlle Germaine Marchal, André Travers, the Henri Poincaré medal to Louis de Broglie, for his work on wave mechanics

General Prizes —The prize founded by the State (Grand prize of the physical sciences) to René Dubrisay, for the whole of his work in physical chemistry, the Bordin prize to Henri Bénard, for his work on vortices, the Lallemand prize to Mlle Marie Louise Verrier, for her memoir on the eyes and vision of fishes, the Serres prize to Pol Bouin and Paul Ancel, for their work on the mechanism of the differentiation of secondary sexual characters, the Petit d'Ormoy prize (mathematical sciences) to Paul Montel, for the whole of his work on the theory of functions, the Petit d'Ormoy prize (natural sciences) to Paul Gaubert, for the whole of his mineralogical work, the Jean Jacques Berger prize to (the late) Émile Gérard, for his geological map of the twenty *arrondissements* of Paris, the Saintour prize to Bertrand Gambier, for the whole of his work in infinitesimal geometry, the Lonchampt prize to Pierre Lesage, for his researches on the action of sea salt on the development of plants, the Wilde prize to Léon Brillouin, for his work in physics, the Gustave Roux prize to André Roussel, for his work in mathematical analysis, the Thorlet prize to Adolphe Richard

Special Foundations —The Lannelongue foundation between Mmes Cusco and Rück, the Helbronner-Fould prize to Mme Louis Gentil

Prizes of the Grande École —The Laplace prize to Maurice Borgeaud, the L E Rivot prize between Maurice Borgeaud, Alfred Flinois, Paul Moch, and Édouard Beltrémieux

Foundations for Scientific Research —The Trémont foundation to Charles Frémont, for his work in applied mechanics, the Gegner foundation to Paul Gautier, for his work in connexion with the Lecoq Museum at Clermont Ferrand, the Hirn foundation to M Janvier, for his researches on the Hymenoptera of Chile

The Loutreuil Foundation

Out of 27 applications for assistance from this fund, grants were made in the following 21 cases

(1) *Researches on Specified Subjects* —2000 francs to François Maignon, for the continuation of his researches on the mechanism of venous sclerosis, of anaphylaxy, the rôle of fats in the utilisation of proteins, the influence of the seasons and of the genital glands on basal metabolism, 3000 francs to Gabriel Marotel, for undertaking researches on Douve's disease and its treatment, 2000 francs to Robert Hamy, for the study of the conditions determining the curdling of milk, 2000 francs to Henri Colin, for the purchase of apparatus for micro analysis for use in his researches on the carbohydrates, 5000 francs to Henri Cottier, for research into inheritance in crosses of Asiatic and French cattle, 2500 francs to Claude Gautier, for his researches on the evolution of the total albumenoids of the liver under the influence of nutrition by casein peptone, or by a complex mixture of amino acids, 7000 francs to Edmond Roy Prémorant, for the construction of his diasthypsometer, a geodesic instrument

(2) *The Purchase of Material for Researches* —5000 francs to Émile Demoussy, for the reorganisation of the laboratory of agricultural chemistry at the national agronomic institute, 5000 francs to René Dubrisay, for the laboratory of general chemistry at the Conservatoire national des Arts et Métiers, 10,000 francs to the Museum of Histology of the Hôpital de Saint Louis for the purchase of projection apparatus, 25,000 francs to the Observatory of Ksara, for the purchase of a seismograph, 10,000 francs to the Colony of Tahiti, and 10,000 francs to the Colony of New Caledonia, as a contribution to the creation of a seismological station in each of these islands

(3) *The Purchase of Books* —3500 francs to the National Veterinary School of Toulouse, for completing its French and foreign collection of scientific books and periodicals, 4000 francs to the library of the National Agronomic Institute for the same object, 8000 francs to the library of the École supérieure d'électricité, for the purchase of Wien's treatise on physics (35 volumes), 5000 francs to the society for the encouragement of national industry, for its library

(4) *Voyages and Explorations* —5000 francs to Paul Pallary as a contribution to the cost of a zoological expedition in Syria, 3000 francs to Dr Vellard, to assist his researches in pure and medical zoology in the less known parts of Brazil

(5) *Publications* —5000 francs to the Faune des colonies françaises, 3000 francs to Gaston Fayet, for the publication of the *Bulletin de l'Observatoire de Nice*

The total grants made amount to 128,000 francs

The Victor Noury foundation between Victor Delahaye (3000 francs), for a book on the physical geography of Indo China, V Babet (2000 francs), for his work on the geology of Mayombé, and Mlle Germaine Marchal, for the whole of her work, the Charles Bouchard foundation to Serge Oberlin, for his work (with Dr R Grégoire) on anatomy, the Le Chatelier foundation to Mlle Jeanne Foret, for her researches in inorganic chemistry, the Roy-Vaucouloux foundation to Eugène Wollman, for his work on life under aseptic conditions

Annual Meeting of the Mathematical Association

"GENERAL impressions", said Sir Francis Galton, "are never to be trusted" This general impression (which, if trusted, convicts itself of untrustworthiness) was effectively quoted by Mr B L Gimson in opening the discussion on "Arithmetic of Citizenship" at the annual meeting of the Mathematical Association on Jan 6 and 7 Though later in the meeting 'general tendencies' or 'laws out of focus' were put forward as governing human life, and therefore to be brought within the mathematician's domain through the study of probability and correlation, yet it may be granted that the mathematician above all others should be dissatisfied with general impressions where quantitative data are available Mr Gimson outlined a course of civic arithmetic classified by human interest instead of by arithmetical processes, under such headings as 'Local Finance', 'National Finance', 'Saving, Banking, and Investment', 'Insurance', etc His experiments, carried on for five or six years with classes of boys and girls of the type commonly called unmathematical, have proved that these children can successfully and with keen interest work upon such real life data as are to be dug from "Whitaker's Almanack" or the prospectuses of insurance companies

Those who were inclined to suspect Spherical Harmonic Functions of being excessively abstract found their suspicions agreeably dissipated by Prof S Chapman's lecture on their application to mathematical physics Among the interesting concrete examples which he gave was that of the magnetic field of the earth, expressible as the sum of two convergent series, one of negative powers of the distance from the centre of the earth, giving the part of the field due to extra terrestrial causes, the other of positive powers, giving the part originating from within Work begun in 1600 by Gilbert, and carried on later by Gauss, led to the conclusion that this internal part predominates, but it is only by the use of spherical harmonic functions that 94 per cent of the field is now attributed to an internal origin, 3 per cent to causes residing in the lower air, and 3 per cent to the influence of the sun and other bodies outside the earth In striking contrast to this is the distribution of the responsibility for the diurnal magnetic variation, about 5/7 of which is directly dictated from outside the earth, while the 2/7 which analysis assigns to the inside is probably due, if traced another step towards its source, to internal currents induced by those passing outside A further deduction from this analysis of the earth's magnetic field is that the earth's electrical conductivity, after changing but little within 200 miles of the surface, increases considerably below that depth

The principle of a certain celebrated pump was (rather loosely perhaps) described to an inquirer in these words "You leave out the piston, and compensate for its absence by leaving out the rest of the pump But it works" This also appears to be the principle on which 'The Dalton Plan' works You leave out the class room, the lesson, the chalk, and the teacher without these hindrances the pupil learns as naturally and inevitably as water flows uphill Without (or even with) the proved fact that it sometimes does work, one would call it impossible Mr G W Spriggs, opening the discussion on "Problems of Individual Education, with special reference to Mathematics", gave a most illuminating and well thought out account of his own experiments at the Tiffin Boys' Secondary School, first on the Dalton Plan itself, and later on various modifications of it which his own experience suggested Men of science would feel a certain glow of self satisfaction if they were not above such human weakness, at the news that his principal success has been in sweeping away the atmosphere of the mathematical classroom and substituting for it the spirit of the chemical or physical laboratory, where groups collaborate and discuss instead of sitting chained to desks and books Many will agree that the education of the future may with advantage develop in this direction as economics may towards communism if there is value in the analogy it lies in the lesson that communism, though ideal when it appears as a natural growth, is the most disastrous of failures when imposed by authority

Prof W M Roberts, of the Royal Military Academy, Woolwich began his lecture on "Gunnery and some of its Mathematical Problems" by some quotations from Tartaglia's 'Colloquies", written in 1546 To this Tartaglia is due the solution of the cubic equation for which the charlatan astrologer Cardan appropriated the credit clearly a conspicuously able mathematician, of an intellectual calibre fit to win distinction in any age Nothing brings home to us so startlingly the extent of our debt to Galileo and Newton as the pitiable dynamics of this master mind groping in the darkness of the Aristotelian world Two guns are placed, equidistant from a given wall, one at the level of the foot of the wall, the other as high as its top Both fire so as to hit the top of the wall which hits it harder? "The higher", says the Duke, a practical man, who, like Dr Watson or a Greek chorus, serves as a foil for the sage's wisdom "No," says Tartaglia

The science of weight saveth contrary The pellot weigheth less obliquely and therefore flyeth more heavily out of a piece that lyeth level than when it lyeth crooked" Another consideration is that the pellot which started from the lower and more elevated piece would go farther before hitting the ground, if the wall were removed, than would its rival from the higher and less elevated therefore it contains more force "You have argued well", said the Duke

In 'the cupping effect' Tartaglia is on surer ground The rapid cooling of the hot gas after firing causes a low pressure in the barrel, which in "The Bombardier's Story" whuffled an excessively inquisitive dog into the muzzle, where he served as an unwilling piston "If one shall stick his bare belly against the muzzle, he shall not without great difficulty leave the spot" Members of the Mathematical Association have only themselves to blame if they try this experiment after Tartaglia's and Prof Roberts's warning

Gunnery would have been better in the War if officers, or even if only instructors had understood the theory underlying the practice of the 'long bracket' and 'short bracket' and their connexion with the '50 per cent zone' On the assumption that four times the 50 per cent zone constitutes a 100 per cent zone containing every shell fired at a given elevation, Prof Roberts explained the problem, "Given an observer who can only see whether the shell falls beyond the target or short of it, how to bring the Mean Point of Impact as near as possible to the target in the minimum number of rounds" The answer is well known and is taught to gunners as rule of-thumb the reason for the answer deserves more attention than it had when most of our artillery officers had never seen Woolwich

Dr W F Sheppard in his presidential address dealt with "Mathematics for Study of Frequency Statistics" The future, I believe, will criticise the mathematicians of our time more for their backward

ness in making this subject a part of every mathematician's education than for any of our other defects If the next generation is less open to this criticism than ours, their thanks will be due to a small body of workers among whom Dr Sheppard is a notable figure On this occasion he touched only lightly on frequency distribution, giving his chief attention to interpolation What percentage of those who use, and possibly think they can prove, the binomial theorem know that it arose originally from Newton's researches into interpolation? Yet probably an even smaller percentage can attempt for themselves anything beyond 'straight line' or 'first difference' interpolation Dr Sheppard's paper showed this simple process as a first approximation to various series employed by Newton, Gregory, Euler, Maclaurin, Whittaker, and others, with special emphasis on those 'central difference' formulæ which avoid the unsymmetrical tendency to take more account of observations on one side of the required point than on the other

The final discussion on "The Mathematician in Ordinary Intercourse", after being ably opened by Miss Hilda P Hudson in a speech somewhat critical of her own calling, degenerated into a (fortunately finite) series of addresses on the subject 'Are we remarkably fine fellows?' On this question there was conspicuous unanimity W HOPE JONES

Annual Conference of the Geographical Association

THE annual conference of the Geographical Association was held at the London School of Economics on Jan 2-4, and was attended by between 400 and 500 delegates and members from all parts of Great Britain The publishers' exhibition included an unusually fine display of wall maps and other maps for teaching purposes The outstanding feature of this year's conference was the series of lectures by prominent business and professional men, all of them indicating very clearly the position which geography occupies as a key subject in a liberal education and in a preparation for a variety of careers

Sir Henry Lyons, before handing over the office of president to Mr B B Dickinson (who founded the association thirty seven years ago), dealt in his address with co operation between the geographer and surveyor The surveyor is concerned with the application of accurate physical methods to the measurement of the earth however much the geographer may use the results, surveying is not a branch of geography But the interpretation of the surveyor's results, and especially the selection of matter to be incorporated in maps on a reduced scale, calls for accurate geographical knowledge Col Cochran Patrick, of the Aircraft Operating Company, lectured on air survey, and emphasised the fact that aerial photographs record far more than can be incorporated on a topographical map Many contracts for air survey now stipulate that a finished vertical photograph shall be supplied side by side with the finished map of the same area The use made by archæologists of aerial photographs is well known, and it is interesting to record that the Aircraft Operating Company now employs a forest officer with a long experience in the tropics to assist in the interpretation of forested country Sir John Russell, in his lecture on agricultural developments in South Africa, also stressed the importance of such co operation

REGIONAL SURVEY

No less than three meetings were devoted to different aspects of regional survey work, and of outstanding importance was the discussion on the land utilisation map of Northamptonshire Under the guidance of Mr E E Field, and with the support of Mr J L Holland and the Northamptonshire Education Committee, the whole of Northamptonshire, comprising more than 300 parishes, was surveyed by village school children On the six inch maps of the Ordnance Survey was marked the utilisation of each field—whether arable, grass, woodland, or waste—and the maps so obtained were reduced to the one inch scale and the results published in three sheets by the Ordnance Survey Provided the necessary funds can be obtained, the Geographical Association, following up the success of this pioneer work, proposes to establish a land utilisation survey of Britain, with a central office in London, which shall act as an organising and collecting centre for work of a similar character The support of the Ordnance Survey, of various education authorities, and of agricultural authorities has been promised, and inquiries should be addressed to Dr L D Stamp at the London School of Economics

THE ACTUARY AND THE GEOGRAPHER

Under the title of "The Mortality of Europeans in Equatorial Africa A Study of the Effects of Improved Conditions and Mode of Life", an important paper was read by Mr H E Raynes For life insurance purposes an accurate estimate of probable mortality under tropical conditions is obviously of the greatest importance The most trustworthy figures available relate to government servants, of all ranks and drawn from all classes, employed in West Africa In the period 1881-1897 the death-rates per 1000 per annum were 75 8 for the Gold Coast and 53 6 for Lagos Since that time the improvement has been simply amazing—a consistently rapid decline, interrupted only during the years of the War and immediately after, when many officials were overworked and their leave long overdue The improvement has been specially marked since 1921, and at all ages the death rates in 1925-28 were an improvement on those for 1921-24 In the period 1925-28 the rate varied from 6 5 per 1000 at the age of 25 to 12 1 per 1000 at age 45, dropping to 9 3 for age 50 and over A similar reduction in the 'invaliding rate'—Europeans sent home on sick leave or retired as unfit—is also seen It is often asserted that the resident from the tropics returns home ruined in health and doomed to an early death Records of retired officials from West Africa, however, show in 1926-28 a mortality of 14 6 per 1000 per annum, against the normal for Great Britain of 15

Under modern conditions the European in the tropics has an expectation of life differing almost imperceptibly from that in his native country Deaths are not due to the climate—the 'poisonous atmosphere' of the tropics is a myth—but to lack of precaution against disease Nearly all tropical diseases are preventable, because they are either water borne or insect borne There are three essential factors in modern conditions—segregation (because of opportunities of social intercourse amongst Europeans and a resulting high moral standard), sanitation, and personal hygiene Good, even luxurious, housing and good food are necessities, not luxuries, for the European in the tropics The comparatively high mortality amongst missionaries emphasises the result of a lower standard of comfort

BRITISH NATIONAL PARKS

Dr Vaughan Cornish entered an eloquent plea for a national coastal park, and for reasons of winter climatic conditions, emphasised the suitability of parts of Pembrokeshire or Cornwall

THE NORWICH FOLK MUSEUM

At the conclusion of the London meeting, a party of members visited Norwich at the invitation of the Norwich branch On the Saturday evening they were received by the Lord Mayor (Councillor H Harper Smith), who, in a lantern lecture, outlined the growth of the city, and gave the Association some idea of the wisely planned and actively pursued efforts of the Corporation to preserve the ancient monuments in which Norwich is so rich and to develop the amenities of the city in all directions The reception was held in the Strangers' Hall, a beautiful medieval mansion presented to the city by the late Mr L G Bolingbroke and since utilised for the housing of the first 'Folk Museum' in the country Of parallel interest is the Bridewell Museum, another medieval mansion, and a magnificent example of squared flint work, which houses a collection illustrating local industries There are few cities which can boast a comparable collection so well arranged, and it is hoped that its immense educational value will be maintained by keeping the exhibits up to date as Norwich industries develop

On Sunday the party studied the agriculture of Norfolk between Norwich and Cromer, and the coast erosion and geology between Cromer and Sheringham Monday was devoted to a morning tour of the city, and an afternoon visit to Messrs Colman's mustard works

L DUDLEY STAMP

Annual Meeting of the Science Masters' Association

THE full programme of the thirtieth annual meeting of the Science Masters' Association under the presidency of Prof J C Philip, held at the Imperial College of Science, with evening meetings at King's College for Women, appeared in NATURE of Dec 28 in the Diary of Societies

Twelve years ago the membership of the Association was about 200 and the whole exhibition of traders, publishers, and members was confined to one large room in the London Day Training College To-day the membership is 1560, about 500 of whom attended the recent four days conference The members' exhibit alone, consisting of about 70 pieces of apparatus made in school workshops, much of it original and very ingenious, occupied the whole of the large Physical Chemistry Laboratory of the Imperial College, whilst the traders' and publishers' exhibition was most extensive and instructive, occupying two laboratories, one being the largest in the building This remarkable development of the Association is of course due to the original founders having the vision to throw open the membership to all male teachers of science in secondary schools The friendly contact and fellowship between men with varying types of teaching experience is probably one cause of the particularly bright and stimulating discussions which were an outstanding feature of this year's conference, and show that teachers of science as a body are keenly alive and that school science is in a healthy condition This does not mean that teachers of science are satisfied either with the content of their courses or the methods of teaching They realise that school science is a relatively recent development and as such is of necessity still in the experimental stage—a fact apt to be overlooked by the critics

Many of the members feel, with the president, that after the school certificate stage the tendency has been to make the courses for science specialists too intensive On the other hand, others prefer to keep within the narrower limits on the ground of thoroughness There is room for both types of post matriculation course according to the natural abilities of the pupils and the qualifications of the teacher

The need for closer co operation between university and school is keenly felt by science masters, and during the recent conference the rector of the Imperial College, the president of the Association, and the four professors who initiated the discussion on "Openings for College Trained Men in the Mineral Industry", all made special reference to this

For years science masters have been much exercised in their minds about the value of practical examinations at the school certificate stage Some examining bodies demand them others do not and it is not surprising that science masters are also divided on the question But a general feeling prevails that some form of practical examination is desirable at the school certificate stage This should test the ability to do *practical* work and not *theoretical* work or *mathematics* The joint discussion with the Physical Society on "Examinations in Practical Physics" was noteworthy, in that a new method of examining practical work was put forward by Dr L F Richardson and Mr R S Maxwell, who call it the 'pantopiric' method In it a large number of simple experiments are to be done in, say three hours, the candidates moving round like the members of a family coach every time a bell is rung Mr Meier, of Rugby School, mentioned that he had tried this with a class, setting six short experiments to be done in two hours and he was convinced that this method, combined with a practical examination in which all the candidates answered one and the same question in three hours, gives a trustworthy method of testing practical work

The discussion on broadcasting which followed the specimen lesson on "Liquids", given by Mr A F Walden and broadcast by the B B C from an adjacent temporary studio, elicited the fact that there is a great divergence of opinion on the value of broadcast lessons in science It was agreed that broadcasting might be utilised to bring boys and girls into touch with recent developments by enabling them to listen to accounts broadcast by the actual discoverers A resolution was passed that "This Association suggests that broadcasting is not a suitable medium for the science lesson, but recognises that it might be of use in presenting lectures on general science subjects at a time outside the ordinary school time table"

The past neglect of the teaching of biology in the schools has been partly owing to the fact that physics and chemistry developed earlier and that these subjects lend themselves more readily to laboratory treatment, partly also to the fact that biology should be first of all an outdoor study, and this raises time table difficulties seldom appreciated by headmasters The well attended discussion on "School Certificate Biology", at which the syllabus printed in last week's NATURE was discussed, directed attention to the fact that teachers of the subject work under very varying conditions in regard to time allowance, laboratory accommodation and assistance, money available, etc, making common agreement on a syllabus difficult This could be overcome by schools sending their own

syllabuses for approval by the examiners Resolutions were passed that papers on biology should not include questions in pure chemistry and physics, that there should be no separate practical examination, that in many schools definite field work is at present impossible, that biology should be a subject which ranks for matriculating purposes on the same footing as other subjects, and that the course should be primarily for general education purposes

The retiring chairman, Mr W J Gale, handled the meetings with his usual skill In previous years he has rendered the Association excellent service, first as a member of the committee and later as secretary The chairman for 1930 is Mr F Fairbrother, of the Cedars School, Leighton Buzzard, and the new president is Sir Charles Grant Robertson, principal of the University of Birmingham, where the next meeting is to be held

University and Educational Intelligence

BRISTOL —Dr R J Brocklehurst has been appointed to the chair of physiology Dr Brocklehurst took first class Hons Schools at Oxford, and was assistant in physiology, at first part time, then whole time, at St Bartholomew's Medical College in 1925–26 He was awarded a Radcliffe Travelling Fellowship from Oxford, with which he went to America and Germany from 1926 until 1928, returning to take up a post as senior lecturer at University College, London, in August 1928 His new appointment dates from Aug 1 next

LEEDS —Plans have now been approved for the new building to accommodate the Department of Chemistry—Inorganic, Organic, and Physical This building, stretching, when completed, from the Physics Department to Woodhouse Lane, will, together with the mining block at right angles to it, form the north elevation of the new scheme The east elevation will run alongside Woodhouse Lane, for a distance of about 180 feet, and at its lower end another wing, containing a number of large laboratories, will reach back a distance of 240 feet towards the physics building and will form the southern side of the rectangle of which the complete building will consist The erection of certain portions of the chemistry block is being postponed, but even so the building shortly to be started will have a floor space of some 95,000 square feet

THE Board of Governors of the Hebrew University in Jerusalem has authorised the various science departments and institutes to conduct formal courses in biological sciences The establishment of a School of Tropical Medicine has also been approved The School is to be in connexion with the proposed medical centre in Jerusalem, which is being planned jointly with the American Jewish Physicians' Committee and the Hadassah Medical Organisation Dr S Adler has been promoted to be professor of parasitology and director of the Department of Parasitology at the University, and he has been granted twelve months' leave in order to carry out investigations on kala azar for the Royal Society Dr A Fraenkel, formerly professor of mathematics at the University of Kiel, has been appointed professor of mathematics in the Einstein Institute of Mathematics at the University, and Dr M Felete has been made associate professor of mathematics A special course in advanced bacteriology for graduate students is being given by the Department of Hygiene

Historic Natural Events.

Jan 20, 1607 Severn Floods —Stow records that "the waters rose above the tops of the houses", and the event is commemorated by a painted board in the church at Kingston Seymour The flood came suddenly, many persons were drowned and much cattle and goods lost, the water in the church was five feet high and lay on the ground about ten days The floods extended along the coast for about 20 miles and reached a depth of 12 feet in places The East Anglian fens were widely flooded by the same storm, and in Romney Marsh the sea came in so "outrageously" that it did not seem as if the area could ever be reclaimed

Jan 20, 1838 Great Cold —On Jan 7 a very severe frost set in and continued a month Jan 20 is described as the coldest day of the century in London, temperature fell to $-4°$ F at Greenwich, $-13\frac{1}{2}°$ F at Beckenham, and $-14°$ F at Walton near Claremont

Jan 21–22, 1904 Hurricane in Fiji —A violent hurricane struck the eastern part of the Fiji Islands, probably coming from north of east, recurving near the group and passing away to the south east Many houses and coco nut trees were destroyed, and the lowlands were flooded six feet above high tide mark

Jan 22–24, 1879 Glazed Frost —At Fontainebleau and Orleans rain fell steadily for three days at a uniform temperature of 27° F, freezing as it fell A layer of ice an inch thick formed on the ground, while the branches and twigs of the trees and the telegraph wires were covered by shells of ice of the same or greater thickness

Jan 23, 1556 Great Earthquake —The Chinese earthquake of this date, the most destructive in human life of all known earthquakes, was especially severe in the provinces of Shensi and Shansi In some places, houses and parts of cities sank into the earth More than 830,000 persons were killed

Jan 23, 1855 Great Earthquake —The earthquake that occurred on Jan 23 in 1855 was one of the strongest of New Zealand earthquakes, having disturbed an area of about 360,000 sq miles The earthquake is remarkable for the wide spread changes of elevation that accompanied it A tract of land in the southern portion of the North Island, about 4600 sq miles in area, was raised from 1 to 9 feet, the greater amount being reached along an old fault for a distance of 90 miles along the foot of the Remutaka Mountains In the South Island, the ground was usually depressed from 1 to 5 feet, though over a smaller area

Jan 23, 1895 Thunderstorm and Squall —Shortly before 10 A M, intense darkness and thick fog came on suddenly in London, followed abruptly by a sharp thunderstorm with a heavy shower of hail, while temperature dropped 5° F and the wind rose suddenly from nearly calm almost to gale force The storm was traced across England from Leeds to Sussex, at Bramley near Guildford there was heavy snow and great destruction of trees The thunderstorm was followed by a severe frost

Jan 24, 1666 Wind Storm —Pepys records that "It was dangerous to walk in the street [of London], the bricks and tiles falling from the houses that the whole streets were covered with them, and whole chimneys, nay, whole houses in two or three places, blowed down But, above all, the pales on London Bridge on both sides were blown away, so that we were fain to stoop very low for fear of blowing off the bridge We could see no boats in the Thames afloat,

but what were broke loose, and carried through the bridge, it being ebbing water And the greatest sight of all was, among other parcels of ships driven here and there in clusters together, one was quite overset and lay with her masts all along in the water, and keel above water "

Jan 24, 1684 Great Frost—Under this date Evelyn wrote "The frost continuing more and more severe, the Thames before London was still planted with boothes in formal streetes, all sorts of trades and shops furnished and full of commodities even to a printing presse Coaches plied from Westminster to the Temple, and from several other staires, to and fro as in the streetes, sleds, sliding with skeetes, a bull baiting, horse and coach races, puppet plays, and interludes, cookes, tipling, and other lewd places, so that it seemed to be a bacchanalian triumph, or carnival on the water" This frost continued from the beginning of December to Feb 5, and according to Maitland's 'History of London' a whole ox was roasted on the ice near Whitehall On the Mendip Hills the snow was more than six feet deep in places and people were buried, some of it still remained at midsummer This was the winter described in "Lorna Doone"

Jan 24, 1926 The Largest Sunspot—On this day the largest sunspot seen in recent years (certainly since 1874 when the Greenwich photographic series was instituted) passed across the sun's central meridian The spot, complex in structure, was about 70,000 miles in length and occupied an area of nearly 4000 millions of square miles This region of the sun was active in the preceding December, when a large spot, only slightly inferior to the great spot of January, was also easily seen with the naked eye On Jan 25 and again on Feb 22 when the spot had diminished, brilliant gaseous eruptions were observed spectroscopically The region was marked throughout by a great extent of bright faculæ which persisted for more than six months A magnetic storm, presumably related to this active solar region, took place on Jan 26-27, and was followed one synodic solar rotation later by another on Feb 23 25

Jan 25, 1757 Damage by Lightning—Above 20 feet of the upper part of the spire of Lostwithiel Church, Cornwall, were thrown down and dispersed in all directions, and some pieces were found at the distance of 200 yards The vane was thrown down and bruised, its socket being rent open "as if it had been burst by gunpowder, and in such a manner as could not well be occasioned by the fall"

Societies and Academies

LONDON

Royal Meteorological Society, Dec 18—**J Edmund Clark and I D Margary** Floral isophenes and isakairs It is now possible to compare the annual isophene map with the average map and to prepare from it a map showing for that year the variations from the average in all parts of the British Isles Lines are drawn through points of equal variation defining areas of real earliness or lateness and are called 'isakairs' (equal unseasonableness) Maps so prepared are more instructive than the original isophene maps, for these are based on the original observations, which are always dependent on altitude, latitude, etc, in addition to the changing weather factors In the isakair maps these constant influences are removed and the relation of weather to plant growth can thus be more readily followed Isakair maps have been prepared for every year from 1891 They show the general distribution and degree of earliness and lateness in the first eight months of each year, and form a unique series for such information —**Sir Gilbert T Walker** On the mechanism of tornadoes The prevailing idea that the area of a tornado is roughly vertical has been opposed by Wegener, who maintained that it is horizontal In this paper it is urged that while Wegener's evidence against a vertical axis is conclusive, he does not provide an adequate explanation of a horizontal direction, and that the rotation of the earth will, when convergence occurs, set up a spin parallel to its axis This view is supported by the almost universal anti clockwise rotation of tornadoes in the northern hemisphere and, in general, by the photographic evidence —**E W Bliss** A study of rainfall in the West Indies The rainfall in the eastern islands of the West Indies is related to the circulation of the North Atlantic during the months March to May preceding, and is deficient when the circulation is more vigorous than usual, there is a close relationship with temperature in the Cape Verde Islands, and low temperatures tend to be followed by deficient rainfall In addition, the rainfall in this part of the West Indies belongs to the first group of the southern oscillation

Linnean Society, Dec 19—**Dame Helen Gwynne-Vaughan and Mrs H S Williamson** A contribution to the study of nutritive heterothallism In *Humaria granulata* a coprophilous member of the Discomycetes, nutritive heterothallism is associated with the presence of a functional oogonium The spores are incapable of germination until five months after they are shed, they remain viable for a year or more Single spore cultures produce normal archicarps, but these fail to form ascogenous hyphæ In about 50 per cent of cases fruits develop where two monothallic strains meet The strains are of two kinds, + and − Since each produces oogonia, the difference between them cannot be sexual Mycelial fusions are common, when they take place between + and strains, the oogonia in the neighbourhood form ascogenous hyphæ and develop into fruits Their asci contain both + and − spores, showing that fusion of + and nuclei takes place **F Howard Lancum** On the eviction method of the cuckoo Photographs of the process were secured last summer illustrating the various stages The average time taken by young cuckoos to effect an eviction is three and a half minutes In the case photographed although the cuckoo ejected the egg many times during the morning, in only one instance did it take longer than twenty seconds to do so The photographs showed that the cuckoo insinuated a wing underneath the egg and tilted it inward on to its hollowed back where it was held by the bird s wings and backward tilted head The egg is then pushed up the wall of the nest, the cuckoo meanwhile turning its back to it and maintaining a firm grip on the nest material with its feet, The throwing out movement commences by the cuckoo pushing the egg out backwards with its outspread wings, and finishes with a very vigorous push This cuckoo evicted the same egg (which was replaced on each occasion) fifteen times in an hour The strength and persistence of so young a bird (approximately thirty six hours old), which could repeatedly evict an egg nearly as heavy as itself, climbing an almost perpendicular wall to do so, were remarkable

PARIS

Academy of Sciences, Dec 9—**Gabriel Bertrand and L Silberstein** The relative importance of sulphur and phosphorus in the nutrition of plants It has been proved in earlier communications that determinations of sulphur and phosphorus in the ash of plants

is liable to give erroneous figures for the proportions of these two elements present in the plant, owing to variable losses on ignition Analyses avoiding this source of error are therefore given In estimating the sulphur requirements of a soil, regard must be had to the fact that considerable proportions of it may be masked by the presence of barium Sulphur must be considered as an element to be taken into account in the manurial treatment of the soil —**E Mathias** Contribution to the study of fulminating matter Globular lightning forming holes in the ground —**A Demoulin** The theory of networks —**H Krebs** The deformation of surfaces —**Mandelbrojt and Gergen** Functions defined by a series of Dirichlet —**D S de Lavaud** The variations of sensibility of self tightening brakes on motor vehicles —**H Mineur** The Keplerian movement disturbed by a field of external gravitation —**P L Mercanton** The true height of the Beerenberg of Jan Mayen The values obtained for the height of this mountain by different observers show large variations Barometric observations in 1921 gave 2276 metres direct measurement with a base line of 1062 metres gave 2274 metres Hence the map due to the Austrian expedition of 1882-83 requires correction in this and in other distances found in error —**A Gruvel** A fishery map of a part of the western coast of Morocco —**T Takéuchi** Machines which work between two radiant sources —**A Zmaczynski and A Bonhoure** The boiling point of water as a function of the pressure A development of the apparatus devised by W Swietoslawski for measuring the boiling points of water under different pressures The two electrical resistances employed were standardised over the range 0° 200° C at the Bureau International des Poids et Mésures Over the pressure range 683 832 mm of mercury, the results found were intermediate between the results of Holborn and Henning and of Chappuis, the concordance with the observations of the latter being close —**A Guillet** The use of a galena detector in measurements worked with a variable current —**Stefan Vencov** The hydrogen spectra obtained by electronic shock in a mixture of hydrogen and mercury vapour —**Adolfo T Williams** Spectral terms and chemical valency —**R Lucas and Mlle D Biquard** The influence of temperature and of solvents on the rotatory powers of active substances Data for the rotatory power of *l* fenchone, *d* cyanocamphor, *d* anisylcamphor, and dimethylmalic ester at various temperatures and also in different solvents In these cases it is not possible to account for the variations of the specific rotatory power by the hypothesis of the existence of only two active forms —**Georges Fournier and Marcel Guillot** The radiation responsible for the raising of the absorption curves relative to radium $(D+E)$ —**F Bourion and E Rouyer** Boiling point study of the molecular equilibrium of resorcinol in solutions of calcium chloride —**M Bourguel and Mlle V Gredy** The mechanism of catalytic hydrogenation —**H Pélabon** The action of iodine vapour on phosphorus vapour The volatility product —**E Herzog and G Chaudron** The alteration of the mechanical properties of sheets of duralumin after corrosion by sea water The pinholes produced in the duralumin by attack by sea water reduce the elongation, but do not sensibly reduce the breaking load —**André Job and Georges Champetier** The fixation of acetylene by phenylmagnesium bromide in the presence of ferric chloride —**G Dedebant** Mathematical contribution to the analysis of the field of pressure —**C Dauzère** The formation of electrical charges in storms A discussion of Simpson's theory of rain, with special reference to the cause of the positive electrical charge —**A and G Hamel** The heterogamy of *Lola lubrica* (Cladophoraceæ) —**Paul Dop** Two new genera of Bignoniaceæ of Tonkin —**N Wagner** The evolution of the chondriome in the seeds of *Phaseolus multiflorus* —**Jean Mercier** Observations on the *Psammechinus miliaris* of the bay of the Seine —**Mme Y Khouvine, E Aubel, and L Chevillard** The transformation of pyruvic acid into lactic acid in the liver

SYDNEY

Linnean Society of New South Wales, Nov 27 —**F H S Roberts** A revision of the Australian Bombyliidæ (Diptera) (Pt 3) This paper deals with the lesser subfamilies —**R Broom** On some recent new light on the origin of the mammals Additional light is thrown on the problem by a recently discovered specimen from Ladybrand, Orange Free State, from the Cave Sandstone, of Rhaetic or Lower Jurassic age The new animal is a small mammal like creature about the size of a rat, but with relatively large head and a long tail Together with *Karoomys, Pachygenelus* and *Tritheledon*, it is placed in the new sub order —**W F Blakely** A further contribution to our knowledge of the flora of New South Wales This paper deals with the description of six new species of plants, one of each of the following genera *Correa* (Rutaceæ), *Bertya* (Euphorbiaceæ), *Lasiopetalum* (Sterculiaceæ), *Kunzea* (Myrtaceæ), *Prostanthera* (Labiatæ) and *Goodenia* (Goodeniaceæ) —**W L Waterhouse** Australian rust studies (Pt 1) Teleutospore germinations of *Puccinia graminis tritici* E and H occur over a more extended period than had been previously determined The æcidial stage has been produced repeatedly, but on no occasion by *P graminis tritici* 43 Protound alterations in the reactions produced in seedlings by forms of *P graminis tritici* and other rusts may be brought about by altering the environmental conditions in the plant house In Australasia there have been found seven naturally occurring physiological forms of wheat stem rust, and five of oat stem rust, together with two forms of *P triticina* Certain grasses have been shown to be important hosts of cereal rusts Evidence has been obtained pointing clearly to the fact that rusts over summer in the uredospore stage on 'volunteer' cereals as well as on grasses —**A L Tonnoir** Australian Mycetophilidæ Synopsis of the genera A review of the Australian Mycetophilid fauna to date A list of the genera is given, ten being described as new and the total recorded for the different States being brought to forty seven A peculiar adaptation of the palpi as prehensile organs in one species is described, as well as a case of mimetic resemblance of a Mycetophilid to a Hymenopteron

WASHINGTON, D C

National Academy of Sciences (*Proc*, Vol 10, No 10, Oct 15) —**P W Bridgman** (1) On the application of thermodynamics to the thermo electric circuit By a rearrangement of the argument, the equations of Kelvin for this circuit can be deduced rigorously from thermodynamics without assuming the justifiability of neglecting the effect of necessary irreversible processes —(2) On the nature of the transverse thermo magnetic effect and the transverse thermo electric effect in crystals There is a fundamental difference in sign in the relations connecting the Ettingshausen with the Nernst coefficient and their crystal analogues —**F Zwicky** On the red shift of spectral lines through interstellar space A qualitative, theoretical discussion of a new effect of masses upon light which is a sort of gravitational analogue of the Crompton effect It offers an explanation of the high receding velocities of very distant nebulæ —**E L Hill** Relative inten

sities in nuclear spin multiplets A theoretical discussion —M S Vallarta On Einstein's unified field equations and the Schwarzschild solution —Charles E St John Elements in the sun Of the 92 possible elements, 90 have been found in the earth and 58 in the sun's atmosphere There are many faint lines and several strong ones in the solar spectrum as yet unidentified Some of the strong lines are probably due to common elements, and since corresponding lines are not produced in laboratory, their presence suggests exceptional conditions of excitation —Alfred J Lotka Biometric functions in a population growing in accordance with a prescribed law —J L Walsh Boundary values of an analytic function and the Tchebycheff method of approximation N Wiener and M S Vallarta On the spherically symmetrical statical field in Einstein's unified theory a correction

Diary of Societies

FRIDAY, JANUARY 17

LONDON SOCIETY (at Royal Society of Arts) at 5 —F W Parker London's Parks and Open Spaces

ROYAL SOCIETY OF MEDICINE (Balneology Section) at 5 —Dr V Coates Tissue Reaction in Rheumatic Disorders with Particular Reference to Subcutaneous Nodules

BRITISH INSTITUTE OF RADIOLOGY (Medical Members) at 5 —Radiology in Bone and Joint Diseases

SOCIETY OF CHEMICAL INDUSTRY (Liverpool Section) (at Liverpool University) at 6 —Prof E C C Baly The Activated Sludge Process for Sewage Disposal

SOCIETY OF DYERS AND COLOURISTS (Manchester Section) (at Manchester) at 7 —W Kershaw Faults in Textiles

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting) at 7 —T Walley The Pooling of Experience —a Function of the Institution

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group—Informal Meeting) at 7 —P D Johnston Photographic Conventions

ELECTRICAL DEVELOPMENT ASSOCIATION (at Royal Society of Arts) at 7 30 —C H Smith Domestic Hot Water

JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7 30 —G Andrew Marshall London's Water Supply

ROYAL SOCIETY OF MEDICINE (Obstetrics and Gynaecology Section) at 8 —Dame Louise McIlroy and Miss Iris Ward Three Cases of Imperforate Hymen occurring in one Family Dr J H Hannan Zondek Aschheim Tests for Pregnancy —Prof J P Maxwell Further Studies in Osteomalacia.

ROYAL SOCIETY OF MEDICINE (Electro Therapeutics Section) at 8 30 —P Anderson Cutting Currents

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (jointly with Local Section of Institute of Chemistry) (at Thomas Café Swansea) —J F J Dippy The Geochemistry of Coal and the Natural Hydrocarbons

SOCIETY OF DYERS AND COLOURISTS (London Section) —H Clayton Lake Colours—Manufacturer and Users

SOCIETY OF DYERS AND COLOURISTS (Scottish Section) —J G Grundy Colours Suitable for Hosiery and Tweeds

PAPER MAKERS ASSOCIATION (Technical Section—London Division) (at Connaught Rooms Great Queen Street, W C)

PAPER MAKERS ASSOCIATION (Technical Section—Northern Division) (at Engineers Club Manchester).—T T Potts The Permeability of Paper to Air

SATURDAY JANUARY 18

PHYSIOLOGICAL SOCIETY (at King's College) at 3 —Prof J Barcroft and J J Izquierdo The Effect of Temperature on the Pulse Rates of the Frog and Cat respectively —Prof J Barcroft and F Verzar The Effect of Temperature on the Pulse Rate of Man —L E Bayliss and A R Fee A Flow Recorder and Automatic Pump Control —Prof J Mellanby The Isolation of Prothrombase from Mammalian Blood.—Prof R J S McDowall Vagus Restraint as a Rebound Phenomenon —H W Kinnersley and Prof R A Peters Local Lactic Acidosis Accompanying Symptoms of Opisthotonus in the Pigeon —F R Curtis Adrenaline and Related Amines —S Wright Action of Ergotamine on Vasomotor Reflexes —C Heymans and J J Bouckaert Sinus Caroticus and Respiratory Reflexes Cerebral Blood Flow and Respiration, Adrenaline Apnoea —R C Garry Amytal and the Inhibitory Action of the Vagus on the Heart —J A Hewitt Protozoan Parasites in Human Heart Muscle B Sarkar The Use of Iron and Tannic Acid as a Tissue Stain —A D Macdonald and E D McCrea Observations on the Actions of the Nerves to the Bladder —*Demonstrations* —Prof R J S McDowall (*a*) The Use of the Vertebral Clamp (*b*) Central Sympathetic Stimulation (*c*) A Convenient Method of Obtaining a Low Potential Current for Class Purposes (*d*) On the Making of Tambours —Prof R J S McDowall and A Shore The Action of Adrenaline on Perfused Pulmonary Vessels —B Finkleman A Simple Inhibitory Nerve Smooth Muscle Preparation —F R Curtis The Interaction of Adrenaline and Ephedrine —S Wright and H A Bulman Intestine of Cat following X Radiation —M Pratt and E B Wright Quantitative Estimation of Photosynthesis —Elizabeth C Eaves The Fields of Vision for Colours of Normal and Colour blind Students —J A Hewitt Sarcocystis in Cardiac Muscle —B Sarkar

Tissues Stained by Iron and Tannic Acid —F W R Brambell and M Allanson Variation in the Number of Acidophil Cells in the Pars Anterior of the Pituitary of Adult Female Rabbits
NELSON TEXTILE SOCIETY (at Preston Technical School) —C A Harrington Designing of Fancy Fabrics

MONDAY, JANUARY 20

VICTORIA INSTITUTE (at Central Buildings Westminster), at 4 30 —Lt Col L M Davies Scientific Discoveries and their Bearing on the Biblical Account of the Noachian Deluge
ROYAL GEOGRAPHICAL SOCIETY (at Lowther Lodge) at 5 —Lt Col R C F Schomberg Climatic Conditions in the Tarim Basin
INSTITUTION OF ELECTRICAL ENGINEERS (Mersey and North Wales (Liverpool) Centre) (jointly with Liverpool Engineering Society) (at Liverpool University), at 7 —Discussion on Low Temperature Carbonisation of Fuel with Special Reference to its Combination with the Production of Electricity Introductory Papers by E H Smythe and E G Weeks (English Practice), and S McEwen (American Practice)
INSTITUTION OF ELECTRICAL ENGINEERS (South Midland Centre) (at Birmingham University) at 7 —T W Ross and H G Bell Recent Developments in the Protection of Three Phase Transmission Lines and Feeders
INSTITUTION OF MECHANICAL ENGINEERS (Graduates Section London), at 7 —O S Nock Modern Methods of Speeding up Railway Traffic
INSTITUTION OF AUTOMOBILE ENGINEERS (Glasgow Centre) (at Royal Technical College Glasgow) at 7 30 —Dr B P Haigh The Relative Safety of Mild and High Tensile Steels under Alternating and Pulsating Stresses
BRADFORD TEXTILE SOCIETY (at Midland Hotel Bradford) at 7 30 —D R H Williams Costing from a Manufacturer's Point of View
HUDDERSFIELD TEXTILE SOCIETY (at Huddersfield Technical College) at 7 30 —Dr S G Barker Recent Developments in Woollen Yarn Manufacture, including Carding and Spinning
ROYAL SOCIETY OF ARTS, at 8 —H J L Wright Three Master Etchers Rembrandt, Meryon, Whistler (Cantor Lectures) (1)

TUESDAY, JANUARY 21

ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15 —Dr F W Aston Isotopes (1)
ROYAL STATISTICAL SOCIETY (at Royal Society of Arts), at 5 15 —B Ellinger Japanese Competition in the Cotton Trade
SOCIETY OF CHEMICAL INDUSTRY (Birmingham and Midland Section) (at Chamber of Commerce, Birmingham), at 6 30 —E J Dobbs Chrome Plating
LONDON NATURAL HISTORY SOCIETY (at Winchester House, E C), at 6 30 —W G Freeman Trinidad
INSTITUTION OF ELECTRICAL ENGINEERS (East Midland Sub Centre) (at Loughborough College), at 6 45 —L C Grant The Breaking Performance of High Power Switchgear and of a New Form of Quenched Arc Switch
INSTITUTION OF ELECTRICAL ENGINEERS (North Western Centre) (at Engineers Club Manchester), at 7 —B A G Churcher and A J King The Analysis and Measurement of the Noise emitted by Machinery
INSTITUTION OF HEATING AND VENTILATING ENGINEERS (Associate Members and Graduates Section) (at Milton Hall, Manchester) at 7 —R Sutcliffe Air Conditioning for Cotton Mills
ILLUMINATING ENGINEERING SOCIETY (at Royal College of Music, South Kensington), at 7 —C H Ridge The Art of Stage Lighting
MANCHESTER ATHENÆUM TEXTILE SOCIETY (at Manchester Athenæum), at 7 —L G Larmuth Artificial Silk
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN at 7 —Capt G I Finch Mountain Shots in Kodacolor
INSTITUTION OF AUTOMOBILE ENGINEERS (Coventry Graduates Meeting) (at Broadgate Café, Coventry) at 7 15 —L Hathaway Preparation of an Engine for Production
INSTITUTION OF AUTOMOBILE ENGINEERS (at Engineering and Scientific Club, Wolverhampton), at 7 30 —T W Cooper Roller Bearings
INSTITUTION OF ELECTRICAL ENGINEERS (North Midland Centre) (at Albert Hall Leeds) at 7 30 —Capt P P Eckersley Broadcasting by Electric Waves (Faraday Lecture)
SHEFFIELD METALLURGICAL ASSOCIATION (at 198 West Street Sheffield) at 7 30 —G Stanfield Temperature Distribution and Stress Effects in Heating and Cooling of Masses
LEICESTER LITERARY AND PHILOSOPHICAL SOCIETY (Chemistry Section) (at College of Technology Leicester), at 8 —M P Applebey Manufacture of Synthetic Nitrogen
ROYAL INSTITUTE OF BRITISH ARCHITECTS at 8 30 —Presidential Address to Students

WEDNESDAY, JANUARY 22

ROYAL SOCIETY OF MEDICINE (Comparative Medicine and Surgery Sections), at 5 —Discussion on Actinomycosis Common to Man and Animals
GEOLOGICAL SOCIETY OF LONDON at 5 30 —Prof J W Gregory, Dr Ethel Dobbie Currie, Dr J Weir Dr S Williams and Dr G W Tyrrell On the Geological Collection from the South Central Sahara made by Mr Francis Rodd —J V Harrison The Geology of some Salt-Plugs in Laristan (South Persia)
INSTITUTION OF AUTOMOBILE ENGINEERS (Manchester Centre) (at Engineers Club, Manchester) at 7 —H K Whitehorn Petrol Electric Vehicle Characteristics
NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Graduate Section) (at Newcastle upon Tyne), at 7 15 —R Harding The Psychology of the Shipbuilding Industry
ROYAL SOCIETY OF ARTS, at 8 —G Stone Observations on the Mining Laws of the British Empire

THURSDAY, JANUARY 23

ROYAL SOCIETY, at 4 30 —Lord Rayleigh Normal Atmospheric Dispersion as the Cause of the 'Green Flash' at Sunset, with Illustrative Experiments —Dr F W Aston The Photometry of Mass Spectra and the Atomic Weights of Krypton Xenon, and Mercury —Prof O W Richardson A New Connexion between the Absorption Spectrum of Hydrogen and the Many Lined Spectrum —Dr P A M Dirac A Theory of Electrons and Protons —*To be read in title only* —R V Southwell and L Chitty On the Problem of Hydrodynamic Stability I —P J Daniell The Theory of Flame Motion —N K Adam and Dr O Rosenheim The Structure of Surface Films. Part XIII —F C Johansen Flow through Pipe Orifices at Low Reynolds Numbers —W B Pleass Some Physical Conditions Affecting the Setting of Gelatin and the Bearing of the Results on the Theory of Gel Formation —N F Mott The Collision between Two Atoms —C C Tanner and Prof I Masson The Pressure of Gaseous Mixtures III —F J W Roughton The Time Course of the Heat Effects in Rapid Chemical Changes Parts I and II —E T Hanson Diffraction —C E Marshall A New Method of Determining the Distribution Curve of Polydisperse Colloidal Systems Parts I and II —N K Adam Structure of Surface Films XIV —Prof E V Appleton Some Measurements of Equivalent Height of the Atmospheric Ionised Layer —T E Stein Some Remarks on the Conduction of Electricity in Metals and upon Allied Phenomena —A Harvey The Zeeman Effect in the Band Spectrum of Helium II —N F Mott The Wave Mechanics of a Ray Tracks
LINNEAN SOCIETY OF LONDON at 5
ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15 —Prof H A Harris The Growth of Children in Health and Disease (1)
INSTITUTION OF ELECTRICAL ENGINEERS at 6 —L C Grant The Breaking Performance of High Power Switchgear and of a New Form of Quenched Arc Switch
ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts) at 6 30 —H B Howard Certificates of Airworthiness
INSTITUTION OF ELECTRICAL ENGINEERS (Irish Centre—Dublin) (at Trinity College, Dublin), at 7 45 —Lt Col S E Monkhouse and L C Grant The Heating of Buildings Electrically by means of Thermal Storage
ROYAL SOCIETY OF MEDICINE (Urology Section) at 8 30 —A Clifford Morson The Pathology and Treatment of Carcinoma of the Penis
INSTITUTE OF RUBBER TECHNOLOGISTS (at Manchester Café Ltd, Manchester) —B D Porritt Some Aspects of Standardisation
INSTITUTION OF WELDING ENGINEERS (at Birmingham) —C A Hadley Modern Improvements in Resistance Welding Machines
ROYAL AERONAUTICAL SOCIETY (Yeovil Branch) (at Yeovil) —B L Martin Wapiti Steel Wing Construction

FRIDAY, JANUARY 24

PHYSICAL SOCIETY (at Imperial College of Science), at 5 —J M Nuttall and E J Williams A Method of Examining Stereoscopic Photographs —S E Green The Photography of Fabry and Perot Interferometer Fringes by the Use of a Simple Optical System —Miss W A Leyshon Characteristic of Discharge Tubes under 'Flashing' Conditions as Determined by the Use of a Cathode Ray Oscillograph —Demonstration by W E Doran of a pH Apparatus
INSTITUTION OF MECHANICAL ENGINEERS at 6 —E Watson Smyth General Operating Experiences with the first Wood Steam Generator
NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Newcastle upon Tyne) at 6 —R A MacGregor Failure of Steel Forgings and Castings through Fatigue
INSTITUTION OF CHEMICAL ENGINEERS (at Institution of Civil Engineers) at 6 30 —Dr H Levinstein Films and Fibres derived from Cellulose (Lecture)
JUNIOR INSTITUTION OF ENGINEERS, at 7 30 —W J Rees Refractories for Steam raising Furnaces
LEICESTER TEXTILE SOCIETY (at Victoria Hall Leicester) at 7 30 —F Willis Knitted Footwear
TEXTILE INSTITUTE (Lancashire Section) (at Harris Technical Institute, Preston), at 7 30 —J Starkie The Weaving of Artificial Silk
ROYAL SOCIETY OF MEDICINE (Epidemiology Section) at 8 —Dr G P Crowden Industrial Efficiency and Fatigue
ROYAL INSTITUTION OF GREAT BRITAIN, at 9 —Sir William Bragg Cellulose in the Light of the X Rays

SATURDAY, JANUARY 25

ROYAL INSTITUTION OF GREAT BRITAIN, at 3 —Prof R W Chambers Sir Thomas More and His Friends (1)
BRITISH ASSOCIATION OF MANAGERS OF TEXTILE WORKS (at Manchester Athenæum) at 6 30 —F H Smith Foreign Yarn Business

PUBLIC LECTURES

FRIDAY, JANUARY 17

UNIVERSITY COLLEGE, at 5 —G P Wells Comparative Physiology (Succeeding Lectures on Jan 24, 31, Feb 7, 14, 21 28, Mar 7, 14, and 21)

MONDAY, JANUARY 20

UNIVERSITY COLLEGE, at 5 —Prof A V Hill Oxygen and the Recovery Process in Muscle and Nerve (Succeeding Lectures on Jan 27, Feb 3 and 10)

TUESDAY JANUARY 21

KING'S COLLEGE, at 5 —Dr S Wright Physiology of Posture and Movement. (Succeeding Lectures on Jan 28 Feb 4 and 11)—At 5 30 —Dr C H Lobban Bridges and Bridge-Construction (Succeeding Lectures on Jan 28 and Feb 4)
UNIVERSITY COLLEGE at 5 —Prof S. Radhakrishnan An Idealist Philosophy of Life (Hibbert Lectures) (Succeeding Lectures on Jan 22, 28, and 29)—At 8 15 —Miss E Jeffries Davis How London became the Capital of England (Succeeding Lectures on Jan 28, Feb 4, 11, and 18.)

WEDNESDAY, JANUARY 22

UNIVERSITY COLLEGE, at 5 30 —J H Helweg Northern Mythology (Succeeding Lectures on Jan 29 and Feb 5

SATURDAY, JANUARY 25

HORNIMAN MUSEUM (Forest Hill), at 3.30 —H Harcourt Things Old and New from India's Treasury

SATURDAY, JANUARY 25, 1930

Rationalisation

TO be reasonable may seem to the follower of custom to involve a disturbing rashness; and to be scientific may seem to imply an unnecessary exactness where 'hit or miss' has been the method used. Thus in Great Britain rationalisation may appear to be either revolutionary or too meticulous, although it is only the inevitable result of the advance in industrial methods which has occurred during the past twenty years. Words have a mythological power. In Germany 'pure reason' is admired; and the Germans seem to have invented the non-psychological industrial use of the word 'rationalisation'. In the United States, because there men revere 'science'—with little understanding of it—the phrase first used for the new policy was 'scientific management'. In general, as Mr. Urwick shows in his book, "The Meaning of Rationalisation," this name for an industrial policy implies the application of the exact methods of science to the organising of production. In its primitive form this policy involved only Taylor's plan for studying the movement of workers in machine production, for the purpose of eliminating unnecessary effort; but now the policy of rationalisation involves also (1) scientific research on materials, machinery, and sale methods, and (2) scientific or exact replanning of the managerial and financial organisation of an enterprise, leading in many cases to amalgamation of enterprises.

As an example of the need for reorganisation after a period of unorganised growth, mention may be made of a particular enterprise which has greatly expanded in the past twenty years. On investigation, the managing director of the firm in question found that his office was sending about 300 orders for stationery during the year to about 30 different firms. The incidental waste of energy and money affected the cost of production; but the system was the result of 'accretion' without design. Still more costly waste occurs in the iron and steel processes which some firms have inherited; and in methods of distribution the waste incidental to changes in the places where people live and changes in their habits are obvious in our streets. Of the need for thinking and for replanning traditional methods there is no doubt: the only common doubt appears to be how far we should carry our thinking.

Scientific research is clearly desirable, for the days of chance discovery of material or processes are probably over. But research on an adequate scale is too costly for small enterprises, and therefore

research is one of the reasons for more inclusive organisations The results of research on dyes have been discussed by Mr James Morton in his recent paper, read before the Royal Society of Arts, on "Fast Dyeing and Dyes" The Department of Scientific and Industrial Research provides some of the needs which are more generally supplied in Germany and the United States by large industrial organisations, independent of the State

Again, it is generally agreed that new machinery or new processes will reduce the cost of production, and rationalisation may therefore increase productivity, with less effort on the part of the worker and lower 'overhead charges' even when the new machinery is expensive In the Clyde engineering and shipbuilding trades, the same production as in 1914 can now be obtained with only about 60 per cent of the labour There was an indication of the new situation when an engine was placed in a ship in one afternoon, which it would have taken three weeks and perhaps six times the number of men to place in a ship in 1914 Similarly, in the United States "automatic electro-pneumatic systems of freight car control have eliminated switchmen Seven men used to operate trains in the New York subways now with automatic controls one motorman and one guard compose the crew The Boston and Maine railroad has a freight handling mechanism to take care of a million freight cars a year Switchmen and brakemen are eliminated One skilled man in a tower directs the process It saves the labour of four hundred workers" Such is the descriptive example given in Mr Stuart Chase's "Men and Machines"

From one point of view this process looks like an elimination of waste or of unnecessary effort and thus it is connected with the elimination of unremunerative plant, which, as the *Times* City notes on Dec 17 expressed it, has "become obsolete through the rapid march of science" The same notes continue "the bankers must bear some share of the responsibility for the slowness with which the principles of rationalisation have been practised"—they continue to give financial facilities to obsolete processes How many balance-sheets include values for assets that are really worthless? Thus rationalisation comes to mean 'facing facts' and eliminating waste plant and deleting mythical 'capital', as well as dismissing unnecessary labour

It is here that a new aspect of rationalisation appears, which is being studied by the International Industrial Relations Association, which exists for the promotion of satisfactory human relations in industry Passing beyond the old 'scientific management' into what is now known as 'industrial psychology', in the work of our own National Institute of Industrial Psychology, Miss Mary van Kleeck, of the Russell Sage Foundation, and other observers, have shown that more skilful management of men is essential to true rationalisation Heavy manual labour is being decreased and machine minding is becoming commoner, which may produce 'Robots' A new type of worker in industry is arising, and the old type of foreman and manager is already obsolete Again, the contraction of employment in the older processes is causing unemployment among the older men and women and the new processes are taking up the young Evidently new psychological problems are involved in rationalisation

In this connexion the establishment of the Institute of Industrial Administration is important [1] Evidently we cannot afford to trust to the appearance at the right moment of 'heaven sent' managers, for the management of men and the organisation of production require training, and we are now in the position of being able to use exact knowledge of methods In spite of differences in different trades and different traditions in different enterprises, there are some common factors in all industrial management Rationalisation implies the use in each enterprise of the knowledge of these common factors, but many employers and directors are still at the mental stage of those older teachers, who distrusted training for teachers on the ground that a teacher was born and not made The trouble is that an insufficient supply of 'natural' teachers is born and Nature supplies the art by which the deficiencies of Nature are amended So training and a test of competence are required for the supply of competent 'executives' in industry

There is, however, one of the most fundamental problems which the advocates of rationalisation and its practitioners are not considering The increase of productivity with less labour employed involves a decrease in the total of wages paid to the reduced number of workers, and wages are purchasing power Therefore the power to produce is increasing by methods which themselves decrease the power to consume If the same amount of production is obtained with only 60 per cent of the labour, then 40 per cent of the former number of workers have lost their power to purchase, and the unemployment benefit only just barely

[1] Registered Office 47 King William Street, London, E C 4

keeps their purchasing power at a minimum Now, most of the active business men who are rationalising are 'employers' or organisers of production, rather than commercial salesmen They tend, therefore, to aim in rationalisation at restricting the use of the new productive power to meet a shrinking market Profits are thus secured by preventing the use of productive power Not simply are 'less economic' enterprises closed down, but the whole of a great organisation may be used to cut production to the size of the market, and since less labour is needed every day, the market shrinks Unemployment is breeding unemployment

This is a problem of price rather than cost There is a need for house room and clothing which cannot become 'effective demand', to set the productive power going, because those in need have not purchasing power at the existing prices But there are ways of reducing prices, so that the gain from reduced costs may not all be pocketed by the producers, but may accrue to the final consumer It follows that for truly scientific consideration of the factors involved, we need a rationalisation of the market The use of credit, instalment buying, increased advertisement, and a changed education may be good or bad as means for reducing prices, but clearly some such means must be studied, if the rationalisation of the productive process is not to leave on our hands a problem greater than the problem it solves Traditional 'trial and error' in economic policy should give place to the scientific consideration of the market by an economic general staff

Rationalisation involves not merely greater efficiency of the labour used, and greater competence in management, but also large scale, long sighted economic policy Such policy must be based upon a scientific knowledge of the resources, natural and human, available for producing goods and services, a knowledge which the traditional 'business man' does not possess because he has confined his attention to his own enterprise The traditional economic science may also be proved to be inadequate for true rationalisation, since it rests upon a fatalism with regard to the market which is the result of a neglect to study 'consumption' Rationalisation in economic policy cannot omit to consider the needs which are not in fact 'effective demand', for there is no reason to suppose that a 'hidden hand' will provide a market if we think only of costs and not of prices, and there is every reason to believe that we can, if we give our minds to it, increase the market to meet increases of productive power

Agricultural Science and Grassland

The World's Grasses their Differentiation, Distribution, Economics and Ecology By Prof J W Bews Pp xii + 408 (London, New York and Toronto Longmans, Green and Co Ltd, 1929) 21s net

RECENT years have witnessed quite a remarkable development in the application of science to questions associated with the utilisation and management of grassland The agricultural scientific workers of nearly all countries of the world appear to be devoting more and more attention to the manifold problems connected with grassland, and nowhere is this in greater evidence than in Britain and in the overseas territories of the British Empire So great is the volume of research now in progress relative to grassland, that it is no unusual thing to hear the view expressed that our workers in agricultural science are perhaps running the risk of neglecting the no less pressing problems of arable farming Apart altogether from the fact that there is an immense amount of leeway to be made up in connexion with the critical scientific study of grassland, and to the further fact that grassland contributes so materially to the agricultural wealth of nations, it should never be forgotten that pastures and meadows, and still more so temporary leys, have always taken, and are likely always to take, an important place in most schemes of husbandry largely based on the use of the plough Perhaps a truer criticism relative to the vast amount of research in progress is that it is being conducted from so many different angles, and without relation to any general philosophical attitude towards the grassland problem as a whole

The appearance of Prof J W Bews's important book on 'The World's Grasses" is, on this account, profoundly opportune—for in the last resort all studies of grassland must come back to the contributing species, and notwithstanding the fact that leguminous plants are of great importance, and although it is becoming to be realised to an ever increasing extent that numerous plants belonging to other natural orders are of decided significance, yet the fact remains that it is the order Gramineæ that sets the seal to the world's grasslands

The value of Prof Bews's book at the present juncture is that it at once rivets the attention of the student of grassland on species *qua* species—the bricks and mortar with which any proper appreciation of the grassland complex can alone be

built The merit of this arresting book lies in the fact that our author has not been content merely to describe the grass species of the world, and to prepare a very carefully planned key to the tribes and genera, but he has boldly assumed the rôle of systematist, ecologist, and physiologist, and has welded the immense amount of evidence brought forward into a definite thesis—a definite guiding principle—which is presented in the stimulating form of an endeavour to trace the phylogeny of the various genera and their evolution in relation to ecology

It follows that Prof Bews has written what is at once a book of reference and a highly suggestive treatise on the etiology of the world's grasslands The former aspect of the book is embodied in Chap iii with its key to the tribes and genera—a fine achievement this, to bring all the genera of so large an order into one key—and Chaps iv, v, and vi, which deal with the distribution, ecology, and economics of the genera

These chapters introduce no controversial subjects, and alone render the book one which should be available to all workers concerned with grassland For here is a remarkably trustworthy body of information collected in the compass of 167 pages (rather less than half the book) The nature of the treatment calls for generalisation, which must inevitably in certain particulars be somewhat indefinite, and perhaps more especially where particular species are concerned Thus, for example, it is stated that *Poa trivialis* is closely allied to *Poa pratensis* "and has the same habit", whereas the former species spreads by means of stolons and the latter by means of rhizomes An error, which from the context would seem to be quite accidental, occurs when it is said that *Bromus secalinus* is sometimes grown for hay The statement would be correct for *B arvensis*, which is mentioned in the preceding sentence

To attempt any detailed and unbiased criticism of the remaining—the challenging—chapters of the book is itself difficult, for specialists in different branches of botany are bound to hold their own views, and it would be almost unfair to the author, who advisedly has adopted the synthetic treatment and lays no claim to being a specialist in all the subjects necessarily brought under discussion All will agree, however, that Prof Bews's unique knowledge of the Gramineæ as revealed on almost every page of the book, affords a complete justification for his manner of treatment—indeed he may almost be said to have placed himself under an obligation to take a philosophical view of his subject—and consequently the real achievement of these chapters turns on the fact that he has envisaged our grasses and grasslands from a fundamental and really scientific point of view

We cannot, however, resist the temptation to quarrel mildly with Prof Bews on certain points of detail, and the more readily since he almost invites us to do so The main argument adopted from a phylogenetic point of view appears to be that in general a reduction in the inflorescence or in any of its parts, or the hardening of the structures surrounding the paleæ, indicates an advance upon the primitive form, while the primitive habitat is taken to be moist (or even wet) and warm Advance, then, means the capacity to occupy the extremes of dry and cold habitats The chief drawback to the whole system is of course that it necessarily places great emphasis on floral similarity and dissimilarity, and perhaps does not lay sufficient stress on vegetative characters The system adopted is perfectly satisfactory for taxonomic purposes, in which connexion there can be little objection to genera as dissimilar as *Phleum* and *Agrostis*, which are alike in little else but the uni floral condition of the spikelet, both being placed in the Agrostideæ Similarly, on the basis of the organisation of the inflorescence, *Lolium* undoubtedly finds a fit place in the Hordeæ, and yet it might reasonably be argued that phylogenetically it comes much nearer the genus *Festuca* in the Festucineæ than to any member of the Hordeæ, on account of the fact that *Lolium perenne* has been successfully intercrossed with three species of *Festuca* These examples at least show the danger—and a danger which the author has himself emphasised—of forcing phylogenetic interpretation upon a system of classification based essentially upon floral characters, and the danger is perhaps the greater because in the main such a system has the undoubted appearance of being natural

In his wholly admirable discussion on wide grassland types in their ecological aspects, the author is undoubtedly faced with certain fundamental difficulties—difficulties which in some cases are hard to surmount, especially when it is attempted to correlate phylogeny (based on taxonomy) with ecological facts In our view, the author has somewhat added to his difficulties when, for example, discussing temperate and alpine 'meadows' and 'pastures', he attempts to regard these as separate entities We thus find such a plant as *Lolium perenne*, so characteristic of the best old British grasslands, excluded from 'meadows'—but these characteristic swards would seem inevitably to fall

into the 'meadow' category, particularly since *Cynosurus cristatus* is regarded as a constituent of meadow herbage If it is legitimate, and we think it is, to include *Lolium perenne* in the 'meadow' category together with *Phleum*, *Alopecurus*, and other species, it would then also be incumbent upon us to contradict the statement that "meadow grasses are also relatively primitive types"

In dealing with the vast and relatively lightly grazed areas of grassland, the biotic factor—man and his grazing animals—is often of relatively slight significance, but the author has shown how greatly these grasslands may be altered when this factor comes into play When dealing with temperate 'meadows' and 'pastures', and even with mountain and alpine grasslands, the author has perhaps not taken the biotic factor sufficiently seriously into consideration, for wherever grazing reaches any sort of intensity, wherever domesticated animals come upon the scene, the biotic factor undoubtedly ranks with the edaphic and climatic as of supreme importance

Festuca and *Poa*, "regarded as representing the most primitive of the ordinary grasses", yet have a very wide range in temperate regions The dominant place taken by *Poa pratensis* over considerable areas in North America (areas which by no means represent particularly primitive habitats), for example, is due wholly or in very large measure to the biotic factor

It is not easy to estimate the extent to which the human biotic factor has influenced mountain, and particularly alpine grassland, but the occurrence together of *Poa alpina* and *Phleum alpinum*—two species of very different taxonomic-phylogenetic position—under alpine conditions may perhaps be considered significant rather than merely interesting

These closing remarks have been made solely to indicate the magnitude of the task which the author had set himself For this very reason, because Prof Bews has written this book, all who are interested in the science of grasses and grassland are placed under a deep sense of obligation to him The illustrations (the subjects of which have been well chosen to show the range of differentiation exhibited by the tribes and genera), the bibliography (which is extensive and in the main complete, despite the rather unexpected omission of Sinclair's "Hortus Gramineus Woburnensis"), and the index (the chief references to the genera are shown in heavy type) are worthy of the book and of the author

Pliny as a Chemist

The Elder Pliny's Chapters on Chemical Subjects Part 1 Edited, with Translation and Notes, by Dr Kenneth C Bailey Pp 249 (London Edward Arnold and Co, 1929) 12*s* 6*d* net

IN the preface to this delightful and scholarly volume, Dr Bailey complains that recently published histories of chemistry usually fail to give fair consideration to the chemical knowledge of the Romans Admitted, however, that Roman chemistry does generally receive scant notice, the reason surely lies in the comparative lack of material rather than in any wilful neglect on the part of the historian Rome has, in short, left us no grand chemical generalisations or striking chemical discoveries An eminently practical people, the Romans were quick to perceive the value of applied science, and Roman artificers and engineers were unequalled in skill and ingenuity Yet when the historian of chemistry attempts to lay his finger on definite advances which the Romans made, he finds it an almost impossible task Perhaps here and there a recipe is given that cannot be paralleled in an earlier age here and there is a process which seems particularly appropriate to special circumstances, here and there an apparently new operation is described, but that is all Roman craftsmen for the most part merely applied old knowledge with new efficiency, and Roman thinkers were more attracted to the laws of the State than to the laws of Nature

To understand later developments, it is nevertheless important to be able to gauge accurately the scope and content of Roman empirical chemical knowledge, and for this purpose Pliny's "Natural History" is invaluable The most modern translation of the whole of this great work is that of Bostock and Riley, published in 1855 and now almost *introuvable* In the long interval that has elapsed, the advance of both chemistry and the history of chemistry has been extremely rapid, and, as Dr Bailey justly observes, the historian now has at his disposal weapons so much more powerful as to warrant a new translation We are fortunate in that Dr Bailey has himself undertaken the task of editing and translating the chemical sections, the difficulties of which are numerous and often very perplexing

Pliny, whose numerous public activities culminated in his appointment as Admiral of the Fleet, collected a vast amount of miscellaneous information, and as he was by no means deficient in the critical faculty, much of it is closely accurate

The chemical sections, scattered throughout the "Natural History", are consequently in general plain statements of fact, largely free from the superstitious embellishments so exasperating to the student of early chemistry It is true that the statements are often erroneous, but they are at least not deliberately mystificatory

Primitive chemical writings present two categories of difficulties first, the establishment of the text itself, and second, the interpretation of technical terms and obscure allusions in the text when established Dr Bailey has not shirked either variety, and where the problems with which he was confronted proved insoluble, he has not hesitated to admit failure, these cases are, however, few, and are usually of such a nature as to seem permanently incapable of solution

As interpreted by Dr Bailey, Pliny's chemical knowledge surprises us by its extent and more particularly by its accuracy in detail As an example of the latter, it may be noted that Pliny mentions that the colour of minium (mercuric sulphide) is changed by heating but is regained on cooling, that it is, however, completely destroyed if the minium is heated with lime, that minium is turned black by the action of light, and that mercury may be obtained from it either (*a*) by the action of heat, or (*b*) by triturating it with vinegar in a copper mortar with a copper pestle Dr Bailey, with admirable thoroughness, tested the second of these methods experimentally He finds that in the cold the reaction is very slow indeed, but that on heating it takes place readily enough, copper sulphide being formed, while the surface of the copper turnings becomes covered with a copper-mercury amalgam, from which the mercury may be driven off by heating

The sections on salt contain many interesting points Thus in Book xxxi para 67, Pliny states that four *sextarii* of water will dissolve one *sextarius* of salt and no more—one of the earliest estimates of solubility (though not a very accurate one) As to the celebrated *sal Hammoniacus*, Dr Bailey agrees with Beckmann, Stillman, and others in believing it to have been an impure variety of sodium chloride, he says that we have no proof that the name was used of ammonium chloride before the tenth century A D Among Arabian writers, ammonium chloride is generally called *nushadhir*, but this is not infrequently equated with *milh armaniyyu* or 'Armenian salt', between the latter and 'Hammoniacal salt' there is an obvious possibility of confusion

'Chrysocolla', which travelled via Islam to medieval Europe, where it emerged as *harsufle*, is identified as malachite or copper carbonate, which is known to have been prepared in the way described by Pliny The natural product, says Pliny, although harder than the artificial, can be dyed with the herb called *lutum* (*Reseda luteola*) Dr Bailey finds that this is indeed so, and that the dyed compound possesses a fine emerald green colour far superior to that of the original malachite Noteworthy is the name *uva* for natural chrysocolla, doubtless a reference to the botryoidal masses in which malachite often occurs

On gold, Pliny has a great deal to say, much of which is—as the modern abstractor would express it—'polemical' against Roman habits of luxury He mentions, however, that the best proof of the purity of gold is a high melting point (*quam difficillime accendi*), that nothing can be beaten into thinner leaves, that it will not rust, and that brine and vinegar have no effect upon it, but that it is less dense and less malleable than lead

The present volume, which forms the first part only (Books ii xxxiii), contains the Latin text and English translation on opposite pages, together with a short introduction, 86 pages of notes, and a useful index We trust that Dr Bailey will soon complete the task he has so successfully begun, for, in addition to the intrinsic interest of the subject, it is pleasant to meet again the 'portly and somewhat pompous' Pliny, who, though a bookworm and a pedant, came to an untimely end through his insatiable scientific curiosity

E J H

Cicadas

Insect Singers a Natural History of the Cicadas By Dr J G Myers Pp xix + 304 + 8 plates (London George Routledge and Sons, Ltd, 1929) 21*s* net

THIS work, notwithstanding its title, is not a popular book, but a serious scientific treatise on Cicadas Dr Myers seems to have read and digested practically everything written pertaining to these insects, besides carrying out a considerable amount of personal investigation of their structure and behaviour

References to Cicadas date far back into ancient mythology (tenth or eleventh century B C), and the two chapters on this subject form a scholarly dissertation The two succeeding chapters are devoted to external anatomy and internal anatomy respectively The much-debated subject of the

morphology of the head sclerites is not discussed, but the author adopts a reasonable interpretation of the parts concerned Dr Vogel's little known work, on the existence of chordotonal organs in the so called mirror of the tympanal organs, is dealt with in some detail It is of much importance, because it affords the only reasonable proof of the existence of any structures capable of sound reception among these highly 'musical' insects In dealing with evolutionary problems, the author concludes that the Cicadas are a very isolated group with no ancestors among any fossil forms yet discovered the earliest known fossil Cicada is from the lower Cretaceous, and there is a wide gap until the definitely modern types appear in the Oligocene amber beds

In the account dealing with life histories, the difficulties involved in recognising the nymphs of different species are stressed, but in so far as the New Zealand Cicadas are concerned, Dr Myers finds that they can all be separated by characters afforded by the fore femora We also observe that he dispels the deeply imbued idea that Cicadas pass through a quiescent pre imaginal instar the so called 'pupa' being nothing more than the nymph in its final instars

Passing over a number of sections dealing with distribution, relations with plants, insect and vertebrate enemies of Cicadas, etc, the concluding chapters are concerned with sensory perception and psychological problems Especial attention is given to the 'song' of these insects, and the author has carefully analysed the various notes of a number of species and expressed them in the form of graphic music The chief rôle of the song is, he believes, an assembling one, but he also concludes that it operates to arouse in one or both sexes the emotions necessary to consummate the sexual act At the end of the book there is an extensive bibliography, the bulk of which is partly owing to the inclusion of references to all the taxonomic papers wherein new species of these insects are described A combined author and subject index follows

As a whole the book is a very good one, it is crammed with information and with extracts from the publication of different authorities, but it is not exactly a readable volume, but rather one which will be resorted to for reference Most of the illustrations are line figures, somewhat heavily drawn, and lacking in finer detail They give the impression of being hurriedly executed, but they serve to explain the points intended

A D I

Our Bookshelf

Australian Nature Studies a Book of Reference for those interested in Nature Study By Dr J A Leach Second edition, revised and reset Pp vii + 525 (Melbourne and London Macmillan and Co, Ltd, 1929) 12s 6*d* net

THERE is in this book an abundance, indeed an excess, of material from which teachers, either in Great Britain or in Australia, can construct courses About one third of the volume is devoted to plant life, rather less than half to animal life while the remainder is concerned with studies of inanimate Nature, such as soil, wind, water, denudation, and physical geography An essay on Nature study in education, and a suggested course in the subject, form an appendix This last should be consulted at the outset by those proposing to adopt the book

Amid the many styles and modes of address employed by the author, whose death, we understand, has occurred since his book appeared, we are puzzled, in spite of the sub title, to know for what class of readers he intended his book Books of these dimensions and at this price are not for pupils of tender years Yet frequently the mode is on heuristic lines, questions and instructions being addressed direct to the pupil Elsewhere the address is to the teacher while repeatedly the dialogue style is adopted, an imaginary teacher Socratically leading an imaginary, gesticulating class Interspersed among these variations is the style usual in text books The effect of these changes is not pleasing, and wastage of space results Moreover, too much has been attempted, the lists of plants and animals are needlessly lengthy, while the brief notes on them are often of little value A careful study of fewer would have produced a more interesting and more educative work

The illustrations are numerous and helpful they need close attention, for much that in most books appears in the text is here condensed in them, but we have found no difficulty in grasping the significance of any one of them

Fables of the Veld By F Posselt Pp xi + 132 (London Oxford University Press, 1929) 6s net

MR POSSELT has collected these folk-tales among the natives of Southern Rhodesia—not from one, but from a number of tribes The tales are not grouped either under tribe or subject, but the tribal origin of each is given in the table of contents Happily, the author has made no attempt to 'improve' the material and has aimed at preserving the spirit of the original

The tales are distinctly readable apart from the many points of interest they present to the folklorist The hero of a considerable group is the hare, who displays the cunning of Br'er Rabbit, but, like that worthy, frequently overreaches himself The Tar Baby here appears as a tortoise who covers himself with bird lime in which the hare becomes entangled Other parallels with

Uncle Remus are numerous 'Throwing the bones', the ritual of the South African witch doctor, here takes the place of the 'Table be covered' formula in Grimm

Jute and Jute Spinning Part 1 *Production of Fibre, Cultivation, Batching, Preparing and Carding* By Thomas Woodhouse and Peter Kilgour Second edition Pp xx + 301 + 21 plates 20s net Part 2 *Drawing and Roving Frames* By Thomas Woodhouse and Peter Kilgour Pp xxiv + 350 + 19 plates (London Macmillan and Co, Ltd, 1929) 20s net

THESE two volumes form a very welcome addition to textile literature The authors have a thorough grasp of their subject and a sympathetic understanding of the needs of students As text-books, the student of jute spinning will find them most comprehensive Very few text books on textile subjects cover the ground so completely The practical man will also have a most reliable source of reference, as the various types of machines and workings have been described and discussed in detail The subject matter is well arranged and the wealth of detail is presented in a manner that makes the reading of it most interesting This latter is in itself no mean accomplishment The line drawings are very clear, and the value of the work has been enhanced by the inclusion of photographs that in many cases were taken in the mills Practically everything possible has been done to explain the principles underlying the various operations

In the main, Part 1 is the same as in the 1920 edition, but in order to bring the matter up to date, an appendix, wherein improvements and changes in 'batching' and 'carding' are recorded and discussed, has been added The chapter on motive power gives a reasoned summary of an important item in manufacture This will be greatly appreciated, as, generally speaking, such information is only obtained from a search through a number of books and, this search completed, the application to a particular trade or machine requires to be worked out

In Part 2 is described and discussed at considerable length a wide range of drawing and roving frames The comparison in the treatment of flax and jute fibres is most instructive

While the volumes are primarily intended for those in the jute trade, they will also be of much service to candidates for the diplomas of the Textile Institute and to many others The authors and publishers are to be congratulated on a most successful production We anticipate a wide circulation for the new edition

ANDREW R GEARY

Enzyme Actions and Properties By Ernst Waldschmidt-Leitz Translated and extended by Robert P Walton Pp xviii + 255 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1929) 20s net

PROF WALDSCHMIDT LEITZ has given a condensed description of the most important principles of the chemistry of enzymes and of the characteristics of the more important members of the group In other words, the material available has been selected and the viewpoint adopted is that of the Willstätter school The translator has extended the original German text with the help of the author, so as to bring the volume up to date

An important aspect of the subject dealt with is that of the quantitative determination of activity by taking into consideration both the relative activity and the amount of material obtained, it has been possible to follow the enzyme through a series of purifications, with considerable success in the development of methods of preparation Somewhat less than half the text is devoted to the general properties of enzymes and their preparation the remainder considers the different ferments separately, the esterases, proteases, and peptidases, aminoacylases, carbohydrases, catalases, peroxydases, oxydases, and fermentation enzymes There are numerous references to the literature One point attracted our attention, the author is described on the cover as Waldschmidt, instead of Waldschmidt Leitz

This appears to be a very useful volume on the subject and should find a wide circle of readers, as enzyme activity plays a part in every field of biochemistry

The Zoological Section of the Nuzhatu l Qulūb of Hamdullāh al Mustaufi al Quazuīnī Edited, translated, and annotated by Lieut Col J Stephenson (Oriental Translation Fund, New Series, Vol 30) Pp xix + 100 + 126 (London Royal Asiatic Society, 1928) n p

THIS learned translation affords a vivid glimpse of the zoological knowledge current in Persia in the early half of the fourteenth century, and may be compared with the "Physiologus", so long the zoological text book of medieval Europe It discusses the appearance and properties of 228 different animals, and the accounts lean to the economic point of view, for the uses of animals and their parts in medicine and magic assume much greater importance than habits or structures Judging from the frequency with which certain diseases are mentioned in this primitive materia medica, Col Stephenson regards the following as among the commoner diseases of fourteenth century Persia cataract, corneal opacities, stone in the bladder, ringworm of the scalp, leprosy, quartan fever, tuberculous glands

Many of the animals described are figments of imagination, but with the substantial creatures all are grouped in a simple classification based upon habit and habitat There is very much of interest in these old descriptions we mention just two points It is strange that although 'domestic animals' include the cat and nine others, the dog is omitted, although subsequent references (p 34) show that it was used for several purposes, and there is a prophetic suggestion in the association of mosquitoes with malaria—"three mosquitoes given along with a quantity of gum for three days to one with quartan ague will take away the fever" (p 64)

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications]*

The Identity of the Colloidal Particles in Soap Sols and Jellies

TEN years ago we found that two portions of the same solution of soap could be brought into the states of either sol or typically transparent jelly respectively at the same temperature, and that such significant properties as conductivity, lowering of vapour pressure, concentration of sodium ion as measured with the sodium amalgam electrode, etc, were identical in both these states Sol and jelly differed only in mechanical properties such as rigidity and elasticity We therefore drew the obvious conclusion that the rigid structure of the jelly must be built up by progressive linkings together of the particles which pre existed in the sol (*Trans Chem Soc , London*, **117**, 1506, 1920)

Recently this subject has received much attention and our conclusion has been called in question However, we submit that the essential point has been entirely overlooked The whole question is whether or not it is possible to prepare specimens of jelly in which the typical mechanical properties of jellies are manifested without altering any of the quantitatively measurable properties of the original sol If this can be done our conclusion appears to be inevitable No attempt to attain such good specimens is recorded as having been made by the other investigators K Krishnamurti, in a recent letter to NATURE (Nov 2, 1929, vol 124, p 690), contents himself by saying that light scattering capacity is even more significant than any property we measured and that his specimens differed distinctly in this respect Now it is perfectly easy, as we showed, to obtain a soap solution in almost any desired degree of whiteness and opacity through curding or crystallising out, that is, through formation of innumerable excessively fine fibres of soap crystals like cotton wool on a much finer scale Parallel with this increasing whiteness, intensity of scattering and opacity goes a falling off in conductivity, etc Analysis of the mother liquor from which the curd fibres are crystallising, naturally shows that it is becoming correspondingly depleted in soap It is obvious that a soap curd is wholly different from a sol or jelly, and that the crystals are forming through the destruction and disappearance of the colloid which existed in the sol or jelly

We now therefore put on record that we have prepared samples of the same solution of sodium oleate, some of which were fluid sols and others typical jellies, but the light scattering of which was identical within the experimental error of a fraction of a per cent

For the measurements, we employed a 0 5 *N* solution of pure sodium oleate (made from metallic sodium, conductivity water and purest oleic acid prepared according to Lapworth) The specimens were illuminated by an arc, and the scattered light viewed through a large Schmidt and Haenach photometer with special Lummer Brodhun prism The intensities were matched by altering the width of the slits which were operated by micrometer screws, graduated into 560 divisions Interchange of sol and jelly in front of the same slit led to identical readings, plus or minus the small experimental error indicated above, when matched against any constant standard For example, the maximum divergences between sol and jelly are represented by readings such as 312, 314, 312, 314, for sol, jelly, sol, jelly, respectively Occasional specimens gave readings differing in the opposite direction At 24° the jelly is soft and could be made to flow, at 10° the sol and jelly show much greater light scattering, but are still equal to each other The jelly may be cut into pieces with a knife, whilst the sol is quite fluid The hysteresis in the change of light scattering of a soap sol with changing temperature mentioned by Krishnamurti is also exhibited by all other properties of soap sols, as we have repeatedly pointed out The final values, however, are reproducible when sufficient time is allowed

L Arisz (*Koll Zeit*, **7**, 49, 1915) found that the light scattering of solutions of gelatine both in sols and jellies changes greatly with time, temperature, and concentration without any discontinuity in the region of gelation Gelation then appears as almost irrelevant to the changes taking place in the colloidal particles and merely makes use of those present at the time

Our original observations and conclusions therefore stand and are not invalidated, as claimed, for example, by Hatschek (*Koll Zeit*, **48**, 246, 1929) in his work on cloudy agar gels or by Zsigmondy and Theissen (*Z anorg und allge Chem*, **179**, 266, 1929) on partially curded soap gels We would of course agree with von Weimarn (see E Iwasi, *Koll Zeit*, **43**, 70, 1927) in principle, that if two colloidal particles join even at a molecular point their composition or hydration must be to that minute extent altered Nevertheless, the piling or the cementing of bricks to form a larger structure is like the loose junction of particles of a sol to produce a jelly The formation of curd from a jelly is as drastically different an operation as would be the dissolution of the bricks in hydrofluoric acid or the fusion of them into a single casting

The Classification of the Primates

I HAVE for some time been interested in the classification of the Primates, from the point of view of a student of geographical distribution, and have suspected that the differences between the Platyrrhines and Catarrhines are more fundamental than is generally supposed, and that their resemblances may be due to convergence

Prof Elliot Smith's new classification, in NATURE of Dec 7, appears to take little account of the differences between the Platyrrhines and Catarrhines, as he unites the monkeys of both groups to form a sub order Pithecoidea, and separates the apes and man from the Catarrhines as a sub order Anthropoidea The purpose of this letter is to show that there are at least good reasons for other views as to the classification of the Primates Prof Elliot Smith is, of course, perfectly well acquainted with the evidence I will cite, but interprets it differently

J Thornton Carter (*Proc Zool Soc*, 1922) has studied the microstructure of the enamel of the teeth of the Primates, and has found that there are two types of enamel pattern In the Mascarene Lemurs, the Eocene Lemuroids *Pelycodus* and *Notharctus*, and the Catarrhines, the enamel prisms have straight edges, and are separated by a slight amount of interstitial substance In the Asiatic and African Lemurs (Lorisoids), Tarsioids (*Tarsius* and the Eocene *Hemiacodon*), and Platyrrhines, the prisms have wavy edges and are separated by a considerable amount of interstitial substance Carter emphasises the constancy of

the enamel pattern in natural groups, he writes, "In the long and well authenticated series comprising the ancestry of the horse, the microstructure of the enamel does not change, in spite of the modification of the teeth—Fossil rodents from the Eocene exhibit a close similarity in enamel structure to recent forms, and where, as in *Chiromys*, a Lemur has evolved a rodent dentition, the structure of the enamel still retains its Lemurine characters" I quote these remarks of Carter in order to show that it is not unreasonable to regard the microstructure of the teeth as of primary importance in the classification of the Primates A classification based on enamel pattern is

A Prisms with straight edges *Lemuroidea, Catarrhina*

B Prisms with wavy edges *Lorisoidea, Tarsioidea, Platyrrhina*

It may be noted that Gregory's description of the Eocene *Notharctus* (*Mem Amer Mus*, **3**, 1920) leaves no doubt that it belongs to the same group (*Lemuroidea*) as the Mascarene Lemurs, with which it agrees in enamel pattern

As regards the groups with wavy enamel prisms, a memoir by Beattie (*Proc Zool Soc*, 1927) on the anatomy of *Hapale* is of interest as showing the close relationship between Tarsioids and Platyrrhines According to Beattie the similarity in structure of the skull of *Hapale* and *Tarsius*, particularly of the nasal region and the orbit, is so close, that when other similarities are considered, it is evident that these two animals are nearly related

The series *Lorisoidea Tarsioidea Platyrrhina* therefore offers no difficulties But it must be admitted that the Catarrhines are the most advanced group of the Primates, and that most of their characters may be interpreted as further developments of Platyrrhine structure Nevertheless, the microstructure of the teeth indicates their direct derivation from the Lemuroidea, which stand at the base of the Primate stem

The absence of monkeys from the Tertiary beds of North America has led some authorities to explain their present distribution by means of a Tertiary land connexion between Africa and South America This hypothetical connexion is unnecessary if the monkeys are diphyletic Tarsioids were present in North America in Eocene times they may have entered South America when the connexion with it was established at the end of the Oligocene, their earliest known Platyrrhine descendants are found in Miocene deposits Catarrhines were present in Africa in early Oligocene times, but are unknown in Eurasia before the Miocene Probably, like the Proboscidea, they originated in Africa during the Eocene, when that continent was isolated

Evolution and Evidence

THE transfer of Down House to the British Association led me to place on record elsewhere a few memories intended to illustrate my father's character One recollection I refrained from adding, both because it related to science and because at the critical point in my story my memory becomes hazy Here it is, however, in case NATURE should care to publish it

On more than one occasion I remember my father either pointing out or alluding to a part of a meadow where year after year the vegetation was different from that found in the immediate vicinity This he did with the object of indicating that though each of these different vegetations was evidently better adapted than the other to its own locality, yet no explanation of this fact could be given, though all was taking place under our eyes Then, with more warmth than was usual with him, he would show how weak in the light of such observations were certain arguments often brought forward against his views But what were these arguments? It is here unfortunately that my memory becomes defective

All that I can do is to mention a few fallacious arguments which I *believe* are *illustrative* of what was in my father's mind when he spoke A wonderful record now exists of the stages in the evolution of the horse, and yet we cannot indicate in what way the later forms were better adapted to their surroundings than were the earlier ones Hence, so it is urged, this evolutionary movement cannot have been the result of improvements in adaptation due to natural selection But if we cannot point out the nature of many of those adaptations which we know to exist in the organisms that surround us, is it not futile to hope often to be able to recognise adaptations in the imperfect records of animals which existed millions of years ago in changing environments concerning which we are very ignorant?

Another example is the erroneous reasoning often met with in regard to orthogenesis We should expect to find that somewhat similar species would be somewhat similarly and continuously changed in the process of evolution in order to make them better and better adapted to their somewhat similar surroundings, and this explanation of the parallelism and continuity of direction of certain evolutionary changes which took place in the past is not proved to be false by the fact that in none of the organisms concerned can we demonstrate that an improvement in adaptation was really taking place Then again it has been asserted that no use can be assigned to certain first recognisable modifications in fossil remains, although they seem to have been the foundations on which were built certain evidently beneficial structures which appeared in subsequent ages But if we cannot indicate what are the relative advantages of the major differences between the plants inhabiting different parts of our meadows, why expect to be able to indicate the value of minor evolutionary changes which occurred in the remote past?

If at the risk of uttering biological platitudes I add a few more words, it is only in the hope that I may be putting into modern dress some thoughts the underlying basis of which I probably absorbed years ago at Down We may regard each individual organism as springing from a group of genes fortuitously selected, in accordance with certain rules, out of the limited number of different kinds of genes which are to be found at any one time in the species in question, whilst the germinal material as a whole had been acting as a store house for the small mutations which had taken place from time to time in the past Some individuals will be better and some worse adapted to their surroundings, and the superior will survive in a biological sense in greater number than the inferior When the next generation is being formed, the groups of genes thus selected will be to some extent dispersed throughout the whole interbreeding group in question But the greater the number in the species of those genes which together would make a favourable combination, the more often would these superior individuals appear as the result of the fortuitous reassembly of such groups of genes

If we take any two antagonistic qualities of the same individual, such as strength and agility, selection is always tending to produce the appearance of the best possible compromise between them, and this optimum compromise may vary in accordance with very small differences in surroundings Different

races will therefore begin to arise in different localities, for example, the weaker and more agile forms becoming more numerous where the nature of the country especially favours rapid movement. Or the same kind of differentiation of forms may take place in consequence of a different use of certain elements in the environment being made by different individuals. After this bifurcation had thus begun, other qualities would have to be differently modified so as to be brought into harmony with these changes, thus causing a further increase in differentiation; for example, in order to make the best adaptation, the weaker and swifter forms might be benefited by a change in some third quality different from that which would be beneficial to the stronger and slower types. When once bifurcation had begun, the paths along which the evolutionary changes in these local races was taking place might thus become slowly more and more divergent. We feel no jar at a railway junction, and yet we may before long be miles away from where we should have been if the points had been set differently. In somewhat the same way, the circumstances which millions of years ago turned the current of evolution in one direction rather than in another have, as a rule, left no relic by means of which they could now be recognised, even though we can clearly see the differences in the utility of many structures which afterwards came into existence.

To sum up, at Down I was led to believe that negative evidence, or rather the absence of positive evidence, can do but little towards condemning any evolutionary theory; whilst it is to positive evidence that we must look in order to decide whether in our existing state of knowledge natural selection is to be accepted as the most probable hypothesis in order, in the main, to account for such adaptations as are clearly recognisable in Nature.

Gaseous Combustion

SOME years ago we began to investigate certain aspects of gaseous combustion phenomena in closed vessel explosions and in gas engines with the aid of flame photography. Our experiments, however, appeared to lead to absurd conclusions when the flame photographs were interpreted in the light of the view that the emission of luminous radiation in gases results directly from chemical combination, and we have since been attempting to trace the origin of the luminous emission.

We are now clear that the intensity of the luminosity in an exploded gaseous mixture is wholly, or almost wholly, dependent upon its temperature (as inferred from its pressure), and that the amount of chemical combination taking place at any time has little effect, if any, upon the intensity of the emission at that time; indeed luminosity is manifest in our exploded gases at a time long after that at which combination (as inferred from the chemical analysis of rapidly cooled samples) has been completed, and if the gases in this state are adiabatically compressed they become brilliantly luminous again. Flame photographs, therefore, while they give invaluable information as to flame propagation in inflammable mixtures, yield no information as to the chemical state of the gases behind the flame front, but merely indicate their temperature.

The work of Pringsheim and others, however, has shown that the more permanent gases do not become self luminous when heated externally to temperatures at which luminosity is manifest in our exploded gases. We are thus led to infer that molecules after combination are in an abnormal condition and that in this condition the luminous vibrations of which they are capable are excited by much softer collisions than those necessary to excite the corresponding vibrations in normal molecules.

Such an inference would perhaps be easy to accept were it not for the fact that we have to postulate a very long life history for the abnormal molecules (when the combination takes place wholly in the gaseous phase). We have, for example, recently made an explosion experiment under conditions such that cooling after maximum pressure took place very slowly in which luminosity was estimated to last for at least 14 seconds after maximum pressure, and we have little doubt that this period could be considerably extended by arranging for still slower cooling.

That chemical combination in the gaseous phase results in the formation of long lived abnormal molecules seems to be supported by another series of experiments which we have made. In these experiments continuous records of the temperature of thin platinum rhodium wires immersed in the inflammable gases were taken during explosion and subsequent cooling and correlated with continuous records of pressure, from which, of course, the mean gas temperature could be estimated. We found that wherever the platinum wire was placed in the explosion vessel, and even when the most violent turbulence was arranged for in order to secure uniform temperature distribution in the exploded gases, the temperature of the wire was some hundreds of degrees (often 500° C. and more) above the gas temperature (as inferred from the pressure) both during explosion and for some seconds afterwards, and therefore long after all chemical combination had ceased. Similar experiments were made in a gas engine with like results. It seems possible to account for these results only by assuming that the molecules after combination hold an excess of internal energy which can be rapidly unloaded upon the surface of the hot platinum wire when they come in contact with it, and in view of the fact that the phenomenon may last for some seconds, it would appear that the molecules persist in this condition for some time when in the gaseous phase.

Reviewing our work as a whole, we think that the most probable explanation is to be found in the suggestion that combination results in the formation of molecules of carbon dioxide and water of abnormal *structure*, which may persist for some time when in the gaseous phase, but pass instantaneously into molecules of normal structure on coming into contact with a hot surface.

Briefly, our suggestion is that the overall process of combustion may be broadly analysed into two stages. The first (the combination stage) may be represented thus

$$\boxed{A} + \boxed{B} \longrightarrow \boxed{A}\,\boxed{B} + (H - x)$$

where H is the heat of combustion, and the second stage (which in the gaseous phase may take many seconds), thus

$$\boxed{A}\,\boxed{B} \longrightarrow \boxed{AB} + x$$

If A and B represent atomic nuclei and $\boxed{}$ an electron atmosphere, $\boxed{A}\,\boxed{B}$ gives an indication of a possible type of abnormal structure and $\boxed{AB}$ that of the normal structure. For $\boxed{A}\,\boxed{B}$ it will be remembered we have to postulate a considerable stability in the gaseous phase, but it may be that the stability is apparent rather than real, and that the apparent stability is due to continual dissociation and recombination brought about by collision or to continual interchange of partners with neighbouring molecules.

The platinum wire experiments suggest that x may be an appreciable fraction of H, and we hope presently to test this by calorimetric methods both in closed vessel explosions and in a gas engine

An account of our experimental work has been prepared and will be published shortly

It is of interest to note that our platinum wire experiments suggest that the temperature (translational energy) of a Bunsen flame may be considerably less than 1800° C, which is the usually accepted figure

The Mechanism of Electrolytic Rectification

UP to the present, the two most acceptable hypotheses which have been advanced to account for the electronic valve action of electrolytic rectifiers are (1) the hypothesis of Burgess and Hambuechen, and (2) that of Gunther Schulze The first accounts for the high anodic resistance, and the consequent rectification of alternating currents by assuming the formation on the anodes of an oxide hydroxide film pierced with small holes or pores which grow smaller when the electrode functions as the anode, and larger when it functions as the cathode, thus providing a variation in electrical conductivity correlated with the direction of the current The second hypothesis, commonly known as the gas-layer hypothesis, assumes the formation of a porous oxide hydroxide film on the surface of the active electrode, in the pores of which oxygen gas is occluded While functioning as the cathode, the electrons are freely discharged from the metal through the gas layer, whereas, since electrolytes contain no free electrons, current can only pass in the opposite direction by forcing the anions through the gas layer that they may liberate their charges to the metal—an action which demands the expenditure of very considerable energy

During intensive work over the past four years in a successful attempt to make available the important electronic valve action of aluminium and some of its alloys, freed from the former defects which, hitherto, have made it of little practical value, the mechanism of electrolytic rectification has been studied microscopically, and from these studies it appears that neither of the current hypotheses of electrolytic rectification are quite correct

The chief trouble with the aluminium rectifier, both in action and while under observational investigation, has been the use of electrolytes which on electrolytic dissociation liberate ions that readily attack and combine with the electrode metals

By using a special electrolyte which exhibits electrolytic reversibility with anodes of aluminium or aluminium alloys and cathodes of 'passive' steel (the subject of Patent No 284039 and others pending) it has been found that the internal resistance, together with the chemical stability of the cell, remains constant, and that the oxide hydroxide layer on the aluminium does not, to any appreciable extent, increase in density during action

Under these conditions the surface of the anodes in action can be seen to acquire an exceedingly thin oxide hydroxide layer below which, here and there on the metal surface, small 'cushions' of gas are formed One side of the gas cushions is in contact with the metal surface while the other is in contact with the overlying layer When as the cathode, electrons pass from the metal into these gas cushions, they penetrate the gas, and piercing the oxide-hydroxide layer, in ionic linkage, pass as cations to the anode The resultant condition of the active electrode is that the metal surface is covered by the oxide hydroxide film which, at various situations, is pierced by small holes immediately over the small cushions of gas The minuteness of the holes, the surface tension and gravitational pressure of the electrolyte, retain the gas within their chambers, and the unidirectional conductivity of the gas operates between the metal surface and the electrolyte

Thus it would seem that the hypotheses of Burgess and Hambuechen, and of Gunther Schulze, are both partially correct, and that a combination of these two hypotheses is the true explanation Further proof of this has been found in studies of what occurs at the 'sparking voltage', for then the dancing scintillation denotes the disruption of the gas cushions, the renewed access of electrolyte to metal surface, the re formation of the rectifying gas points, and the sequence of subsequent disruption and re creation

Globular Lightning

I HAVE recently had an opportunity of investigating what would appear to be a case of globular lightning, and as this phenomenon is relatively rare, it seems of sufficient interest to record

In the afternoon of a day early last December, when there was a severe lightning storm in Liverpool, Mr Holder and his sister were sitting in the morning room of their house Browside, Mossley Hill, just

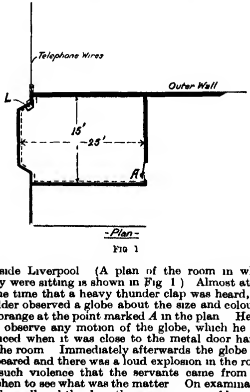

FIG 1

outside Liverpool (A plan of the room in which they were sitting is shown in Fig 1) Almost at the same time that a heavy thunder clap was heard, Mr Holder observed a globe about the size and colour of an orange at the point marked A in the plan He did not observe any motion of the globe, which he first noticed when it was close to the metal door handle of the room Immediately afterwards the globe disappeared and there was a loud explosion in the room, of such violence that the servants came from the kitchen to see what was the matter On examination of the wall and the door there was no sign of burning, but there was a strong smell similar to that which is commonly observed near Wimshurst machines or with ozonair apparatus The phenomenon is similar in character to those described by Dr Russell in his

presidential address to the Institution of Electrical Engineers in 1924, and by Dr Simpson in his review of Dr Walther Brand's book on ball lightning (NATURE, vol 113, 1924, pp 677 678)

It is difficult to suggest a satisfactory explanation of this phenomenon The only one that has occurred to me is that the lightning discharge induced a high frequency current in the telephone wires which were carried from the side of the house to a pole about 50 or 60 yards distant, and that this high-frequency current produced something like standing waves in the telephone lead (shown as a dotted line in Fig 1) If an antinode of pressure was formed at the point A, something analogous to globular lightning might have been produced at this point and thus have given rise to the phenomena observed

The windows of the house were not open at the time and it is therefore evident that the discharge must, in some way, have been produced inside the room Its general character corresponds fairly closely with the descriptions of globular lightning given by Dr Russell and others, namely, "a sphere of incandescent gas of a dull reddish colour"

Periodicity of Leaf-fall in Singapore

DURING the last two years I have kept regular observations, in the Singapore Botanic Gardens, of the behaviour of individual trees of species which show a marked periodicity of leaf development and leaf fall I hope to publish a full report after three years, but a brief account of the results already obtained may be of interest

Some of the trees are species of wide distribution, or exotic species, which in climates with a regular annual dry season have a leaf period of twelve months Most of these species in Singapore have periods of less than a year For example, the following are the approximate dates on which a tree of *Adenanthera pavonina* (Leguminosæ) has begun to produce new leaves, after brief leafless periods

	27 8 1927	22 3 28	21 10 28	28 4 29
Intervals	6 8 months	7 months	6 2 months	

The tree is now (Nov 1929) losing its leaves again This species is recorded by Wright as being annual in its behaviour in four successive years at Peradeniya, Ceylon, its new leaves developing there between November and January The tree in Singapore has flowered freely with every new crop of leaves, and has borne a full crop of ripe fruit before leaf fall

I have records of the behaviour of trees of a number of different species, and in some cases of more than one individual of a species The majority of the trees keep to fairly constant periods of their own, and trees of the same species often synchronise in their periods, but not always, where they differ in times of leaf-fall, trees of the same species usually have periods of approximately the same length Some individuals, however, appear to differ constantly by a small amount in the length of their periods from others of the same species For example, of two trees of *Cratoxylon formosum* (Guttiferæ), one has had periods of 9 3 and 9 2 months, the other of 8 5 and 8 3 months

In some species where the lengths of successive periods are very different, it appears that the occurrence or absence of flowering has a marked effect on the length of the periods In the cauliflorous *Ficus polysyce*, leaf period and fruit-period appear to be quite independent of each other Trees with a strictly annual period appear to be rare, either among native or introduced species Examples of annual behaviour are three very large trees of the family Leguminosæ, *Koompassia malaccensis*, *Parkia Roxburghii*, and *Hymenæa courbaril* Of these, the first named has produced new leaves in September in three successive years, and the other two in February Some Malayan species have periods of considerably more than a year

The regularity of period, usually not annual, is undoubtedly connected with the very uniform climate of Singapore, both as regards temperature and rainfall Though on the average the distribution of rain throughout the year is very uniform (there being no regular dry season), no two years are alike, I cannot, however, see any connexion between the leaf periods of any of the trees observed and the changes of rainfall

A First Order Solid Phase Reaction

IN the course of an investigation on the kinetics of the thermal decomposition of ozone sensitised by the presence of bromine vapour, a very interesting reaction came to light Under certain conditions as to temperature and concentration of ozone and bromine (see *Z f anorg Chem*, 182, 182, 1929, *Z f Elektrochemie*, 35, 651, 1929), it was found that the bromine disappeared slowly but quantitatively from the gas phase and was deposited on the walls of the containing vessel as a solid oxide of bromine (*hitherto unknown*) Under these conditions of complete oxide formation, the residual ozone decomposed at a constant rate until nearly all of it had disappeared The final result can be represented as $2O_3 \rightarrow 3O_2$

The magnitude of the constant rate portion of the reaction was found to be directly proportional to the concentration of bromine originally present, that is $+\Delta p/\Delta t = k(Br_2)$, and therefore to the mass of bromine oxide crystals on the wall The concentration of bromine was varied a hundredfold (0 3 mm to 30 mm Hg) The rate is independent of the amount of surface, kind of material used for the reaction vessel, and oxygen, foreign gases, and ozone concentrations over a large range

It was shown that the ozone decomposition does not take place in the gas phase Nor can it be a surface reaction in view of the ineffectiveness of large increases in surface Furthermore, were the latter the case, one would have expected the rate to deviate from the above relation as the surface became saturated with oxide Even though exceedingly thick layers of oxide were deposited, the strict proportionality held

We have been led, therefore, to the conclusion that the reaction is of the first order and takes place in the solid phase of the crystals, that is, a definite fraction of the oxide decomposes per unit time *This appears to be the first known reaction of this kind* For a given amount of oxide the reaction appears to be zero order, because any oxide which has decomposed is immediately re formed by ozone, maintaining a sensibly constant amount of oxide

The presentation and discussion of the results of this work, which was done at the Physical Chemistry Institute of the University of Berlin, will appear shortly in the *Zeitschrift f Physik Chem*

A New Relativity Theory of the Unified Physical Field.

I HAVE succeeded in applying to the above question what appears to be an important new conception regarding the significance of relativity mathematics with noteworthy results

I have abandoned altogether the quasi-geometrical interpretation with such hazy notions as parallel displacement in a curved space of *n* dimensions Instead, we construct an indeterminate vector field by means of Eddington's displacement rule, considered now as an association rule, and identify it at every point with the velocity a material particle might have if present there and then Vector lines in this field are necessarily the orbits of material particles under any physical conditions

We now construct an indeterminate tensor field, and by its means define the invariant magnitude of the elementary arc of these vector lines

Actual physical vector and tensor fields are necessarily determinate at every point, and these are defined as usual by applying the association rule round a closed loop This gives the usual symmetric and antisymmetric field tensors

When the antisymmetric field tensor vanishes the vector lines reduce to Einstein's so called geodesics The electric field is given by the antisymmetric tensor, and here the vector lines become mathematically equivalent to the known orbit equations Maxwell's first set of field laws are identically satisfied, and the set referring to electric charge and current are approximately true for small fields In strong fields in the neighbourhood of atomic nuclei the electron orbits reduce again to geodesics, independent of negligible radiation due to their acceleration, and Maxwell's second set of laws no longer hold This is obviously very strong support for our theory But further the introduction of field laws which reduce to Einstein's in the pure gravitation field appear to lead to a principle of selection among the orbits in nuclear regions

Before leaving England this summer I prepared a hurried account of the above theory intended for publication in the *Proceedings of the Royal Society* It unfortunately gave no explanation of the mathematics, which latter were faulty at one point A careful and complete revision has now proved the soundness of the theory, and publication will follow as quickly as possible WILLIAM BAND

Physics Department,
Yenching University,
Peking, Nov 26, 1929

Aucuba or Yellow Mosaic of the Tomato Plant Reaction of Infected Juice

IN the course of investigations into the physiology of virus diseases, it was observed that if the expressed juice from a tomato plant infected with aucuba mosaic disease be mixed with an aqueous colloidal solution of tomato chlorophyll, that is, the mixed green pigments extracted from fresh plant material by the method of Willstätter and Stoll from a healthy tomato plant, a marked action occurs under suitable conditions The most striking manifestation of this action is the development of a brown colour and, apparently, the destruction of a greater or lesser amount of the chlorophyll This browning action is either not shown or is shown to a very much smaller degree by the sap from a healthy plant

The reaction appears to show a marked sensitiveness to light and to be greatly accelerated by a light intensity of the order of 800 foot candles at a temperature of about 30° C, thus showing a certain parallel to the development of symptoms of mosaic disease in the living plant The reaction has not been found to occur to the same degree with a sample of infected sap which has been boiled for a few seconds, neither does it appear to be directly correlated with the oxidase or peroxidase content of the sap

Under the conditions of experiment, the browning has not been observed to take place to any marked degree with infected sap exposed to light in the absence of colloidal chlorophyll, although it is a matter of general observation that the sap from an infected plant either is brown or becomes brown on keeping Yet at the dilutions employed in the experiments referred to, this brown colour is scarcely perceptible and cannot account for the marked change on exposure to light, which is not shown by the sap in the absence of colloidal chlorophyll

These observations suggest that this reaction may provide a quick and quantitative means of studying *in vitro* the nature of the virus and its reactions, the examination of which up to the present has entailed prolonged inoculation experiments

Critical investigations are in hand with the view of obtaining a fuller understanding of this and cognate phenomena W F BEWLEY

The Vapour Density of Sodium

THERE is plenty of evidence in the literature to the effect that the vapour of sodium is monatomic Robitsch (*Ann Physik*, 38, 1027, 1912) determined the velocity of sound in the vapour at the boiling point and calculated the ratio of specific heats to be 1 68, and Taylor (*Phys Rev*, 28, 576, 1926) found no evidence of molecules at pressures of 10^{-8} mm Other evidence, which need not be considered here, tends to corroborate this opinion

With the discovery of the band spectra of diatomic molecules in the vapour of the alkali metals, it became necessary to consider the possibility of molecular association in the vapour state Carelli and Pringsheim (*Zeit f Physik*, 44, 643, 1927) calculated the heat of dissociation for the potassium molecule to be 0 61 volt A thermodynamic calculation indicates that potassium vapour will be associated to a very slight extent For sodium the best value of the heat of dissociation is that of Loomis (*Phys Rev*, 31, 323, 1928), $1\ 0 \pm 0\ 1$ volt, and thermodynamic calculations have been made which predict that there will be more molecules than atoms in the vapour of sodium near the boiling point Recently, Mr E G Walters, working with me in this laboratory, has re determined very carefully the vapour pressure and vapour density of sodium A complete account of the work will be published elsewhere, but it may be noted here that an apparent molecular weight of 25 was found for the saturated vapour at 706° C. By substituting the value of the equilibrium constant calculated from this result in the equation of Gibson and Heitler (*Zeit f Physik*, 49, 465, 1928) a value of about 0 75 volt is obtained for the heat of dissociation The agreement between this result and the value obtained by Loomis from band spectra cannot be considered entirely satisfactory without extending unduly the limits of probable error for one or both of the determinations

There is no reason to change the value for the entropy of monatomic sodium vapour calculated by Rodebush (*Proc Nat Acad*, 13, 185, 1927)

Native Policy in South Africa

I HAVE not read a full report of General Smuts's recent lecture at Oxford, but the note on p 816 of NATURE of Nov 23 suggests some questions

Is not the suggestion of segregation of the indigenous peoples of South Africa just about three hundred years too late ? The first colony of Europeans was established at the Cape of Good Hope in 1651 If the Africans were segregated, should they be denied the benefits of modern science, especially in health, hygiene, and transport ? In July there were articles in a Cape Town newspaper mentioning rates of infant mortality among the Africans, commonly 300 to 400 to the 1000 and rising in certain places to more than 500 to the 1000, while in the case of Europeans it was said to be less than 100 to the 1000 To this was attributed the stability of the ratio between Europeans and coloured in South Africa at the present time The full benefits of science can only follow the general spread of education

Is not the advantage of trying to maintain tribal distinctions a fallacy ? Have there not been discussions in favour of a United States of Europe ? How would tribal segregation have worked in Britain ? Think of the Scots pursuing their native customs north of the Tweed within a ringed fence, so to speak The breaking down of small tribal units and the synthesis now in progress must be beneficial in stemming strife and helping advancement This is occurring particularly under the influence of the great mining organisations, drawing labour from distant fields, and in turn calling on farmers for more food stuffs so that they also have to employ more labour

With the increasing ease of communication, which the African has been quick to adopt, the problem of the relations of the races must be solved on a basis much wider than that afforded by the limits of the Union of South Africa With this in view, the colonists in South Africa are no doubt already studying conditions in other parts of the Continent

The Stern-Gerlach Experiment with Active Nitrogen

IN view of the frequent use of these columns for the discussion of the problem of active nitrogen, it may be of interest to record the following observation A stream of nitrogen, activated by means of a condensed electrical discharge, was submitted to analysis by the Stern Gerlach method The active nitrogen, after passing through the non homogeneous magnetic field, struck a screen coated with silver nitrate, producing a brownish black trace thereon To be able to interpret the trace, the apparatus was calibrated by running hydrogen through it, so obtaining the trace for atomic hydrogen, the splitting of which corresponds to mg = ± 1 The trace obtained with active nitrogen gave mg = ± $\frac{1}{3}$ This value is characteristic of the $^2P_{\frac{1}{2}}$ state of the atom This observation thus gives a partial confirmation of the most recent views as to the nature of active nitrogen Thus Kaplan and Cario (*Zeits f Phys* , 58, 769 , 1929) suppose that the after glow in nitrogen is produced by the interaction of a metastable nitrogen molecule in the $^5\Sigma$ state with metastable atoms in the ^2P and ^2D states The chemical activity is ascribed to the metastable atoms The presence of ^2P metastable atoms and the fact that they are chemically active is established by the above observation

It is, however, of considerable interest to note that though the exposures were continued up to as much as 40 hours, no evidence of anything but the $^2P_{\frac{1}{2}}$ state was obtained, although the $^2P_{\frac{3}{2}}$ state, in particular, would have been expected as well, since the whole $^2P_2$ level is presumably metastable and the separation $^2P_{\frac{3}{2}} - {}^2P_{\frac{1}{2}}$ is only about 1 cm $^{-1}$, according to Compton and Boyce (*Phys Rev* , 33, 145 , 1929)

Full details will be published elsewhere

The Spectrum of Ionised Mercury Hydride

WHEN an arc discharge between mercury and tungsten electrodes in an atmosphere of hydrogen at 2 mm pressure takes place at such a low voltage (about 60 70 volts) that it cannot last more than a fraction of a second, the system of mercury hydride bands appears with remarkable intensity The set of bands occurring in the far ultra violet, which was first recorded by Jezewski (*Jour d Phys et le Radium*, Sept 1928), has now been found to be associated with ionised mercury hydride It can be definitely proved that it belongs to a $^1\Sigma \longrightarrow {}^1\Sigma$ system, the molecular constants being

	B_e	a	J_e	r_e	ω_e	x
Final state $^1\Sigma$	6 57	0 10	4 21 × 10 $^{-40}$	1 50 × 10 $^{-8}$	2016	0 020
Initial state $^1\Sigma$	5 8_8	0 3_8	4 7_0 × 10 $^{-40}$	1 6_0 × 10 $^{-8}$	164_7	0 04_9

Zero lines of the bands arranged in the n'/n'' table are

n' \ n''	1/2	3/2	5/2	7/2
1/2	44108	42168	40302	
3/2		43676	41810	40029
5/2				41398

Details will be given elsewhere

Width of Head and Pelvis in *Homo*

IN the *American Journal of Physical Anthropology*, April–June 1929, Prof John Cameron cites cranial measurements of numerous races, showing that the female skull is proportionately broader than that of the male The races measured are Bushman, Hottentot, various groups of negroes, Melanesian, Tasmanian, and Australian It occurred to me that the adaptive character of a broad pelvis might perhaps be correlated with an increased breadth of the head, the latter being then a secondary consequence of a sexual character of functional importance The breadth of the head (relative breadth) might again perhaps have other consequences

Prof Cameron writes me that the idea had not occurred to him, and his present opinion is that we have to do with a coincidence Yet the suggestion may be worth considering It would, of course, be very easy to obtain numerous head and pelvic measurements from living individuals, which would show any individual correlation that might exist

Possibly this whole matter has been discussed somewhere already Darwin remarks that some believe that the shape of the pelvis influences by pressure the shape of the head of the child

Weather Recurrences and Weather Cycles[1]

By Sir Richard Gregory

EVERY year the weather is in some sense abnormal, but the past twelve months have given us rather more than our fair share of extremes, beginning with the most severe winter since the famous frost of 1895, continuing through several long periods of drought to the rainiest November on record Unusual weather always leads to much discussion in the Press of the time honoured subject of weather cycles, and 1929 was no exception The point that the interval of thirty four years since 1895 was within a year of the famous Brückner cycle was not missed, and the spells of cool rainy weather which tempered the dryness of spring and summer have been widely hailed as manifestations of the ' Buchan cold spells '

Buchan, it may be recalled, was much interested in tracing annually recurrent spells of unexpected weather Thus a cold spell has been stated to occur regularly early in May, and has been associated with the so called ' ice saints ' Various explanations have been offered to account for this cold spell, the most popular being that in the course of the regular annual series of pressure changes which result from the increasing power of the sun in spring, an anticyclone develops over northern Europe at the time and causes a period of north easterly winds Another cold spell is supposed to occur in June, caused by the development of mon soon winds blowing into the interior of Europe Buchan in 1869 enumerated as many as nine such periods, to which he assigned the following dates

Cold Periods	*Warm Periods*
1 Feb 7–14	1 July 12–15
2 April 11–14	2 August 12–15
3 May 9–14	3 Dec 3–14
4 June 29–July 4	
5 Aug 6–11	
6 Nov 6–13	

These nine periods were deduced from observations in Scotland during a period of ten years in the middle of the nineteenth century In spite of this limitation, however, they have been assumed by many newspaper correspondents to be equally valid for the temperature of London in the twentieth century Such an assumption is quite unwarranted, and Buchan, if he were alive to day, would be the first to reject it No scientific evidence has ever been adduced that cold or warm periods have any tendency to occur in London on Buchan's dates

Alone among modern weather cycles, that of thirty-five years has a background of tradition, for it was described by Sir Francis Bacon before 1625 Many people are familiar with the passage from his essay " Of Vicissitudes of Things "

There is a toy, which I have heard, and I would not have it given over, but waited upon a little They say it is observed in the Low Countries (I know not in what part) that every five and thirty years the same kind and suit of years and weathers comes about again, as great frosts, great wet, great droughts, warm winters, summers with little heat, and the like, and they call it the prime , it is a thing I do the rather mention, because, computing backwards, I have found some concurrence

This weather cycle was rediscovered and carefully investigated by the late Dr Eduard Brückner, then professor of geography at the University of Bern, and it is now known generally as the Bruckner cycle His great work, " Klimaschwankungen seit 1700, nebst Bemerkungen uber die Klimaschwankungen der Diluvialzeit ", published in 1890, has become a classic for the patient collection and analysis of material from a great variety of sources He studied all the long records of rainfall, pressure, and temperature available at the time, and carried the record back into earlier centuries by utilising the variations of level in the Caspian Sea and other lakes in enclosed basins and in the great river systems of the world, the historic variations of ice conditions on the rivers of Europe, the dates of the wine harvest, and the frequency of severe winters

From all this material Bruckner deduced the existence of a long succession of cycles—series of generally warm and dry years alternating with series of generally cool and rainy years From A D 1020 to 1890 he found twenty five cycles, giving an average length of 34 8 years, but the individual cycles varied between twenty and fifty years With this in mind, we must not expect too much from the Bruckner cycle, for so great is this variation that only one cycle out of five comes within $2\frac{1}{2}$ years of the expected length When in addition one remembers that the amplitude of the variations is so small that in meteorological statistics the existence of the cycle can only be seen at all as the result of extensive smoothing, it becomes obvious that the Bruckner cycle is useless for the purpose of making long range forecasts of weather, and the interval of thirty four years between the cold winters of 1895 and 1929 takes its proper place as a mere coincidence

The true value of Brückner's work lies in a different direction Although the amount of rainfall may vary widely from one year to the next, the quantity of water which is stored up on the land areas, in the soil, in lakes, and in glaciers, varies far more slowly This stored water is not so closely related to the rainfall of the one preceding year as to the average rainfall of the ten preceding years, and if these ten years fall in the wet half of a Bruckner cycle, the quantity of stored water will be great Again, in the dull rainy countries of north west Europe, warm dry years are favourable for crops and vegetation, and on the whole the dry warm half of a Brückner cycle will yield better crops than the cool wet half, although there may be wide variations from one year to the next An agricultural community must take the bad years with the good, and trust to the surplus from a rich

[1] From the presidential address to the Royal Meteorological Society delivered on Jan 15

harvest to tide over a year of dearth, but at the end of the warm half of the cycle the community will be prosperous, while at the end of the cold half it will be poor. Hence waves of emigration and the movements of peoples are closely related to climatic cycles such as Bruckner's, which in this way may leave their mark on history. That, and not long range forecasting, is the rôle of the weather cycle.

In the rainfall of Great Britain the Bruckner cycle is far less important than one of fifty years. The authoritative pronouncement made by the Council of the Royal Meteorological Society in the matter of the supposed influence of broadcasting on weather contained a passage pointing out that groups of wet years in England have occurred about 1770, 1821 to 1830, 1871 to 1880 and 1922 to 1928, four recurrences at intervals of about fifty years, separated by groups of dry years in 1741–50, 1801–10, 1851–70 and 1891–1910, the inference being that the wet years since 1922 were due to some natural period of oscillation of the rainfall, and not at all to the relatively small electrical disturbance of the ether by human agencies.

Much attention has been given to the sunspot cycle in relation to weather, and the literature of this subject is enormous. Sunspots are a useful index of the activity of the sun, and they go through a not very regular cycle with an average length of 11·125 years. Taking account of the change of polarity discovered by Dr. G. E. Hale, it is more accurate to say that sunspots go through a double cycle of 22·25 years. In terrestrial phenomena, these changes of solar activity are accompanied or closely followed by fluctuations in the elements of terrestrial magnetism and by variations in the frequency of auroræ. In matters of weather, a connexion with temperature was first suspected by Riccioli so early as 1651, and was clearly demonstrated, for tropical regions, by W. Köppen in 1873. A fairly close relationship has been traced by Dr. C. E. P. Brooks between the sunspot number and the rainfall in certain parts of equatorial Africa, especially the plateau of Lake Victoria, and the eleven-year cycle in the level of this lake, which rises and falls with the rise and fall of solar activity. This is one of the most striking illustrations of the connexion between solar and terrestrial phenomena, as may be seen from the accompanying diagram (Fig. 1), reproduced from Dr. Brooks's memoir.[1] A similar relationship is found in Lake Albert and farther south in Lake Nyasa, though in the latter it is somewhat obscured by the large annual variation in the level of the lake and by other factors.

In Great Britain the eleven-year sunspot cycle, like the Brückner cycle, is of little importance.

Although we are undoubtedly governed in the long run by solar influences, these find their way from equatorial to temperate latitudes by many and sometimes devious routes, winds, ocean currents, and so forth, so that their unity becomes lost and they appear as an irregular series of changes following no apparent law. For example, it was found by Dr. G. Hellmann that the rainfall of Europe has two maxima and two minima in each sunspot period, and he explained this as due to the combination of two causes, the direct effect of the solar variations on the weather of Europe and the indirect effect due to changes at the equator extending their effect northwards. In 1928, Dr. Brooks, after an examination of the relation between sunspots and pressure, both at individual stations and the distribution of pressure as a whole, concluded "that at present the variations of sunspots in the eleven year cycle cannot be taken into account in predicting quarterly mean deviations of pressure in the eastern North Atlantic or western Europe".

Mean Monthly Readings of the Lake Gauge on Lake Victoria & Monthly Sunspot Numbers 1896 1927

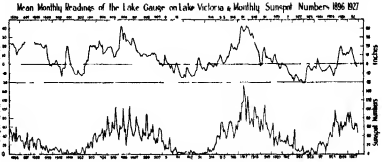

FIG. 1.

The suggestion has been made, notably by Defant, that there is a natural period of about 3½ years in the oscillation of the earth's atmosphere, which requires to be set going by some vigorous impulse; Defant found such an impulse in a violently explosive volcanic eruption. Others, notably Sir Norman and W. J. S. Lockyer, have found in them yet another manifestation of solar influence, such for example as is shown in the distribution of solar prominences. In some parts of the world, notably the East Indies, these periodicities of a few years are of undoubted value in forecasting the general rainfall some months ahead; in Great Britain they have at times reached a spectacular development, but always, just when they seemed to have established themselves thoroughly, they changed the length of their phase, or otherwise proved themselves unstable as water.

As the result of a great amount of research into a single definite problem, Mr. J. Baxendell was able to show in 1925 that we possess more exact information about a 5·1 year periodicity in British weather than about any similar phenomenon. The story of this period, as unfolded by the late Carle Salter and J. Glasspoole, begins in 1868. For fifteen years, up to 1882, each fifth year (1872, 1877, 1882) was very much wetter than any

[1] Air Ministry, Meteorological Office. *Geophysical Memoirs* No. 20 (London: H.M. Stationery Office, 1923.)

of the remaining twelve Then this series broke down, but from 1889 until 1909 there was a most remarkable sequence in which every third year was abnormally wet The years 1891, 1894, 1897, 1900, 1903, 1906, and 1909 were all wetter than the average, of the remaining eighteen, one was exactly normal and the others were all dry After 1909, however, the sequence changed to an almost equally remarkable two-year oscillation From 1910 until 1922 the even years were all much wetter than the average, while the odd years were all dry, with the sole exception of 1915, and even that year was drier than either 1914 or 1916 After 1922 this two-year sequence broke down, and now we seem to have returned temporarily to the three year type

Progress in Naval Engineering.

By Eng Capt EDGAR C SMITH, O B E, R N

THOUGH surpassed in length by the presidential address of Sir William White to the Institution of Civil Engineers in 1903, the Thomas Lowe Gray lecture delivered to the Institution of Mechanical Engineers on Jan 3 by Engr Vice-Admiral R W Skelton, Engineer-in Chief of the Fleet, on progress in marine engineering, bears comparison with it as an authoritative official review of an important subject While Sir William White traced the evolution of mercantile and naval vessels, Admiral Skelton confined himself to the progress in marine machinery, and his lecture is probably the most extensive survey so far written His predecessors, Admirals Durston, Oram, Goodwin, and Dixon, in their addresses and papers to the technical institutions, have all dealt with various aspects of naval and marine engineering, and were the series of contributions collected in a single volume it would go far towards filling one of the many gaps in the literature of engineering history Such a volume should at least be available in every man-of-war and every school where marine engineering is studied

Though not mentioned by Admiral Skelton, the first suggestion for a steam driven war vessel was made to the Admiralty by Earl Stanhope For him the authorities built the 'ambinavigator-ship', called the *Kent*, and so sure did Stanhope feel that he was on the high road to success that in June 1794 he signed a bond with a penalty of £9000 "to indemnify the public in case the said ship should not answer the purpose of Government" The inventor did not merely intend to produce a result, but he hoped "to establish every part of the subject on clear and irrefragable proofs, and to ascertain demonstratively what is the best possible plan" The experiments failed and the matter was dropped, without Stanhope, however, being kept to his bond Twenty years elapsed before the Navy had anything more to do with steam, and then the suggestion came from Sir Joseph Banks Capt Tuckey was preparing for surveying the river Congo in the *Congo* Why not fit her with a steam engine? Constructed by the greatest engineering firm in the world, Boulton and Watt, the engine was delivered, put into the ship, taken out again and set up in Chatham dockyard So heavy was the machinery that the *Congo* would have foundered in any sort of sea, and Capt Tuckey therefore wisely decided to stick to sails Five or six years passed and with the building of the *Comet*, *Lightning*, and other small steam craft began a series of revolutionary changes in everything pertaining to warships

It cannot be said that early naval requirements made any severe call on the engine constructors of the day Fulton had launched the *Clermont* in 1807, Bell the *Comet* in 1812, and steam vessels were proving their worth on every ocean But few realised the value of steam in war vessels, and there was no more stubborn opponent of steam than Capt Sir William Symonds, the Surveyor of the Navy The Russian War of the 'fifties, however, showed the futility of any longer trusting exclusively to the wind, and on April 22, 1854, the officers and men of the Black Sea fleet saw for the last time a British frigate in action under sail By that time, slow as progress had been, the paddle had given place to the screw, the flue boiler to the tubular boiler, engines were becoming more powerful, and many of the younger generation of naval officers, who knew more about railways and electric telegraphs than of the fighting of the Napoleonic wars, had eagerly taken up the study of engineering

Admiral Skelton gave much interesting information regarding those early days, and then proceeded to review matters which are more familiar to our ears He was unable to read the whole of the lecture, which, however, will be published in full by the Institution of Mechanical Engineers When available it will be seen to contain as an appendix a tabulated statement of some forty ships, from the fine paddle frigate *Terrible* of 1842 to the cruiser *Berwick* of 1925 It is a happily chosen list, and the progress of naval engineering could well be traced by a study of a ship from each decade The fourth ship in the list is the *Agamemnon* of 1851 Other wooden two deckers had been altered to receive the screw, but the *Agamemnon* was the first of her class to be designed as a screw ship Her engine by Penn would reflect credit on any shop to day It was a simple expansion horizontal engine with two cylinders fitted with trunk pistons something like the pistons found in a motor car The square tubular boilers generated steam at 20 lb pressure, and the engine developed 2268 h p The machinery weighed 320 lb per h p, cost £15 9*s* per h p, and consumed 5 lb of coal per h p per hour Compare this with the *Berwick*, the machinery of which, developing 80,000 h p, weighs only 45 5 lb per h p, cost but £5 6 per h p, and consumes only 0 89 lb of oil per h p per hour

Under the command of Capt W. R Mends the

Agamemnon was sent to the Mediterranean under sail, took part in the bombardment of Sevastopol in October 1854, and the following month successfully rode out the great storm which worked havoc in the fleet Mends, who had studied the steam engine, had an anxious time, but after the storm wrote to his wife "I soon had a third anchor down and kept the engine going to ease the cables, which, thanks to James Watt, enabled the good ship *Agamemnon* to ride easily"

The twenty pounds pressure of the *Agamemnon* represented the general practice at sea, marine engineers being timid regarding the use, and ignorant of the value, of high pressure steam A step forward was made in the *Constance* of 1860, which had John Elder's compound engines working with 30 lb pressure No one would want to be shipmates with her engines to day, for they were most difficult to handle and maintain Elder, however, was the leading advocate of the compound engine, around which a tremendous controversy raged, but which by the 'seventies was specified for all naval vessels The early twin screw ironclad *Dreadnought* of 1872, for example, had vertical compound engines of 8207 h p working at 60 lb pressure, and her coal consumption was but 2 32 lb as against the 5 lb of the *Agamemnon* of twenty years earlier It was about this time that engineers began to understand something of the work of Joule and his contemporaries on the mechanical equivalent of heat In the Royal School of Naval Architecture and Marine Engineering, too, naval engineers were trained under some of the finest teachers of the day, among whom was Prof Unwin, who is happily still with us, a veteran of more than ninety years

From the 'seventies onward change succeeded change The compound engine of Elder gave way to the triple expansion engine of Kirk, square boilers were replaced by cylindrical boilers, steam invaded every part of the warship, and the chief engineer of an ironclad became the head of a staff upon whose efforts mainly depended the efficiency of the ship as a fighting machine Nineteenth century mechanical engineering could show nothing finer than the great triple expansion reciprocating engines such as were found in the Atlantic liners, and in such cruisers as the *Drake* and *Good Hope*, each set of the engines of which developed 15,000 h p They were constructed when the demands of the naval authorities for greater speeds were incessant and when the attempts to comply with those demands brought a whole host of difficulties There were troubles with boilers, with condensers, with bearings, thrusts, pistons, pumps, auxiliaries, packings, pipes, joints, glands, and valves Engine designers did their utmost to overcome the defects, but it was, as Admiral Skelton said, upon the engineering branch of the Navy that the brunt of the work fell Yet it was also in the arduous times of the 'eighties and 'nineties that naval engineers gained the experience which proved of such vital importance to the Empire during the War

Of the forty-four ships in the Table, fifteen are turbine driven The list begins with the *Amethyst* and *Dreadnought*, and includes such well known vessels as the *Glasgow*, *Lion*, *Hood*, and *Nelson* No one is likely to disagree with the remark that the successful application of the steam turbine afloat was largely due to the soundness of the conceptions of the inventor and his thorough exploratory work in connexion with the marine application Had all innovations into the engine rooms of warships been accompanied by as few setbacks as was the turbine, naval engineering recollections would be far less interesting than they are The importance of the change from reciprocating engine to steam turbine is comparable with the importance of the change from paddle to screw, and so far as can be seen at present the turbine appears likely to hold its own for warship propulsion for a long time

The introduction of the water tube boiler came before the turbine, but the change from coal burning to oil burning has taken place in the last twenty years, and improvements in the stokehold have been as great as those in the engine room The results can be seen by comparing the *Dreadnought* of 1905, the *Hood* of 1916, and the *Berwick* of 1925 The weight of machinery per horse power, has diminished in the ratio 184 84 45 5, the square feet of floor space required per horse power in the ratio 0 45 0 136 0 118, while the cost of the machinery per horse power of the three ships was £13 9, £9 6, and £5 6 respectively There is necessarily an ultimate limit in the possible reduction in weight and size and fuel consumption, and some writers forty years ago thought they were within measurable distance of it, but the age of improvement is still with us and engineers are still striving, like Earl Stanhope, to determine "what is the best possible plan"

Obituary

MAJOR P G CRAIGIE, C B

MAJOR PATRICK GEORGE CRAIGIE, the leading authority for some half a century on agricultural statistics, died on Jan 10 at the age of eighty six years Educated at Perth, the University of Edinburgh, and St Catharine's College, Cambridge, he acted as secretary to the Local Taxation Committee from 1871 until 1890 and of the Central Chamber of Agriculture from 1879 until 1890 He was twice employed by Royal Commissions to report on the markets of Paris and Brussels, and on the agricultural schools of France Shortly thereafter, on the formation of the new Board of Agriculture, he was selected as the obvious man for the directorship of the Statistics, Intelligence, and Education Branch, a post which he held from 1890 until 1897, when he became Assistant Secretary, retiring in 1906 Craigie was the founder of modern British agricultural statistics, and their value is largely due to his enthusiasm and initiative

In spite of the heavy pressure of official duties, Craigie found time for much other work He became a fellow of the Royal Statistical Society in 1874, acted as one of the honorary secretaries from 1887 until 1902, and during 1902–4 occupied the presidential chair To the *Journal* of the Society he contributed a long series of papers, amongst others "The Cost of English Local Government", 1877, "Ten Years' Statistics of British Agriculture", 1880, "Statistics of Agricultural Production", 1883, "The Size and Distribution of Agricultural Holdings in England and Abroad", 1887, "The English Poor Rate, Some Recent Statistics of its Administration and Pressure", 1888, and his presidential addresses of 1902 and 1903

He was president of Section F (Economic Science and Statistics) of the British Association in 1900, and of the Sub-Section for Agriculture at the Winnipeg meeting of 1909 In the work of the International Statistical Institute he took a very active part, attending the meetings for many years as official British delegate, for a short period he was secretary-general and later treasurer The value of his services to statistical science, especially in relation to agricultural statistics, was recognised by the award to him, in 1908, of the Royal Statistical Society's Guy Medal in gold

A most kindly and genial man, "a redoubtable champion of agricultural interests, a pioneer of agricultural progress, a successful administrator during the seventeen years that he laboured at the Board of Agriculture, and probably the most loved of all officials who ever entered its portals", as Lord Bledisloe states in the *Times*, Major Craigie was greatly missed by many friends in London when, after his retirement, increasing years and infirmity kept him at his home in the west of England

HERR CARL SCHOCH

CARL SCHOCH died on Nov 19, 1929, at the age of fifty six years His death deprives astronomy of a very active student of ancient astronomical records, who has contributed to the improvement of chronology by the identification of several eclipses and other astronomical phenomena for example, his identification of the lunar eclipse observed at Ur in B C 2283 is used by Prof S Langdon in his recently published chronological tables His astronomical studies have been going on since 1900 He made a new determination of the *arcus visionis*, or distance from the sun at which different objects could be detected at their heliacal rising He also studied the rules that were followed in Babylonia, etc, as regards the insertion of intercalary months, a matter of great importance in the identification of recorded phenomena He worked for a time at Oxford, assisting Dr J K Fotheringham in the studies that he made, in conjunction with Prof Langdon, on the Venus tablets of Ammizaduga That work contains, as an appendix, tables of the moon and planets prepared by Schoch, which extend back to B C 3507 The secular accelerations play an important part in deducing positions at such remote dates Schoch made an independent study of these, reaching results nearly identical with those deduced by Dr Fotheringham In 1928 he published a revision of Oppolzer's 'Syzygientafeln', which greatly increased their accuracy Many of his astronomical conclusions have been referred to from time to time in our columns

---

WE regret to announce the following deaths

Prof H L Callendar, F R S, professor of physics in the Imperial College of Science and Technology, on Jan 21, aged sixty six years

Prof Ludwig Claisen, of Kiel and Berlin, well known for his work in organic chemistry, on Jan 5, aged seventy eight years

Dr Harry Taylor Marshall, since 1908 Walter Reed professor of pathology and bacteriology in the University of Virginia, who was president in 1922 of the American Association of Pathology and Bacteriology, aged fifty four years

Mr F P Ramsey, lecturer in mathematics in the University of Cambridge, on Jan 19, aged twenty six years

Sir George Thane, professor of anatomy at University College, London, from 1877 until 1919, on Jan 14, aged seventy nine years

Dr Victor C Vaughan, formerly dean of the Medical School of the University of Michigan, member of the National Academy of Sciences and past president of the American Medical Association, known for his work on bacterial toxins, on Nov 21, aged seventy eight years

News and Views

CONGRATULATIONS from many in the world of science will be accorded in the coming week to Sir Robert Elliott Cooper, K C B, a past president of the Institution of Civil Engineers, and among the oldest of English engineers, who celebrates on Jan 29 his eighty fifth birthday, also to Dr Henry O Forbes, anthropologist, botanist, and pioneer traveller in many lands, who is seventy nine years of age on Jan 30 The former is a Yorkshireman, and he was educated at Leeds Grammar School Entering the firm of Messrs John Fraser, of Leeds, he left them in 1876 to engage in professional work in London, gaining a high reputation as a civil engineer Whilst president of the Institution of Civil Engineers, Sir Robert was responsible (1912) for an address which embodied a comprehensive and detailed survey of engineering projects completed or in hand in the overseas Dominions, Crown Colonies, and other parts of the British Empire Then, during the War, he was chairman of the War Office Committee of the Institution, perhaps the most signal as well as final expression of consistent and devoted public service We may add, however, to the record, his active interest in the advancement of the National Physical Laboratory There is a portrait of Sir Robert hanging in the apartments of the Institution of Civil Engineers

DR HENRY O FORBES was born at Aberdeen, and educated there at its Grammar School, graduating afterwards at the university, and at Edinburgh Exploratory work in little known regions of the world became a fascinating and compelling outlet for his activities, and this very early in life More than fifty years ago he was exploring and collecting in Java, Sumatra, and Timor The Royal Geographical Society allotted him the Gill Memorial Award in 1893 for explorations and observations in New Guinea, the Malay Archipelago, and Chatham Islands In 1890–93 he was director of the Canterbury Museum, New Zealand From 1894 to 1911 he was Director of Museums to the Corporation of Liverpool The British Association found a zealous coadjutor in Dr Forbes, whether as a member of council, lecturer, or in a consultative capacity Apart from book writing Dr Forbes is the author of various memoirs, detailed in the Royal Society's "Catalogue of Scientific Papers", among which is "New Guinea attempted Ascent of Mount Owen Stanley" The Government of Peru commissioned him in 1911–13 to report upon the birds of the Guano Islands Dr Forbes is an honorary LL D of Aberdeen

AT the annual general meeting of the Royal Meteorological Society on Jan 15, the Symons Memorial Medal for distinguished work in meteorology was presented to Dr G C Simpson Dr Simpson received his academic training at the University of Manchester, where he became interested in meteorology, and especially in atmospheric electricity A research studentship enabled him to carry out an investigation into the ionisation of the air in high latitudes, at Karasjok in Lapland On his return to England, he was for a short time attached to the Meteorological Office, after which he took up an appointment as reader in meteorology at his old university, where he conducted an important series of kite ascents at the University Observatory on Glossop Moor In 1906 he joined the Indian Meteorological Department, and in 1910–12 he was granted leave of absence to take part in Capt Scott's second South Polar Expedition His two volumes on "Meteorology", which form part of the results of that expedition, added greatly to our knowledge of the atmosphere in the Antarctic

AFTER a period of War service, in 1920 Dr Simpson was appointed a member of the Nile Irrigation Commission, and spent six months studying conditions in Egypt In September of that year he became Director of the British Meteorological Office Throughout his career he has maintained his interest in research, especially in atmospheric electricity, where his fundamental investigations into the origin of the electric charges in thunderstorms by the breaking of rain drops were followed by critical studies of the mechanism of thunderstorms and the nature of lightning In recent years he has become interested in the problems of radiation, and has shown how cycles of solar radiation are able to account in a remarkable way for the phenomena of the Quaternary Ice Age, including the succession of glacial and interglacial periods and the increased rainfall in unglaciated regions

REFERRING to our remarks last week (p 97) on Syon House and estate at Isleworth, where it is proposed to place a sewage disposal works, a correspondent reminds us that during the life of Sir Henry Percy, ninth Earl of Northumberland Syon House was frequently the home of some of the early English men of science Born in 1564, Earl Percy served in the Low Countries, fitted out a ship for fighting against the Spanish Armada and was a staunch supporter of the Stuarts Though a Protestant, he was, however, tried for treason after the Gunpowder Plot and spent many years in the Tower His love of astrology and scientific experiments caused him to be called 'The Wizard Earl" The English mathematician Nathaniel Torporley (1564–1632), the friend of Vieta, Thomas Allen (1542–1632), who wrote an exposition of the works of Ptolemy, and Thomas Harriot (1560–1621), "the universal philosopher", a correspondent of Kepler, and the first in England to observe sunspots, were all patronised by the Earl, and Harriot for many years lived in the old Syon House After the Earl had been committed to the Tower, Walter Warner, Thomas Hughes, and Harriot, like Raleigh, often kept him company there and were known as his "three magi" Torporley bequeathed to Syon House all his books, maps, and instruments

THE Institute of Industrial Administration, to which reference is made in our leading article this week, has laid down a definite course of instruction and established an examination for a diploma in industrial administration This is a step towards making industrial management a 'profession', and it should do something to mediate between the equally excusable but equally unsatisfactory opposite suppositions that educated men, on one hand, are incompetent in industry and, on the other, that the hand to mouth methods of the uneducated practical man are efficient Clearly, we can combine practical experience of the workshop with a wider knowledge of psychology, economics, and government than our old fashioned managers had A more fundamental issue, however, has still to be faced, if we are in earnest about rationalisation, for the directors themselves in certain enterprises seem to be incompetent It is not good sense, for example, to have as directors in a chemical trade men who know nothing at all of chemistry, or to have architects who know nothing about the chemistry of the new or the old building materials Even if shop organisers and employment managers are competent, they will be helpless so long as the directors in control of policy do not understand the *ABC* of the sciences which they might use The president of the Institute of Industrial Administration is Mr A S Comyns Carr, and its address 47 51 King William Street, London, E C 4

THE report of the twentieth meeting of the Indian Central Cotton Committee, held on Nov 11 last at the Institute of Plant Industry, Indore, contains several matters of scientific significance The interest taken by leading industrialists in India in the scientific development of agriculture is exemplary The work of the Institute of Plant Industry has impressed Indian industrial leaders and ministers so much that large

sums of money have been given to develop the new variety of Malvi cotton which the Institute has selected, and to put into practice the suggestions made by the Institute for the improvement of agriculture generally This interest may be illustrated by the following extract from the report of the speech of the Prime Minister of the Holkar Government at the meeting "We must naturally proceed slowly and only take up improvements and new ideas after they have been carefully considered and also carefully tested by scientific investigators whose experience, performance, and standing carry weight" This statement shows that the important part which science plays in industrial development is thoroughly understood by some Indian leaders

WE find later in the report that the Committee's plans are widening to include the cotton manufacturing industry A few years ago the Committee built the Cotton Technological Laboratory at Matunga, Bombay The laboratory has a large and capable scientific staff and is well equipped with modern apparatus and a complete spinning plant The standardisation of Indian cottons was its primary function, but its recent bulletins have included investigations in the technology of cotton spinning which are noteworthy contributions to this branch of applied science Again, Indian industrial interest has been stimulated by the work of a scientific laboratory with the result that it was decided at the Indore meeting to extend the work to meet the requirements of the mill industry and the cotton trade generally This step now brings within the control of the Indian Central Cotton Committee the scientific development of all branches of the Indian cotton industry, from the selection and raising of the crop to the production of the finished article The Committee is to be congratulated on its foresight, and all scientific men will appreciate its efforts to apply scientific control to the development of the Indian cotton industry

THE three leading events in the history of the steam railway were the opening of the Stockton and Darlington railway on Sept 27, 1825, the famous Rainhill locomotive trials of October 1829, and the inauguration of the Liverpool and Manchester Railway on Sept 15, 1830 If the first of these events showed the practicability of passenger transport by railway, the second demonstrated the superiority of the steam locomotive over all other methods of traction, while the world's railway system may be said to have had its birth with the completion of the Liverpool and Manchester Railway, when on Sept 15, 1830, a train composed of eight locomotives and twenty eight carriages, containing some six hundred persons, proceeded along the line The following day, Sept 16, regular trains were run, and by the end of the week there was a daily service of six trains in each direction To commemorate this epoch making event, arrangements are being made to hold a pageant and an exhibition at Liverpool on Sept 14–21 next, when it is hoped to bring together a collection of books, pictures, models, locomotives, etc, illustrating the progress of railroad transport An executive committee has been formed representing both civic and railway interests, with headquarters in the Royal Liver Buildings, Liverpool, and an appeal has been issued for information from anyone interested in the development of railways who can supply particulars of historic exhibits

IT is announced that the Latinisation of the Russian alphabet is a probable development of the near future A Moscow commission has studied the technical details and has almost completed its investigations Immediately after the Revolution, the Russian alphabet was simplified by discarding one or two superfluous or little used letters There are still more than thirty letters in the Cyrillic alphabet as against twenty six in the Latin, so that any change will necessitate either the elimination of further letters or, which is most likely, the introduction of diacritical marks to express sounds for which there is no precise equivalent among the simple Latin letters It will be recalled that some years ago Prof Bohuslav Brauner advocated this (the Czech) mode of transcription from Cyrillic to Latin in NATURE (April 29, 1922, vol 109, p 552) on the grounds of simplicity and faithfulness to the original The following changes involve the introduction of diacritical marks over consonants

ш becomes š pronounced as *sh* in she
щ ,, šč ,, *shch*
ч ,, č ,, *ch* in church

The letter ц, if transcribed to *c*, must be pronounced like *ts* in its The change from the Russian to the Latin alphabet is to be welcomed, for not only will it be easier for educated Russians to learn western European languages, but it will also facilitate the acquiring of a knowledge of Russian by others

THE fifth International Botanical Congress is to be held at Cambridge on Aug 16–23 next The sequence of congresses in this series is Paris 1900, Vienna 1905, Brussels 1910, the 1915 Congress was to have been held in London, and arrangements were well in hand when War broke out After active hostilities had ceased an international congress was formally discussed on several occasions, but it was considered that more would be lost than gained unless all nations could take part Eventually, American botanists offered to hold a congress at Ithaca in 1926 if British botanists would waive their title to precedence The conference was held as the International Congress of Plant Sciences (Fourth International Botanical Congress) The 1930 Congress returns to the old terminology

A PRELIMINARY programme of the Cambridge meeting has been circulated giving a summary of information for the benefit of foreign visitors and also the names of presidents, vice-presidents, recorders, secretaries, etc, of the Congress as well as of the eight sections bacteriology, phytogeography and ecology, genetics and cytology, morphology, mycology and plant pathology, plant physiology, palæobotany, taxonomy and nomenclature The programme gives expression to the general opinion that more benefit is likely to arise from discussions than from individual communications, and the sectional programmes give the titles of the proposed discussions, usually with a list

of those who have promised to speak Any person interested in botany may become a member of the Congress on payment of the subscription of £1, which should be sent to the honorary treasurer, Dr A B Rendle, British Museum (Natural History), S W 7, by April 1 next

IT is seldom that we refer to the weaknesses of popular natural history articles, but the *Nineteenth Century* for January published one on "The Badger and its Reputation", which moves us to protest In this ten page article, the first six pages, containing much general denunciation of the ignorance and inaccuracy of naturalists, scarcely mention the badger The remaining four, amongst otherwise simple information, state that "the badger appears to possess senses entirely unknown to science", that "unlike any other animal, he seems to be able to exist almost entirely without air", that the hedgehog, "another insectivorous creature", is in most of his ways a badger in miniature The Nature loving public deserves something better than this

INDEED, the same number of the *Nineteenth Century* includes another Nature article of very different stamp In "The Origin of Right", A Wyatt Tilby records the results of much observation and consideration of the curious fact that right sidedness is a widely spread feature in the animal world Right handedness is predominant amongst men, and more start off on the right foot than on the left Cats are said to be right footed, so are civets, genets, giraffes, and camels Even molluscs have usually right twisted shells On the other hand, wolves and deer are left footed, whereas dogs, horses, and antelopes start off indifferently with the right or left foot The author does not say under what conditions or from how many observations these results were obtained, but one of his conclusions is that practically every animal that grips, climbs, or hunts uses the right approach or the right foot first in preference to the left He also endeavours in a series of interesting paragraphs to trace the causes which may have contributed to the formation of the 'right' habit and its survival in different categories of animals Our impression is that the subject is still very hazy

IN an address in honour of Mr Edison at the dedication of the Edison Institute of Technology, the gift of Mr Ford, President Hoover paid a notable tribute to men of science and their work "Our scientists and inventors are amongst our most priceless national possessions There is no sum that the world could not afford to pay these men who have that originality of mind, that devotion and industry to carry scientific thought forward in steps and strides until it spreads to the comfort of every home, not by the profits of all the banks in the world can we measure the contribution which these men make to our progress And they are the least interested in the monetary results Their satisfactions are in their accomplishment—in the contribution of some atom of knowledge which will become part of the great mechanism of progress Their discoveries are not the material for headlines Their names are usually known but to a few But the nation owes them a great honour and is proud to demonstrate through Mr Edison to day that their efforts are not unappreciated The country can well pay its tribute to the men of this genius by expanding the facilities for their labours The nation to day needs more support for research It needs still more laboratories" The address, which was delivered at Dearborn, Michigan, on Oct 21 last, is a fine example of pointed eloquence It is published in the *Scientific Monthly* for December

LEONARDO DA VINCI, whether considered as artist, sculptor, architect, engineer, inventor, biologist, or physicist, is such an outstanding figure of his time, and the works he executed and the manuscripts he left are of such intrinsic value, that he is bound to attract the attention of succeeding generations of students His versatility was ably brought out by Mr E McCurdy, in his lecture to the Royal Institution, reported in NATURE, May 6 and 13, 1920 Dr I Hart has treated of his mechanical investigations, and a list of his contributions to pure and applied science is contained in Prof Usher's "History of Mechanical Inventions" It was G B Venturi (1746–1822) who first directed attention to the significance of Leonardo's scientific work, and much has been written since A further contribution to the study of his views is contained in the first number for 1930 of *Scientia*, in which R Marcolongo, of the University of Naples, deals with "The Dynamics of Leonardo da Vinci" The article is published in Italian After a brief review of the writings of the Greeks and of some little known work of the fourteenth century, the writer, using the manuscripts of Leonardo, quotes his statements regarding weight, force, gravity, the laws of motion, and motion down a plane and in the arc of a circle, showing him to be a precursor of Galileo and Newton Leonardo was essentially a reformer and belonged to that age which produced Erasmus, Copernicus, Durer, Luther, Agricola, and Paracelsus

RAPID progress is being made in constructing the Bavarian Zugspitze Mountain Railway, as it is desired to open service on this line, with the exception of the aerial ropeway to the top, before March This date was chosen so that visitors to the famous Passion play at Oberammergau may have an opportunity of seeing the beautiful mountain scenery traversed by the railway In many respects it will be like the Jungfrau railway According to *A E G Progress* for December last, the final station will be on the summit, 9750 feet above sea level The first section of the line, 4 7 miles in length, will be run by ordinary adhesion locomotives, the maximum gradient being only 3 5 per cent The next section, 6 9 miles long, will be a rack railway, and the final aerial ropeway to the summit will be 0 37 mile long The maximum gradient on the rack railway is 25 per cent, and on the aerial ropeway 68 per cent The Schneeferner Haus is a hotel at an altitude of 8750 feet, which has been planned by the railway company so as to provide plain accommodation for the ordinary traveller and luxurious rooms for the wealthy When the final section leading to the summit is com-

pleted next summer, the total time taken by the trains from the low-level station at Garmisch Partenkirchen (altitude 2300 feet) to the summit will be one hour and fifty minutes, three minutes only being required for the aerial ropeway The electric energy required for the railway is supplied by three phase current from the Isar power station At the sub station it is converted into direct current at 1500 volts by glass bulb rectifiers At full load these will work at 1650 volts These rectifiers are novel in design and are being used in practice for the first time

THE December number of the *Journal of Scientific Instruments* gives many illustrations of the uses to which science can be put by means of robust instruments which almost any one can safely use An apparatus is described by means of which the change in the moisture content of small quantities of a powder can be readily and accurately determined by means of a torsion balance Curves are shown and can be quickly found giving the rate at which moisture is absorbed by industrial products like flour, starch, and tobacco Results obtained in this way are of great use in commerce The General Electric Co describes apparatus which, when perfected, will measure the colour, temperature, and luminous output of an incandescent lamp Photoelectric cells are used, and it is satisfactory to find that definite results can be obtained An ingenious method of measuring the internal diameters of transparent tubes, perfected at the National Physical Laboratory, is described The two-ball method described enables the diameter to be easily measured in any given axial plane Thus the ellipticity as well as the variation in size of the cross section can be determined The method can also be applied to opaque tubes Steel balls the diameters of which increase by very small steps from 1/16 in to 1 in are readily obtainable The method can be applied to tubes the bore of which is only about three millimetres A description is given of an instrument for measuring the thickness of compressible solids, for example, fabrics, over a very wide range of pressures This instrument should be of use for the woollen and worsted industries The use of elinvar instead of steel in the spring of the Galitzin vertical seismograph at Kew has enabled the temperature coefficient of elinvar to be determined It is only one tenth that of the steel spring A clear description is given of the Moll recording microphotometer for use in the investigation of photographed spectra This journal contains much interesting information which should prove of value to all engaged in industrial research

AT the annual general meeting of the Royal Microscopical Society, which was held on Wednesday, Jan 15, the report of the council was adopted, and the following were elected officers and new members of council for the ensuing year —*President* Prof R Ruggles Gates, *Treasurer* Mr Cyril F Hill, *Secretaries* Mr J E Barnard and Dr Clarence Tierney, *New Members of Council* Prof W A F Balfour Browne, Mr E W Bowell and Prof Doris L Mackinnon, *Librarian* Dr Clarence Tierney, *Curator of Instruments* Mr W E Watson Baker, *Curator of Slides* Mr E J Sheppard The council's report stated that the Society continues to play an increasingly important part in the application of science to British industries In the absence of the president, Mr J E Barnard, through illness, the chairman announced that the presidential address on "Resolution and Visibility in Medical Microscopy" would be delivered at the Society's meeting in March A paper was read by Dr W E Cooke on asbestosis, in which he described the history and incidence of this disease amongst those engaged in the industry, and its identification A valuable contribution to our knowledge was also submitted by Mr T D Hamilton in a paper on "The Preparation of Thin Microscope Sections of Whole Organs by the Paraffin Method"

THE inaugural meeting of the eighty third session of the Pontifical Academy of Sciences, held at Rome on Dec 29 last, was honoured by the presence of His Holiness Pope Pius XI, who was received by the president, Prof P Giuseppe Gianfranceschi, the secretary, Prof Pietro De Sanctis, and the vice secretary, Prof Giuseppe Martinelli A number of papers were communicated, including the following A Belluigi rules for obtaining a good thermal yield with Schmidt magnetic variometers, P Luigioni second contribution to the knowledge of the entomological fauna of the National Park of Abruzzo a new species of Chrysochloa, A Anile new researches on the etiology of scarlatina, A Neviani lower marine organisms of supposed vegetable character, V Zanon diatoms of the Permian and Carboniferous, G Franchini experimental reproduction of leprosy in the ape, P Humbert Bessel functions of the third order, S Ranzi physiology of the embryo of cephalopods, Pasquini new experimental results on the grafting of the eye in Axolotl, C Gorini bacterial chymases, G De Angelis d'Ossat geology and the Roman catacombs One half of the prize of 10,000 lire offered for dissertations on the quantum theory has been awarded to Prof Wataghin, the other half being divided equally between Profs Straneo and Carrelli

THE ninety eighth annual meeting of the British Medical Association will be held at Winnipeg, under the presidency of Prof W Harvey Smith, professor of ophthalmology, Manitoba Medical College According to the provisional programme, the annual representative meeting of this year will be at the British Medical Association House, Tavistock Square, London, W C 1, on July 18–22 The statutory annual general meeting will be held in Winnipeg on Tuesday, Aug 26, and on the evening of the same day the incoming president, Prof W Harvey Smith, will deliver his address to the Association An exhibition of surgical appliances, foods, drugs, and books will be open during the Winnipeg meeting The presidents of the sections so far appointed are *Medicine* The Right Hon Lord Dawson of Penn, *Surgery* The Right Hon Lord Moynihan of Leeds, *Obstetrics and Gynæcology* Dr Comyns Berkeley, *Bacteriology, Pathology, Physiology, and Biochemistry* Prof Robert Muir, *Diseases of Children* Dr Robert

Hutchison, *Mental Diseases and Neurology* Sir E Farquhar Buzzard, *Ophthalmology* Mr N Bishop Harman, *Laryngology and Otology* Sir St Clair Thomson, *Preventive Medicine* Dr A S M Macgregor, *Tuberculosis* Prof S Lyle Cummins, *Radiology* Dr A E Barclay, *Medical Sociology and History of Medicine* Sir Humphry Rolleston, *Anæsthesia* Mr Raymond E Apperly The honorary local general secretary of the annual meeting is Dr J D Adamson 102 Medical Arts Building Winnipeg, Manitoba

PROF A C SEWARD, professor of botany in the University of Cambridge, and Prof V Grignard, professor of organic chemistry in the University of Lyons, have been elected associates of the Royal Academy of Sciences, Letters and Arts of Belgium

PROF THOMAS HUNT MORGAN, of the California Institute of Technology, who is widely known for his experimental work on the mechanism of inheritance, has been elected president of the American Association for the Advancement of Science and will preside at the 1930 meeting in Cleveland

DR J S PLASKETT, Director of the Dominion Astrophysical Observatory, who has been awarded the Gold Medal of the Royal Astronomical Society for his valuable observations of stellar radial velocities and the important conclusions derived from them, will deliver the George Darwin Lecture of the Society at the ordinary meeting on May 8

THE President and Council of the Royal Society have appointed Dr A S Parkes to the Foulerton Research Studentship, rendered vacant by the appointment of Dr R J Ludford to a senior post on the staff of the Imperial Cancer Research Fund Dr Parkes at present holds a Senior Beit Research Fellowship and is working in the Department of Physiology and Biochemistry at University College, London

THE following have been elected officers of the Royal Meteorological Society -*President* Mr R G K Lempfert *Treasurer* Mr Francis Druce *Secretaries* Dr C E P Brooks, Mr W M Witchell, Dr A Crichton Mitchell *Foreign Secretary* Mr C J P Cave *New Members of Council* Mr David Brunt, Prof Sydney Chapman, Dr Bernard A Keen

A CONFERENCE on grassland problems will be held at the Harper Adams Agricultural College, Newport, Salop, on Wednesday, Feb 5, commencing at 2 P M Addresses dealing with the formation, maintenance, and utilisation of temporary and permanent pastures will be given by Dr J A Hanley, principal of the Royal Agricultural College, Cirencester, Mr W B Mercer, principal of the Cheshire School of Agriculture, Reaseheath, and Mr R Boutflour, director of dairy husbandry at the Harper Adams College Each address will be followed by open discussion Arrangements are also in progress for an exhibit of implements especially designed for grassland work The Conference is intended primarily for farmers, but an open invitation to attend is given to all interested in the subject

AN account of the life and activities, literary and other, of Mr H G Wells is being written by Mr Geoffrey West As Mr Wells received his scientific training at the Royal College of Science, and has many friends in scientific circles, Mr West would much appreciate the assistance which any of them may care to afford in the way of reminiscences, impressions, or letters (or transcripts of letters), especially any referring to Mr Wells's earlier years or to specific activities Original letters (or transcripts to be returned) will be handled only by Mr West, and sent back without delay by registered post Matter may be sent direct to him at Acacia, Dane Bridge Lane, Much Hadham, Herts, or c/o Messrs Gerald Howe, Ltd, 23 Soho Square, London, W 1

AT the monthly general meeting of the Zoological Society of London, held on Jan 15, it was stated that the total number of visitors to the Society's Gardens during the past year was 2,047,090, the receipts amounting to £65,933, showing a decrease of £5723, as compared with 1928, and an increase of £86 as compared with the average for the corresponding period of the previous five years The number of visitors to the Aquarium during 1929 was 422,929, the receipts amounting to £15,657, showing a decrease of £1736, as compared with 1928

THE Diary for 1930 issued by the *Chemist and Druggist*, which has been sent to us, is a considerable volume, containing not only diary proper but also an extensive trade directory and a buyers guide a summary of the legal enactments which affect the pharmacist, formulæ of approved remedies and toilet accessories and much other useful information

A REVIEW of artificial light therapy, with records of its value in medical and surgical practice, compiled and edited by Dr R King Brown, has been issued by the Actinic Press (17 Featherstone Buildings, W C 1, 2s net) As reports have recently appeared casting some doubt on the value of artificial light treatment, this pamphlet will be of use as presenting evidence on the other side

FUR FARMING continues to gain adherents in Great Britain It was stated recently in the *British Fur Trade* that the number of silver fox farms in Great Britain had increased from 19 in 1928 to 32 in 1929, and the number of foxes from 500 to 801 In view of the wide interest in this new industry, attention may be directed to a leaflet, "Hygiene in Fox Farming", just issued by the Biological Survey Bureau of the U S Department of Agriculture No attempt is made in this 6 page leaflet to discuss diseases of foxes or their treatment, but directions are given for simple measures of hygiene and sanitation which may be employed with advantage by any fox farmer

MESSRS Bernard Quaritch, Ltd 11 Grafton Street, W 1, have just circulated a catalogue of their publications and of remainders Librarians and collectors should find it of service

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A second assistant pathologist at St Mary's Hospital W 2

—The Secretary, St Mary's Hospital, Paddington, W 2 (Jan 28) An assistant pathologist at Ancoats Hospital, Manchester—The Gen Supt and Secretary, Ancoats Hospital, Manchester (Jan 28) A demonstrator in pathology and bacteriology in the University of Leeds—The Registrar, The University, Leeds (Jan 31) A head of the Mechanical Engineering Department of the School of Engineering and Navigation, Poplar—The Education Officer (T 1), The County Hall, Westminster Bridge, S E 1 (Feb 1) A lecturer in biology at the Cheshire School of Agriculture—The Principal, Cheshire School of Agriculture, Reaseheath, Nantwich (Feb 8) A foreman recorder and demonstrator at the Denham Demonstration Station of the Middlesex Agricultural Committee—The Secretary, Education Offices, 10 Great George Street, S W 1 (Feb 8) A lecturer in physiology in the University of Stellenbosch—The Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, W C 2 (Feb 15) A lecturer in entomology in the University of Sydney—The Agent General for New South Wales, Australia House, Strand, W C 2 (Feb 28) An assistant agricultural instructor in the department of the Federated Malay States — The Private Secretary (Appointments), Colonial Office, 2 Richmond Terrace, Whitehall, S W 1 (Mar 1) A professor of mathematics in the Queen's University of Belfast—The Secretary, Queen's University, Belfast (April 30) A junior physicist or engineer for research work on problems of heat conduction and insulation, a junior physicist or engineer for research work on aeronautics, a junior physicist for research work on electrostatics, a junior physicist for research work on X rays, a junior physicist for research work on photo electricity and television, a junior physicist for research work on ultrasonics, a junior physicist or physical chemist for research work on radioactivity, an assistant research physicist for work on electrical engineering, an assistant research physicist for work on aerodynamics and hydrodynamics, an assistant research physicist for work on mathematical physics, all at the National Research Laboratories of Canada—S P Eagleson, Secretary, National Research Council, Ottawa, Canada A junior pathologist and a junior soil chemist at the Rubber Research Institute of Malaya—The Secretary, London Advisory Committee, Rubber Research Institute of Malaya, 2 4 Idol Lane, Eastcheap, E C 3 A secretary of the Institution of Structural Engineers—The President, Institution of Structural Engineers, 10 Upper Belgrave Street, S W 1 A professor of zoology in the University College of North Wales, Bangor—The Registrar, University College of North Wales, Bangor

Our Astronomical Column

Wilk's Comet—Dr C H Smiley has deduced the following orbit of this comet from observations on Dec 21, 29, and Jan 5

$$\begin{array}{ll} T & 1930 \text{ Jan } 22\ 3005 \text{ U T} \\ \omega & 157^\circ\ 31'\ 1'' \\ \Omega & 179\quad 2\quad 27 \\ i & 124\quad 30\quad 10 \\ \log q & 9\ 827489 \end{array} \left.\begin{array}{l} \\ \\ \\ \end{array}\right\} 1930\ 0$$

Dr A C D Crommelin obtained the following observation on Jan 19, when the comet was bright enough to observe before the end of twilight

	R A 1930 0	S Decl 1930 0
Jan $19^d\ 18^h\ 6^m\ 3^s\ 7$	$21^h\ 41^m\ 48^s\ 03$	$1^\circ\ 9'\ 9''\ 7$

The comet was moving south and approaching the sun in Right Ascension It is not likely that further observations will be obtained in Europe, but Mr J P Moller has prepared an ephemeris for March and April for the use of southern observers (*I A U Circ*, No 244) Judging from its present brightness the comet should be followed at least until mid April, when it will be in Decl -49°, and distant from the sun 1 66 units

Changes in the Period of the Variable Star *R* Hydræ—*Astr Nach*, No 5669, contains an article by R Muller on the remarkable changes in the period of this variable As it occasionally reaches mag 3 5 at maximum according to Chandler, and is seldom fainter than mag 4 9 at that time, it is an easy object to the naked eye and records go back to the year 1662, H Ludendorff deduced from these that the period was then 486 days and that it increased to a maximum of 507 days about 1708, records are then scanty up to 1784, at which date the period was just under [illegible] days It then diminished rapidly and fairly uniformly, early in the present century it was little above 400 days According to Mr Muller, it has now begun to increase again He shows that Ludendorff's formula for the date 1915 needs considerable modification, he gives the formula for the dates of maximum $J\ D\ 2423040\ 0 + 411\ 7\ E + 0\ 8838\ E^2$, the first date is 1921, Dec 16 As no law has yet been determined for the changes of period, the terms depending on the square or higher powers of E are only provisional

Revision of Newcomb's Occultation Memoir—Newcomb was engaged for thirty years on this important memoir, which was finished during his last illness It discusses the occultations of stars by the moon observed between 1672 and 1908 The publication since then of Brown's Tables of the Moon enables the comparison between theory and observation to be made more rigorous This has been done by Dr H Spencer Jones in *Mon Not Roy Ast Soc* for November last Corrections of $-1\ 64''$, and $-1\ 78''$ (at the epoch 1800) are found for Brown's values of the moon's perigee and node The corrections to their centennial motions are much smaller than their probable errors Brown omitted Hansen's constant term of $-1\ 00''$ in the moon's latitude, but now admits that a term of about half that amount is required This is confirmed by the occultations

The discussion throws some light on the ellipticity of the earth The reciprocal of this is concluded to lie between 294 and 297 Newcomb's equinox is found to require a correction of $-0\ 71''$ at the epoch 1850, but the correction to its centennial motion is small and doubtful Eichelberger's larger correction of $-0\ 057^{sec}$ per century is concluded to be erroneous The solar parallax was determined from the parallactic inequality, using also recent occultations observed at the Cape, as $8\ 799''$ with a probable error of $0\ 003''$ A large diagram of the moon's errors in longitude shows that the occultations indicated smaller oscillations during the period 1750 to 1830 than those found from Greenwich meridian observations

Research Items

Bushman Craniology.—M. Eugène Pittard, following up his study of Hottentot and Griqua skulls, has contributed to *L'Anthropologie*, T. 39, No. 4, the results of the examination of a series of nineteen Bushman skulls from rock shelters, undoubtedly representing an ancient population. The measurements are studied in detail, but the general results may be summed up as follows. The mean cephalic index is 75·46 for males and 76·90 for females. These indices indicate sub-dolichocephaly. But among the females of the series are two, one sub-brachycephalic, the other brachycephalic, which cannot belong to the ethnic group. The males show no indication of brachycephaly, the highest male index (79·23) being masaticephalic, while the highest female (86·71) is hyperbrachycephalic. In height the majority of the crania are chamæcephalic, one female skull alone is hypsicephalic. The skulls are also mesognathous, one female being prognathous with a gnathic index of 106·59. The facial index, 47·34 male and 46·60 female, brings them within the chamæprosopic class, one female, however, being leptoprosopic. The orbital index is microseme, a few of the females being megaseme. The cranial capacity is 1476 c.c. for the males and 1357 c.c. for females. There are some interesting differences between the male and female skulls, apart from the naturally smaller absolute dimensions in the female. The female are less often dolichocephalic than the male and their mean index is higher. The occipital foramen, which is highly developed in both sexes, is larger in the female than the male, but the female index of prognathism is lower. The nasal index is higher in the female, being 59·35 as against the male index of 58·49. It is probable that the group upon which the study is based had not entirely preserved its primitive purity.

Danish-Carib Crosses.—A contribution to the study of racial crossing in man has been made by Mr. O. A. Merritt Hawkes (*Jour. of Heredity*, vol. 20, No. 10), who describes the descendants through four generations from a mating which took place about 1770 between a Frenchman in the West Indies and an Indian woman, probably a Carib. Their daughter married a blue-eyed Dane and had six children. Photographs of many of these individuals and their descendants are given. The Indian characters are regarded as dominant over European in F_1, but it is doubtful if this term is strictly applicable. The general points distinguishing the two races are given. An F_1 woman married to a Dane produced a boy and a girl of Danish type, fair skin with blue eyes, and three girls and a boy with dark hair and eyes and more or less Indian features. Hence this family showed segregation. Similarly, one of the dark daughters married to a blonde, blue-eyed Dane had five children, two Danish in type, one intermediate or mixed, and two remarkably Indian in appearance although reared in Copenhagen. The results in this and the fourth generation suggest a tendency to segregation of Danish and Carib types, or in other words, to linkage of the respective racial characters. But the appearance of mixed types as well indicates that such linkage is incomplete. That the son of a partly Carib woman and a Dane can be more Indian in 'type' than his mother is an interesting fact which requires further analysis.

Spread of the Mountain Hare.—The mountain hare or arctic hare is a native of Scotland north of the line of the Forth and Tay, but at various times about the middle of the nineteenth century it was set free in the southern uplands of that country. From two main centres of dispersal there it has succeeded in colonising the whole of the south country and has crossed the borders into Northumberland and Cumberland. From information furnished by the shepherds on the hill pastures Dr. James Ritchie (*Scot. Nat.*, p. 169, 1929) has traced the progress of the hare's movements, showing that less than half a century sufficed for the colonisation of this considerable area.

Behaviour of Starlings in Winter.—Starlings are well known to congregate in common roosting places in winter and the behaviour associated with their roosting habits has been the subject of an intensive and interesting study by V. C. Wynne-Edwards (*British Birds*, October and November 1929). The area investigated was in Devon and Cornwall, and in its 3000 square miles the starling population was estimated to be of the order of five millions. Winter roosts were ten in number, and the two most populous accommodated about 500,000 birds each, while in the others numbers ranged from about 50,000 to a quarter of a million. The flights of the birds to and from their feeding grounds were traced, and it was discovered that the feeding area of one of the largest roosts covered approximately 130,000 acres, and that while in general not more than five to fifteen miles were covered in the daily flight outwards, flights extended up to 24 miles. Apparently the flight stimulus is associated with the increasing intensity of light at dawn and its waning towards evening, for a table of observations shows a close correlation between the start of the first flight each day and sunrise. Roosting in winter is probably a much more common habit in birds than has been realised. In his own district, the author has traced twelve species of birds to roosts, some of considerable size, and he adds some interesting speculations on the advantage of the gregarious habit.

New Method of Treating Frequency Curves.—In a particularly arresting paper appearing in the *Journal of the International Council for the Exploration of the Sea*, vol. 4, No. 2, 1929, H. J. Buchanan-Wollaston and William C. Hodgson describe at some length a new method of treating frequency curves in fishery statistics. The method is based on three assumptions, quite new and fundamentally different from previously existing ideas on the treatment of statistical data, and producing fundamentally different results. Their applicability depends upon treating each sample of fish measurements separately, or on treating together only such data as are limited to a very restricted 'area' in time and space. It seems worth while to quote in full the authors' definitions of their three assumptions. They are: (1) that every frequency curve of fish measurements is compounded of several substantially different symmetrical curves of narrow range, similar to the curve of error; (2) that every maximum shown in the rough frequencies corresponds to a real mode; and (3) that the comparative rough frequencies given by the data, even if very small in number, correspond sufficiently well with the actual frequencies of fish at each length on the ground to be treated as absolutely correct, with an insignificant error. These assumptions, the authors wisely add, can be justified only by results. Some results of the application of the new method, particularly to herring data, are given.

***Terra Nova* Madreporaria.**—Prof. J. Stanley Gardiner records ten species of Madreporaria from the Antarctic (glacial) area of the Ross Sea and from the temperate

area north of New Zealand (Madreporaria (b) Turbinolidæ and Eupsammidæ, Cœlenterata Part 4, British Antarctic (*Terra Nova*) Expedition, Zoology, 5, No 4, 1910 Natural History Report, British Museum (Natural History), 1929) Of the Madreporarian corals obtained by the *Terra Nova* Expedition, those from the Atlantic Ocean and belonging to the genus *Favia* have already been reported on by Prof George Matthai (*Zoology*, 5, No 2, 1919) The present reports deals with the remainder, three out of the ten being new species The genus *Gardineria* of Vaughan is recognised, to which two of the new species belong, a possible third or even two more being mentioned Much of the text is taken up with a description of *Gardineria antarctica* n sp, which is figured in a good plate with *Gardineria lillei* n sp, also from the Antarctic, *Dendrophyllia japonica* Kent and *Flabellum harmeri* n sp, the last two from New Zealand Notes on collecting and preservation are a useful addition to this work The author prefers spirit for preserving corals If kept in the dark, the flesh alters little or not at all in thirty years

Arthropods as Intermediate Hosts of Helminthes — Maurice C Hall (*Smithsonian Misc Coll*, vol 81, No 15, 1929) has prepared a useful list of arthropods which have been shown to act as intermediate hosts of helminthes The list of arthropod hosts of cestodes is prefaced by the remark that the known number of such cases is so small that a comprehensive list can be given, but since the life histories of only about one per cent of the known species of tapeworms have been worked out, generalisations must be made with care Probably many cestodes now known as having only one intermediate host will be found to require two The list of cestodes and their intermediate hosts (10 pp), of trematodes (9 pp), of nematodes (15 pp), and of Acanthocephala (4 pp) is followed in each case by comments on the life histories of the different families The next part of the work consists of a table of arthropod hosts of helminthes arranged systematically—the orders of insects, the Arachnida, Myriapoda, and Crustacea There are altogether 143 species of helminthes parasitic in vertebrates which have arthropods as intermediate hosts and for which the primary hosts are known, there are also 61 larval forms for which the primary host is unknown The author pleads for better co operation between parasitologists and those who work on arthropods and suggests that the latter should direct the attention of parasitologists to any larval helminthes which they find during the dissection of insects

Peter I Island —This antarctic island, lying off the antarctic continent to the south of the Pacific, has seldom been sighted and never explored since Bellingshausen discovered it in 1821 In 1927 it was visited by the Norwegian whaler *Odd I*, and again in 1927 by the *Norvegia* An article on the explorations, with a map of the island, by Capt W Sachse, appears in *Petermanns Mitteilungen*, Hefte 11 and 12, 1929 The island appears to be entirely volcanic and fringed with steep cliffs It is almost entirely covered with ice even to the summit, which is at about four thousand feet The length of the island is about fifteen miles, and the breadth about seven miles The position of the centre is lat 68° 50′ S, long 90° 35′ W There is no harbour of any value, and landing is practically impossible

The Length of a Nautical Mile —The nautical mile being one minute of longitude varies in length from equator to poles The variations depend of course on the figure of the earth The accepted mean of 6076 8 feet is taken in practice as 6080 feet for navigational purposes This is 1853 2 metres At the International Hydrographic Congress held at Monaco in April 1929, it was decided to recommend that the nautical mile should have a length equal to 1852 times that of the standard metre This has an equivalent of 6076 0 feet In *La Géographie* for Sept-Oct 1929, M Vallaux gives some of the lengths now in use in various countries The figure of 1852 metres has been used in France since 1906, and also by Germany, Denmark, Iceland, Norway, Sweden, Greece, and Japan Belgium has a mile of 1854 metres, Italy and Spain 1854 8 metres, and the United States 1853 25 metres or 6080 2 feet

The 'Green Flash' at Sunset —A satisfactory account of the origin of the 'green flash' of the upper limb of the sun when it disappears at sunset is given by Lord Rayleigh in the January issue of the *Proceedings of the Royal Society* As he points out, the colour cannot be due to retinal fatigue, since it can also be seen at sunrise, and it has come to be generally recognised that it is due to the dispersion that accompanies atmospheric refraction, the green usually seen being more refrangible than the general light of the disc at the horizon The main point remaining to be decided was whether the normal dispersion of the atmosphere was sufficiently large to explain the effect, and Lord Rayleigh has now shown that it is in fact probably adequate, and has also been able to demonstrate a 'flash' in some neat laboratory experiments with a glass prism of small angle as the dispersing medium As possible causes of the natural 'flash' being green rather than the more refrangible blue, he mentions the inferior visual luminosity of the pure blue of the spectrum, and the relatively greater toll taken of the blue by atmospheric scattering Lord Rayleigh refers to Prof R W Wood's suggestion (NATURE, Mar 31, 1928, vol 121, p 501) that the flash is seen best when for some reason the atmospheric dispersion near the horizon is unusually large, and remarks that, if this is the case, sunset should be deferred upon such occasions by a time of the order of two minutes, a phenomenon for which he hopes to have search made in tropical seas

Protective Devices on Electric Supply Networks — The necessity of protecting the networks of cables and overhead wires which now link electric power stations with their consumers and with other power stations from accidental damage due to short circuits or lightning has led to an extensive use of protective devices of all kinds, the manufacture of which is an important industry In modern practice, networks, instead of receiving, as formerly, a supply from a single feeding point, receive it from many points As a result, when a 'fault' occurs, the direction of the current flow in a main depends upon the position of the fault in the network Those devices, therefore, which act when the current flow is in one direction only are no longer applicable The more elaborate protective devices being tried are naturally more expensive, but engineers regard this cost as the insurance premium for their mains On the Continent, the neutral point of a network of overhead power lines is generally insulated from the earth If a fault develop on one of the mains, it is usually followed by an arc carrying a large current Damage is usually done by the arc, and so a special device for its suppression called a Petersen coil is connected between the neutral point and the earth It is adjusted so that in the event of the capacity to earth of one of the mains being short circuited, the coil resonates with the capacity of the remaining mains and thus lowers the voltage and extinguishes the arc When an insulator

flashes over, the operation of the coil is so quick that the arc is usually suppressed before the other safety devices begin to act T W Ross and H G Bell in a paper read to the Institution of Electrical Engineers on Jan 9 discussed the merits of the various types of protective devices used for the protection of three phase lines and 'feeders' They conclude that at the present time it is possible to protect adequately the mains of a supply network by means of some of the devices that are in use, but as the networks continue to grow, still more elaborate devices will soon be required

History of Bell-founding—At a meeting of the Newcomen Society held on Dec 18, Mr A A Hughes read a paper on the art of bell founding In England, the art can be traced back to Saxon times, there being records of bells at Whitby, York, and Canterbury in the seventh and eighth centuries, while in the tenth century seven bells were presented to Crowland Abbey The earliest instructions recorded in Great Britain are contained in a manuscript by Walker of Odyngton, a monk of the time of Henry III preserved in the library of Corpus Christi College Cambridge Mr Hughes gave particulars of the methods used in designing, moulding casting, and tuning bells, and said that fundamentally the actual processes of moulding and casting have altered only slightly during the last six or seven centuries Quality of tone depends more upon correct shape and correct proportions of thickness at various points than upon the quality of metal The theory was apparently partly understood by a few early English founders, and it was certainly understood by some sixteenth and seventeenth century Flemish founders After the design is settled, a 'strickle' is used for forming the moulds which are built up from bricks and loam, the surfaces of the moulds being dressed with plumbago and polished Bell metal contains about 76 per cent copper and 23 per cent tin Great advances have been made in the tuning, the first machines for which were made at Gloucester and at the Whitechapel Foundry about a hundred years ago In olden times surplus metal was removed by hand, but vertical lathes are now used, while the note and the harmonic tones are recorded by registering tuning forks

Isotopes of Oxygen—The presence of an isotope of oxygen of mass 18 in the earth's atmosphere was reported by Giaque and Johnston (in NATURE of Mar 2, 1929, p 318), and in the December number of the *Journal of the American Chemical Society* these authors show that the atmospheric absorption spectra obtained by Babcock at Mount Wilson Observatory indicate the presence of another isotope of mass 17 A series of very weak lines is interpreted as due to the molecule $O^{16}O^{17}$, present to the extent of 1 part in 5000 as a maximum The $O^{16}O^{18}$ molecules are present to the extent of 1 part in 625 The existence of oxygen of mass 17 has previously been reported by Blackett, by Kirsch and Pettersson and by Harkins and Shadduck from data obtained on collisions between α particles and nitrogen nuclei One or two collisions per 100,000 result in combination of the α particle with the nitrogen, forming an unstable isotope of fluorine, which immediately ejects a proton and becomes oxygen 17 A full list of calculated and observed lines in the *A* bands is given in the paper

Production of Helium from Monazite—The industrial sources of helium have in recent years attracted a considerable amount of attention in view of the use of this gas in place of hydrogen for filling the gas containers of airships In the United States a considerable amount of helium extracted from natural gas, the rich varieties of which contain about 1 per cent of helium, is available and in use An alternative source of helium which is of great interest in the possible applications of the gas in the British Empire is the mineral monazite, the raw material for the production of thoria for incandescent gas mantles, which is found in large quantities in Travancore, India In the issue of Dec 27 of the *Journal of the Society of Chemical Industry*, Mr R Taylor, who has been working in the Chemical Research Laboratory at Teddington under the direction of Sir Richard Threlfall and his successor, Prof G T Morgan, describes some interesting experiments on the production of helium from monazite The mineral contains about 1 c c of helium per gram, and thus in the working up of every 100 tons of monazite about 100,000 litres of helium are allowed to escape into the atmosphere The gas escapes on heating, and the paper describes how it is purified by treatment with hot metallic calcium, which absorbs nitrogen and other gases It is advantageous to remove most of the nitrogen by heated magnesium before treatment with calcium Working drawings of the apparatus are given in the paper

Autoracemisation—The spontaneous or autoracemisation of bromosuccinic acid has been studied by T Wagner Jauregg, who discusses the reaction at some length in a paper in the *Sitzungsberichte* of the Vienna Academy of Sciences, vol 138, Suppl p 791 The author has been able to show that the racemisation, so far from being spontaneous, is catalysed by mere traces of hydrogen bromide, which are too small to be precipitated as silver halide and have hitherto escaped detection Racemisation can be eliminated either by repeated distillation under very low pressures, or by the presence of certain salts or metals such as silver, copper mercury, or zinc, but not magnesium or platinum The catalytic activity of the ions increases rapidly in the order chlorine, bromine, and iodine, the latter being nearly twelve times as active as chlorine The velocity of racemisation varies also with the solvent, acetone being very much more active than methyl alcohol Other ions appear to be inactive In discussing the mechanism of the process, the author suggests that the halogen ion on approaching the asymmetric molecule induces a charge upon it in such a way that the hydrogen atoms are detached as protons from the asymmetric carbon atoms (cf Lowry, *J Chem Soc*, p 2557, 1927) A stream of valency electrons begins to flow out through the carbonyl oxygen of the acid group to meet the free protons, thus enabling the hydrogen atoms to re enter the molecule As this process involves enolisation, the asymmetry is destroyed by the temporary formation of a double bond, so that the regenerated molecules are of necessity racemic in structure

Fuel Testing in Canada—The report of "Investigation of Fuels and Fuel Testing for 1927", issued by the Canadian Department of Mines (Ottawa, F A Acland, 1929, Paper No 696), gives a belated account of the activities of the Dominion fuel research organisation for that year The report shows that State effort is being given to encourage the domestic use of coke instead of anthracite, supplies of which are difficult This gives point to the recorded study of the coking properties of Canadian coals The gasoline survey reveals a slight deterioration in the quality of motor spirit A study of peculiarly Canadian importance deals with the assay of the bituminous sands which occur in Alberta

A Table of Electronic Configurations of the Elements

MR ROY GARDNER gave an interesting paper on "A Method of Setting out the Classification of the Elements" at a recent meeting of the New Zealand Institute The paper included the accompanying Table, which shows the distribution of electrons into groups corresponding to the principal quantum numbers for all the elements and at the same time preserves the most essential features of the two dimensional arrangement of Mendeléef Elements having the same complete groups (that is, all stable groups of 8 or 18) are placed in the same horizontal row, and the vertical columns include elements with the same number of electrons in the incomplete outer groups The electronic configurations are those given by Sidgwick ("Electronic Theory of Valency", 1927) An asterisk marks elements for which the 'normal' atom is thought to have only one electron in the outermost group, but as practically all these give divalent ions, the point is of minor interest chemically Distribution of electrons into k subgroups is unnecessary, these have at present little significance for chemical purposes, and in any case the subgroups are considered to be filled in order to the maxima 2, 6, and 10 The electronic arrangements are read off as shown by the following examples

	0	1	2	3	4	5	6	7	2 9	2 10	2 11	2 12	2 13	2 14	2 15	2 16	2 17	2 9 19	2 9 20	2 9 30	2 9 31

The existence of four types of elements is emphasised —(1) those with all groups complete, (2) those with one incomplete group, (3) those with two incomplete groups (transition elements), (4) those with three incomplete groups (rare earth elements) The upper limits of existence of covalencies of 8, 6, and 4 are marked by heavy horizontal lines

Electrical Research in Industry

ONE of the most important functions of the research department of a manufacturing company is to study the development of science with the view of its industrial application At the beginning of the War there was a wide gulf between research and industry, although it was beginning to get narrowed In 1915 there was a national movement in Great Britain to accelerate the application of science to industry, and this contributed largely to our industrial progress

We have received from Messrs. Metropolitan Vickers Electrical Co, Ltd, of Trafford Park, Manchester, an account of their research activities during 1929 This bears out how advantageous it is to make full use of scientific methods and the latest scientific developments in industry An example of this is the development of a low vapour pressure grease for use with vacuum pumps and valves This has made commercially possible the manufacture of vacuum apparatus which can be taken to pieces With the highest vacua used at the present time, grease can be used for sealing the joints which has no appreciable evaporation products The research work on the 'creep' of steels and other materials has led to important results Apparatus has been made which enables the creep characteristics to be determined immediately by comparison with a standard up to temperatures of 800° C The study of the rates of strain has enabled a tolerance limit to be fixed in turbine construction The effect of combina-

tions of various stresses in thin walled tubes has led to important results It has been found that the structural changes which occur in carbon steels at high temperatures also take place at the working temperatures of present turbine practice In all future designs, the rate of creep and permanent distortion of the steel will have to be taken into account

Many experimental turbine tests were carried out The work has demonstrated that the correct formation of blade passages in turbines varies in different parts of the machine A novel activity is the development of a means of studying nozzle efficiency by observation of the stream flow of the steam This method has now been developed to a stage where it is giving very valuable guidance on the understanding of steam flow phenomena

The quantitative tests made in the new acoustical laboratory on the noise emitted by electrical and mechanical apparatus has led to important results which are now being applied in practice The 'skin' effect produced when electric currents flow in large conductors has been studied to help with the design of bus bars for central stations In this connexion a study of the flow of heat from hot bars along irregular paths has also yielded useful results The design of induction furnaces has now advanced so far that a furnace having a capacity of one ton is being constructed

A cathode ray oscillograph has been completed, the first of its kind in England, for taking accurate oscillograms of very rapid electrical disturbances The periodic time of the instrument is of the order of the millionth of a second Much work has been done on domestic apparatus which has led to great improvements A new range of fire elements has been developed and the existing elements used in hot plates, grills, and ovens have been made more efficient and trustworthy An investigation has been made on the breakdown voltage of very long air gaps and sparks up to fourteen feet long have been obtained The safe working limits under all conditions of the high voltage testing equipment have been determined High voltage tests have been particularly useful in testing insulators for use on the national 'grid' for distributing electrical energy

Water Supply of London

IN a lecture delivered before the Junior Institution of Engineers on Jan 17, Mr G Andrew Marshall gave some interesting figures indicating the immensity of the responsibility involved in undertaking the supply of water to so great an area and population as is comprised in the district served by the Metropolitan Water Board Thus the area supplied is about 560 square miles in extent, the population 7,381,000, and the quantity of water distributed last year was 100,723 million gallons, the average daily supply being 276 million gallons, a little more than the half of which quantity was equivalent to the combined supply for Manchester, Liverpool, Birmingham, Sheffield Nottingham, Leeds, and Brighton The net amount received for water rental amounts to about £4,500,000 a year, and the capital debt is £53,856,000 The number of officers employed by the Board is about 950 and of workmen 4290 The capacity of the storage reservoirs is 19,657 million gallons, and of service reservoirs there are 92, holding 321 million gallons, there are 176 acres of filter beds, about 7000 miles of mains, and a total horse power of 27,270 is required to pump water through the system

The raw water comes from three sources, the largest, giving 58 per cent of the total, being the River Thames, 24 per cent comes from the River Lea, and the remainder from wells sunk in the Thames Valley and in Kent at Addington, Eynsford, etc Notwithstanding the great capacity—321 million gallons—of the service reservoirs, the daily quantity used—276 million gallons—makes continuous pumping necessary, and the reservoirs in many cases only serve as jack heads and cannot generally be looked upon as reservoirs for the storage of filtered water for anything but a short period

The enormous capacity of the storage—as distinct from the service—reservoirs, namely, 19,657 million gallons, is essential to compensate for the great variation in the flow of the river sources of supply at different periods of the year Thus in December 1929 the flow of the River Thames as gauged at Teddington Weir was nearly 10,500 million gallons in twenty four hours, whereas in the previous July it was only 170 million gallons, about sixty times less than the former figure It is, therefore, only possible to collect water at favourable periods of the year, and the reservoirs have to be of such capacity as to be able to span the periods of drought

In addition to storing water, the storage reservoirs have another function—the clarification of the water by precipitation of suspended particles of matter and its improvement from a bacteriological point of view Thirty days was generally considered a desirable period, in this time the number of bacteria of all kinds was reduced and the microbes of water borne disease devitalised The systematic purification of Thames water was commenced more than a hundred years ago by James Simpson, the engineer of the old Lambeth and Chelsea Water Companies, who passed it through sand filters Many improvements in this system have been made, though the principle remains the same, and in the latest developments primary and secondary sand filters are installed, the conjunction enabling the slow sand filters to be worked at a faster rate The normal rate of filtration by slow sand filters varies from 1½ to 2 million gallons per day for a bed of about 1 acre, but by passing prefiltered water on to them they can be made to work at about three times that speed

Composition of the Population of Canada.

A NEW departure by the Dominion Bureau of Statistics at Ottawa is the publication of a volume entitled "Origin, Birth, Nationality, and Language of the Canadian People" In this volume the data of the population according to the figures collected in the census of 1921 are analysed in some detail and made to afford much interesting and some times illuminating information relating to the composition of the Canadian people, especially in such matters as affect immigration in relation to growth of the population

In 1921, about 55 per cent of the Canadian people was of British stock and nearly 28 per cent French, other European stocks constituting 14 16 per cent of the population Of these, north-western Europeans (other than British or French) exceeded the Latin and Slav elements by approximately 20 per cent, though the latter group has in recent census periods been rapidly overtaking the former

In 1921, about 97 per cent of the French Canadians and three quarters of the people of British stock were Canadian born, elements from other parts of Europe

showing proportions of Canadian born ranging from 50 per cent to 80 per cent, those of the Germanic group being highest Many of the people of Scandinavian or Germanic origin reach Canada from the United States During the decades elapsing between the censuses of Canada, the proportion of the population which is Canadian-born has continued to decrease, and there has been a corresponding increase in the immigrant proportion

The various provinces of Canada present different racial textures, and it is not surprising that in Quebec 80 per cent of the population is of French origin and only 15 12 per cent of British stock In Ontario the position is reversed, more than 77 per cent being of British stock and more than 8 per cent of French stock, nearly 12 per cent being of other European origin In the prairie provinces the proportion of European stock other than British or French was three times greater than in Ontario, people of British stock representing about 60 per cent of the population of Alberta, nearly 53 per cent of that in Saskatchewan, and more than 57 per cent of that of Manitoba In British Columbia nearly 74 per cent was of British origin, slightly more than 2 per cent of French origin, and nearly 12 per cent of other European origin, persons of Asiatic origin forming in this Province 7 57 per cent The British and French stocks continue to predominate in the maritime provinces

Discussing the urban and rural distribution of the Canadian population, it is of interest to note that approximately a quarter of the population is resident in cities of 25,000 and more, the cities being more predominantly British than the rural districts Of the people of British stock, 28 17 per cent live in cities, the corresponding percentage for the French stock being 22 45 per cent

University and Educational Intelligence

CAMBRIDGE —Mr F L Engledow, fellow of St John's College, Cambridge, and University lecturer in agriculture, has been elected to the Drapers professorship of agriculture, vacant by the death on Nov 6 of Prof T B Wood

The Vice Chancellor announces that the Royal Society, in virtue of its reversionary interest in the residue of the estate of the late Mr E W Smithson, holds a sum yielding about £1200 a year, and that the regulations now published have been adopted by the Royal Society after consultation with the Council of the Senate in order to give effect to the terms of the bequest Accordingly, at the Congregation on Friday, Jan 24, the Regent House will be asked to pass a Grace to the effect that Prof A C Seward, Master of Downing, Mr W H Mills, of Jesus College, and Mr R H Fowler, of Trinity College, be appointed members of the committee for the administration of the Smithson Research Fund The Royal Society will appoint four members of the committee The income of the fund is to be devoted to the establishment of a fellowship for research in natural science with the view of the discovery of new laws and principles, to be called the Smithson Research Fellowship The research must be carried out in the University of Cambridge provided that an appropriate laboratory is prepared to offer the accommodation needed The fellow may not undertake any paid work outside the research without the written permission of the Committee The Committee will normally not withhold such permission to the holding of a paid teaching appointment in the University of Cambridge, provided that this does not involve a total of more than forty eight hours of actual teaching in any one academic year, but it will not permit the holding of an appointment for college teaching or supervision of students' work The total emolument of a fellow will be made up to £800 a year during the first two years of his tenure

LEEDS —Dr J H Richardson has been elected to the Montague Burton chair of industrial relations Dr Richardson is at present Assistant Chief of Section in the Research Division of the International Labour Office of the League of Nations at Geneva

A DISCUSSION was held on Jan 3 at the annual meeting of the Science Masters' Association on School Certificate Biology Mr J W Stork (Charterhouse) was in the chair Mr E H Michael (Swindon) opened the discussion by reading a paper dealing with the gradual growth of biology in schools, and the general problems in connexion with fitting it into the school certificate curriculum The programme of the meeting included a series of propositions which were set out in the leading article in NATURE of Jan 11 These were next discussed in turn, the chairman making it clear that they were not to be regarded as representing a syllabus, but merely as points on which the discussion might be focused Resolutions were passed recommending, among other things, that biology should be included as a separate subject in every school certificate examination syllabus, and should rank for matriculation, that school certificate biology, though intended primarily for general education purposes, must also provide preparation for specialised higher certificate work, that questions should be set in the examination which demand a practical acquaintance with experiments and types, but there should be no separate practical examination, that as few 'types' as possible should be included in the syllabus, and that the syllabus should include "An elementary knowledge of, at least, the evidences of Evolution"

UNDER Section 4 of the University of Durham Act, 1908, the Sunderland Technical College was entitled to be affiliated to the University of Durham in the Faculty of Science as soon as it had satisfied certain conditions During the past few years a considerable extension has been added to the College buildings containing a large engineering laboratory equipped with types of Diesel, steam, oil, gas, and petrol engines, air compressor, carbon dioxide refrigeration plant, and a large number of accessories, such as pyrometers, indicators, etc The materials testing laboratory has also been remodelled and the equipment brought up to date, and hydraulic plant installed for experimental purposes The electrical engineering laboratory has been enlarged and equipped with plant and instruments for tests on all types of electrical machinery, and the physics laboratory accommodation has been extended and much equipment has been added Upon the completion of this work the local education authority in May of last year made formal application for affiliation to the University The Statutory Committee appointed by the University of Durham reported favourably and invited the Chancellor of the University to declare the College to be affiliated to the University in the Faculty of Science as from the close of the present academical year Students of the College, therefore, will now be entitled to be admitted as candidates for degrees in engineering and electrical engineering in the University of Durham without being required to attend lectures or instruction other than the teaching provided by the College, and the executive authority of the College will be entitled to nominate two persons to serve on the Senate as its representatives

Historic Natural Events

Jan 26, 1884 Great Storm —The centre of a very deep barometric depression appeared off the west coast of Ireland on the morning of Jan 26, and passed across Scotland to Aberdeen, which it reached at mid night At Ochtertyre, Perthshire, the barometer fell to 27 359 inches (corrected for gravity), or 926 5 milli bars at 8 30 P M, the lowest known sea level pressure in the British Isles A severe gale was felt in north east England, the velocity at Alnwick between 11 30 P M on Jan 26 and 12 30 A M on Jan 27 averaging 76 miles per hour The Observatory on the summit of Ben Nevis was in operation at the time, and the storm there was exceedingly violent

Jan 27, 1889 Wind Storm —During a thunder storm at Sydney, New South Wales, some damage was done by a violent gust of wind One house was completely shattered, the roof being lifted off and the walls blown outwards At the Observatory three miles away, the highest gust recorded was 68 miles per hour

Jan 27, 1920 High Wind —A severe gale on the west coast of Ireland was remarkable for a gust of wind at Quilty, County Clare, which reached the highest velocity known in the British Isles The wind increased steadily in force until about 8 A M, when it was 51 miles per hour At 8 20 a violent gust occurred, the pen of the pressure tube anemograph rushed up above the top of the chart, for it caught in the upper edge and spluttered as it came down The indicated speed of the wind was at least 111 miles per hour This isolated squall did not last much more than a minute, after which the general velocity fell again to 50 miles an hour

Jan 29, 1921 Storm in Washington and Oregon —The severest storm experienced in 200 years At the mouth of the Columbia River, the wind velocity recorded by an anemometer averaged 126 miles per hour over a period of five minutes, and reached 150 miles per hour in a gust Trees four feet in diameter were broken off, the damage to standing timber being the greatest ever experienced in the United States Billions of feet of the finest timber were uprooted and thrown down, much of it was a total loss, as the district is not readily accessible for salvage

Jan 30, 1766 Dust Storm —A violent hailstorm at Gibraltar brought also enormous quantities of dust, which fell so thickly in the streets that in places it is said to have reached to the roofs of the houses, and afterwards one thousand labourers were required to remove it

Jan 30, 1911 Eruption of Taal Volcano —A great eruption occurred in Taal Volcano in Luzon Island, 39 miles south of Manila The chief feature was an explosion scattering scalding mud and ashes that ultimately formed a layer 2½ feet deep to a distance of 6 miles west of the crater The sound was heard for at least 310 miles, and the resulting atmospheric depression was registered by barographs within 186 miles of the volcano Though frequent earthquakes preceded the eruption for three days, no attempt was made to save the inhabitants, nearly all of whom (1335 in number) perished (see under heading Jan 12)

Jan 31, 1918 Fog —With an anticyclone over western Europe, the three days Jan 31–Feb 1 were foggy at many places in Europe, and on Jan 31 occurred the densest fog recorded in London for many years It began to form in the City on the afternoon and evening of Jan 30, but under the influence of light easterly airs it drifted up the Thames Valley, and at the same time increased in intensity During the afternoon and early evening of Jan 31 rail and road traffic was completely paralysed over all the low ground from Hammersmith to Twickenham, and in many places vision was limited to not more than a yard It was a typical example of shallow radiation fog, ending against the slopes of the hills almost as abruptly as a sheet of water

Societies and Academies

LONDON

Royal Society, Jan 16 —**J R Marrack** and **F C Smith** The composition of diphtheria toxin—anti toxin floccules The floccules formed by diphtheria toxin and antitoxin closely resemble serum pseudo globulin Their ultra violet absorption curves are identical The amount of precipitate obtained from a balanced mixture of a given toxin and antitoxin is to a large extent independent of the conditions under which flocculation takes place, particularly of the amount of non specific protein present Lipoid material forms a very small fraction of the floccules The authors consider that the floccules consist mainly of antitoxin, and infer that antitoxin is not merely carried down in the pseudoglobulin fraction but actually is pseudoglobulin —**F G Spear** The delayed lethal effect of radium on tissue cultures *in vitro* Cultures *in vitro* of the choroid and sclerotic of embryo chicks were exposed for varying periods to gamma rays from radium and were afterwards subcultivated every forty eight hours When a delayed lethal effect followed ex posure to radium, it occurred sooner in those cultures which had been exposed to the greater intensity of irra diation for a shorter time than in those subjected to a lesser intensity for a longer time, the product of milli grams of radium and hours of exposure being the same in a given comparison **Sir Frederick Keeble, M G Nelson**, and **R Snow** The integration of plant behaviour (1) Separate geotropic stimulations of tip and stump in roots In seedlings of *Zea Mays* a geotropic stimulus can be transmitted across a dis continuity from a coleoptile tip or root tip to an un stimulated root stump Conversely, the sensitivity to gravity of a geotropically stimulated root stump is increased by an unstimulated coleoptile tip placed upon it, and probably also by an unstimulated root tip — **Charles Todd** Cellular individuality in the higher animals, with special reference to the indi viduality of the red blood corpuscle It is possible in the fowl, by means of simple immunity reactions, to differentiate red blood corpuscles of any particular fowl from those of any other individual of the same species, except in certain cases where there is close blood relationship It appears probable that in the higher animals this individual specificity of the red blood corpuscle is only one example of a general rule applying to most cells of the body —**J Ewles** and **J B Speakman** Examination of the fine struc ture of wool by X ray analysis Photographs have been obtained showing for the first time that wool has a definitely fibred structure The three types of wool investigated in the unstretched state suggest an in teresting transition in structure Cotswold wool has definitely ordered structure and its strongly fibred pattern indicates an elongated cell Geelong 80 merino wool, though fibred, is less so than that of Cotswold wool and suggests an ellipsoidal cell 64 merino wool shows only a trace of ordered arrange- ment and fibring The three types suggest the mode of development The wool cell probably begins as a gelatinous spherical cell, by elongation in the direc- tion of growth, strains may be set up which will give rise to ordered and preferential arrangement, tending to the crystalline state

Mineralogical Society, Jan 14 —Sir Douglas Mawson On the occurrence of potassium nitrate

near Goyder's Pass, M'Donnell Ranges, Central Australia The nitre occurs as encrustations on the walls and impregnations in the wall rock in small caves in dolomitic limestone The roof of the caves consists of a case hardened crust formed by superficial silicification and ferruginisation of the limestone, and it is this impervious crust that has enabled the nitrates, probably of animal origin, to be preserved Mention is made of some other occurrences of mineral nitrates in Australia —**Louis T Nel** A new occurrence of zunyite near Postmasburg, South Africa The mineral zunyite, previously known only from Colorado, has been found in some abundance in altered, highly aluminous, shales and flagstones in the vicinity of the deposits of manganese ore of the Postmasburg District in Cape Province Minute perfectly developed tetrahedra are aggregated in clusters or are disseminated through the rock, which contains also diaspore, kaolin, and leverrierite Most of the tetrahedra are simple, but a few are interpenetration twins with a triad axis as twin axis Analyses agree with the formula $Al_8(OH, F, Cl)_{18}(SiO_4)_3$

PARIS

Academy of Sciences, Dec 23 —**A Danjon** Results obtained during the eclipse of May 9, 1929, by the expedition of the Strasbourg Observatory to Poulo Condore The period of the eclipse was troubled by clouds, but the whole of the projected programme was carried out Three photographs of the corona taken during totality are reproduced in the paper —**A Michel-Lévy** and **H Muraour** The microscopic examination of colloidal powders in polarised light Contrary to the views hitherto held, it is shown that, with explosives of mixtures of nitroglycerine with gun cotton, the examination in polarised light clearly differentiates the different types of powder, as regards the unequal distribution of the proportion of nitric nitrogen The microscopic examination and the determination of the rapidity of combustion are always in agreement, the latter being invariably higher, for the same percentage composition, when the polarising microscope indicates the presence of strongly nitrated fibres of nitrocellulose —**P Mondain-Monval** The spontaneous inflammation of mixtures of air and hydrocarbons The influence of concentration A summary, with diagram, of the results of preceding papers Generally, even when there is no inflammation, a sudden spontaneous increase of pressure is observed in the bomb, an increase impossible to differentiate by external manifestations from a true combustion —**Const Kténas** The limits of the mixed Ægean region An attempt at a geological synthesis —**Paul Wintrebert** The equilibrium changes of the egg and the position of the blastopore in the course of the development of *Discoglossus pictus* —**Jules Amar** The respiratory adaptation of the heart —**Brocq-Rousseu, Mme Z Gruzewska, and G Roussel** The relation of the hydrolysing power of the amylase of horse serum to the serum proteins —**F Vlès, A de Coulon, and J Nicod** Experiments on the action of the amino acids towards tar tumours in mice Treatment with amino acids, alone or mixed, showed several cases of cure of the cancerous tissue in others the normal growth of the tumour was arrested

CRACOW

Polish Academy of Arts and Letters, Nov 11 —**O Nicodym** The condition of Baire —**K Kordylewski** The variable star Tauri 41 1929 The elements are calculated from 76 observations on 15 nights between 1925 and 1929 The time of eclipse is eight hours —**W Swietoslawski** The heat of combustion of camphor, azobenzene, and hydrazobenzene For the heat of combustion at constant volume for 1 gram weighed in vacuum the values obtained are, camphor, 9248 7 cal, azobenzene, 8477 0 cal —**L Marchlewski** Phyllerythrin This substance, when recrystallised from chloroform, forms a stable compound with the latter This dissolved in pyridine, and precipitated by alcohol or by acetic acid, and this treatment repeated several times, yields pure phyllerythrin free from chloroform —**K Dziewonski, Mlle A Glasnerowna, and Mlle J Schoenowna** Researches on the derivatives of α bromoacenaphthene —**K Dziewonski, St Lepiankiewicz, J Moszew, and L Suchem** 1, 4 Dibenzylnaphthalene and its ketonic derivatives —**Z Grodinski** The lymphatic hearts of fossil reptiles

WASHINGTON, D C

National Academy of Sciences (*Proc*, Vol 15, No 11, Nov 15) —**William Duane** On the polarisation of X radiation A horizontal stream of high speed electrons passes through a vertical stream of mercury atoms in the middle of the anode and the polarisation of radiation at right angles to the electron stream was investigated by means of the scattered radiation from a block of carbon The weighted mean value for the degree of polarisation is 0 497 —**F Zwicky** On mosaic crystals It is suggested that structure insensitive properties of crystals are determined by the primary lattice and structure sensitive properties by a secondary structure superposed on the primary structure —**H P Robertson** On the foundations of relativistic cosmology A mathematical discussion leading to the view that the only possible cosmologies the intrinsic properties of which are independent of time are those of Einstein and de Sitter —**G I Lavin and Francis B Stewart** Production of hydroxyl by the water vapour discharge Excited hydroxyls are found in the discharge tube and destroyed in passing through the observation tube by some recombination reaction Intensity of the hydroxyl lines is parallel to the quantity of hydrogen peroxide found in the water condensed in the outlet trap —**Emma T R Williams** A spectrophotometric study of class *A* stars —**M Demerec** Genetic factors stimulating mutability of the miniature gamma wing character of *Drosophila virilis* —**Clyde E Keeler** (1) The occurrence of a heritable twisted nose in the house mouse, *Mus musculus* —(2) On the amount of external mirror imagery in double monsters and identical twins Mirrored features appear to be most frequent in laterally joined monsters —**S H Yarnell** Meiosis in a triploid *Fragaria* There appears to be complete pairing of non homologous chromosomes —**Karl Sax** Chromosome behaviour in *Sorbopyrus* and *Sorbaronia* Both these hybrids fruit freely, but the former sets very few seeds, cytological studies were carried out to determine chromosome compatibility and behaviour —**J C Walker, Karl Paul Link, and H R Angell** Chemical aspects of disease resistance in the onion *Colletotrichum circinans* (onion smudge) does not attack coloured varieties Black spots appear at harvest on the outer scales near the neck and, during curing and storage, the fungus penetrates the fleshy scales causing shrinking and decay A crude water extract from dry coloured scales is toxic to spores and also to thalli of the fungus Free protocatechuic acid (3, 4 dihydroxybenzoic acid) occurs in this extract —this establishes the free existence of this acid—and is one at least of the toxic agents involved —**Tracy Yerkes Thomas** On the existence of integrals of the system of partial differential equations $A^i_{\alpha\beta\gamma}=0$ in *n* variables —**Marston Morse** Closed extremals —**G A Miller** Non Abelian groups of odd prime power order which admit a maximal number of inverse correspondences in an automorphism

Diary of Societies

FRIDAY JANUARY 24

ASSOCIATION OF ECONOMIC BIOLOGISTS (Annual General Meeting) (at Imperial College of Science and Technology), at 4 30 —Dr Butler Some Aspects of the Morbid Anatomy of Plants (Presidential Address)

PHYSICAL SOCIETY (at Imperial College of Science) at 5 —J M Nuttall and E J Williams A Method of Examining Stereoscopic Photographs —S E Green *The Photography* of Fabry and Perot Interferometer Fringes by the Use of a Simple Optical System —Miss W A Leyshon Characteristic of Discharge Tubes under Flashing Conditions as Determined by the Use of a Cathode Ray Oscillograph —Demonstration by W E Dolan of a pH Apparatus

INSTITUTION OF ENGINEERING INSPECTION (at Royal Society of Arts) at 5 30 —J H Clarke The Anderson Rotary Piston Engine

INSTITUTION OF MECHANICAL ENGINEERS at 6 —E Watson Smyth General Operating Experiences with the first Wood Steam Generator

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Newcastle upon Tyne) at 6 —R A MacGregor Failure of Steel Forgings and Castings through Fatigue

INSTITUTION OF CHEMICAL ENGINEERS (at Institution of Civil Engineers), at 6 30 —Dr H Levinstein Films and Fibres derived from Cellulose (Lecture)

INSTITUTION OF LOCOMOTIVE ENGINEERS (London) (Manchester Centre) (at Literary and Philosophical Society Manchester) at 7 —J R Bazin Presidential Address

WEST OF SCOTLAND IRON AND STEEL INSTITUTE (at Royal Technical College Glasgow), at 7 —F Clerf Notes on Continental Blast-furnace Practice

MANCHESTER ASSOCIATION OF ENGINEERS (at Engineers Club, Manchester), at 7 15.—H C Lamb The Electrical Distribution System of Manchester

JUNIOR INSTITUTION OF ENGINEERS, at 7 30 —W J Rees *Refractories for Steam raising Furnaces*

LEICESTER TEXTILE SOCIETY (at Victoria Hall, Leicester), at 7 30 —F Willis Knitted Footwear

TEXTILE INSTITUTE (Lancashire Section) (at Harris Technical Institute, Preston) at 7 30 —J Starkie The Weaving of Artificial Silk

ROYAL SOCIETY OF MEDICINE (Epidemiology Section), at 8 —Dr G P Crowden Industrial Efficiency and Fatigue

ROYAL INSTITUTION OF GREAT BRITAIN, at 9 —Sir William Bragg Cellulose in the Light of the X Rays.

SATURDAY, JANUARY 25

ROYAL INSTITUTION OF GREAT BRITAIN, at 3 —Prof R W Chambers Sir Thomas More and His Friends (1)

BRITISH ASSOCIATION OF MANAGERS OF TEXTILE WORKS (at Manchester Athenæum), at 6 30 —F H Smith Foreign Yarn Business

INSTITUTE OF BRITISH FOUNDRYMEN (Lancashire Branch, Junior Section) (at College of Technology Manchester), at 7 —J O Gray Foundry Costing

MONDAY, JANUARY 27

INSTITUTE OF ACTUARIES at 5 —C H Wickens Australian Mortality

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 —Prof V Bonney The Surgical Treatment of Carcinoma of the Cervix

NORTHAMPTON ENGINEERING COLLEGE ENGINEERING SOCIETY, at 5 30 —G A V Sowter Realism from Records

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting) at 7 —G V Twiss High Tension Distribution

INSTITUTION OF ELECTRICAL ENGINEERS (North Eastern Section) (at Armstrong College Newcastle upon Tyne), at 7 —L C Grant The Breaking Performance of High Power Switchgear and of a New Form of Quenched Arc Switch

SOCIETY OF CHEMICAL INDUSTRY (Yorkshire Section) (at Great Northern Station Hotel, Leeds) at 7 15 —F A. Mason The Destruction of Materials by Micro organisms

KEIGHLEY TEXTILE SOCIETY (at Kiosk Café Keighley), at 7 30 —A Bennett Modern Improvements in Worsted Machinery

ROYAL SOCIETY OF ARTS at 8 —H J L Wright Three Master Etchers Rembrandt, Meryon Whistler (Cantor Lectures) (2)

ROYAL SOCIETY OF MEDICINE (Odontology Section), at 8.—Prof W Billington and H Round Bone Grafting and the Mandible Some Recent Results A Two stage Cleft Palate Operation

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall) at 8 30 —J M Wordie The Cambridge East Greenland Expedition 1929 Ascent of Petermann Peak

MEDICAL SOCIETY OF LONDON —Prof D P D Wilkie and others Discussion on The Etiology of Gall bladder Infections

ROYAL IRISH ACADEMY (at Dublin)

INSTITUTION OF THE RUBBER INDUSTRY (London and District Section) (at Engineers Club, Coventry Street, W C 2) —Hon F A Stockdale Lecture

TUESDAY, JANUARY 28.

ROYAL SOCIETY OF ARTS (Dominions and Colonies Meeting) at 4 30 —Sir Daniel Hall Settlers Problems in Kenya.

MANCHESTER UNIVERSITY CHEMICAL SOCIETY, at 5 —Dr W H Mills Some Stereochemical Problems

ROYAL SOCIETY OF MEDICINE (Medicine Section), at 5 —Dr A P Thomson (with Bacteriological Reports by Dr W T Hillier) Psittacosis —Dr O Layton Nine Cases of Recovery from Diabetes Mellitus

ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15 —Dr F W Aston Isotopes (2)

INSTITUTION OF CIVIL ENGINEERS at 6 —G Lacey Stable Channels in Alluvium

MANCHESTER ATHENÆUM TEXTILE SOCIETY (at Manchester Athenæum), at 7 —H P Curtis The Automatic Loom

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7 —J L Thomson The Technical Applications of X Ray Stereoscopy —R B Archey Photographic Emulsion Spots of Biological Origin

INSTITUTION OF AUTOMOBILE ENGINEERS (London Graduates Informal Meeting) (at Watergate House, Adelphi), at 7 25 —S C Vince and others Discussion on Tuning Motor Cycles for Speed

SHEFFIELD METALLURGICAL ASSOCIATION, at 7 30 —B S Smith Density of Molten Steel

WEST KENT SCIENTIFIC SOCIETY (at Wesleyan Hall, Blackheath Village), at 8.30.

LONDON CLINICAL SOCIETY (at London Temperance Hospital), at 8 45 —Dr A Hurst, H S Souttar, and others Discussion on The Treatment of Gastric Ulcer

WEDNESDAY, JANUARY 29

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 —Prof G E Gask A Contribution to the Treatment of Epithelioma of the Tongue by Radium

EUGENICS SOCIETY (at Royal Society) at 5.15 —E. J Lidbetter Insanity Legislation and Administration (Lecture).

INSTITUTION OF CIVIL ENGINEERS (Students Meeting), at 6 30 —A. H Kennard Highways, and a Survey of Future Developments

INSTITUTION OF ELECTRICAL ENGINEERS (South Midland Centre) (jointly with Midland Centres of Institutions of Civil and Mechanical Engineers) (at Midland Institute, Birmingham), at 7 —Capt P P Eckersley Broadcasting by Electric Waves (Faraday Lecture).

INSTITUTION OF AUTOMOBILE ENGINEERS (Graduates Meeting) (at Works of Austin Motor Co , Ltd , Northfield), at 7 30 —Prof W Morgan The Value of the Institution to its Junior Members.

HALIFAX TEXTILE SOCIETY (at White Swan Hotel, Halifax), at 7 30 —J P O Callaghan Water Softening for Industrial Purposes

ROYAL SOCIETY OF ARTS, at 8 —Sir Thomas H Holland International Movement of Mineral Products during Peace and War (Trueman Wood Lecture).

ROYAL PHILOSOPHICAL SOCIETY, GLASGOW (at 207 Bath Street, Glasgow), at 8 —Prof W E S. Turner Glass.

THURSDAY, JANUARY 30

ROYAL SOCIETY at 4 30 —R. H Salaman (a) Crinkle 'A —an Infectious Disease of the Potato (b) Paracrinkle—a Potato Disease of the Virus Group —E C Smith and T Moran The Formation of Lactic Acid in Desiccated Amphibian Muscles —H G Thornton The Influence of the Host Plant in Inducing Parasitism in Lucerne and Clover Nodules —*To be read in title only* —F Kidd and C West Physiology of Fruit 1 Changes in the Respiratory Activity of Apples during their Senescence at Different Temperatures —R. N Mukerji The 'Nuclear Reaction in Apanteles sp, with Special Reference to the Secondary Nuclei and the Germ Cell Determinant of the Egg

ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15 —Prof H A. Harris The Growth of Children in Health and Disease (2)

BEDSON CLUB (at Armstrong College, Newcastle upon Tyne), at 6 15 —Prof C K Ingold Tautomerism and Conjugation (Bedson Lecture).

INSTITUTION OF WELDING ENGINEERS (at Chamber of Commerce, Birmingham), at 7 —C A Hedley Modern Improvements in Electric Resistance Welding Machines

ROYAL SOCIETY OF MEDICINE (at Wellcome Historical Medical Museum), at 8 30 —Dr A P Cawadias From Epidaurus to Galen the Principal Currents of Greek Medical Thought —Demonstration by L W G Malcolm of Some Recent Acquisitions by the Museum

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (at Newport) —R. D Owen Chemical Fires, Causes and Prevention

FRIDAY JANUARY 31

ROYAL ASTRONOMICAL SOCIETY (Geophysical Discussion) at 4 30 —Seismic Methods in Surveying Prof A O Rankine, Dr H Jeffreys, Capt Shaw R S. Whipple, F J W Whipple Chairman Prof H H Turner

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 —Prof W S Handley The Papilloma and its Menace

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Graduate Section) (Joint Meeting) (at Newcastle upon Tyne), at 7 15 —W G Thompson The Electrical Propulsion of Ships

JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting) at 7 30 —F Onions Superheating

ROYAL INSTITUTION OF GREAT BRITAIN, at 9 —Lord Rayleigh Iridescent Colour in Nature

SOCIETY OF CHEMICAL INDUSTRY (Glasgow Section jointly with other Chemical Societies of Glasgow) (at Glasgow) —Prof I M Heilbron Lecture

INSTITUTION OF ELECTRICAL ENGINEERS (West Wales (Swansea) Sub Centre)

SATURDAY, FEBRUARY 1

MATHEMATICAL ASSOCIATION (London Branch) (at Bedford College for Women) at 3 —Annual Meeting

ROYAL INSTITUTION OF GREAT BRITAIN at 3 —Prof R W Chambers Sir Thomas More and his Friends (2)

ROYAL AERONAUTICAL SOCIETY (Yeovil Branch) (at Yeovil) —The Westland Wapiti in Service

PUBLIC LECTURES.

SATURDAY, JANUARY 25

HORNIMAN MUSEUM (Forest Hill), at 3 30 —H Harcourt Things Old and New from India s Treasury

MONDAY, JANUARY 27

UNIVERSITY OF LEEDS, at 5 15 —Prof R V Wheeler Pyrolysis of Hydrocarbons

UNIVERSITY COLLEGE, at 5 30 —Prof J Macmurray The Philosophical Approach to Modern Social Problems (Succeeding Lecture on Feb 10)

EAST ANGLIAN INSTITUTE OF AGRICULTURE (Chelmsford) at 7 —J G Stewart Farming Problems in East Anglia

WEDNESDAY, JANUARY 29

UNIVERSITY COLLEGE at 5 30 —Miss A S Cooke Recent County Library Developments

THURSDAY, JANUARY 30

KING S COLLEGE, at 5 30 —Prof R J S McDowall The Control of the Circulation (Succeeding Lectures on Feb 6, 13, and 20)

UNIVERSITY COLLEGE, at 5 30 —A D Lindsay The Relations between Ethics, Economics, and Politics (Jevons Memorial Lectures). (Succeeding Lectures on Feb 6 13, and 20)

SATURDAY, FEBRUARY 1

HORNIMAN MUSEUM (Forest Hill), at 3 30 —D Martin Roberts London in the Tudor Age

CONVENTION AND EXHIBITION

FRIDAY, JANUARY 31

ELECTROPLATERS AND DEPOSITORS TECHNICAL SOCIETY (at Northampton Institute, Clerkenwell)

At 2 —Convention, and Exhibition representative of Modern Scientific and Practical Advances in Electro Deposition

At 4 —Dr W Rosenhain Research and Practice

At 7 30 —Discussion on The Present Position of Chromium Plating.

SATURDAY, FEBRUARY 1, 1930

National Museums and Galleries.[1]

THE Royal Commission on National Museums and Galleries has completed its labours by the issue of Part 2 of the Final Report Appointed in July 1927, the Commissioners were given the task of reporting on the administration, buildings, cost, and indeed every phase of the activities of twenty institutions containing national collections situated in London and Edinburgh An Interim Report was published in September 1928, and the Final Report testifies to the satisfaction which the Commissioners felt in the endorsement of their first recommendations by the Government and by public opinion The final reports are models of clarity, and bear in mind the national need for economy in the public services, differentiating between what is immediately necessary and what is desirable Above all, the reports are practical, so far as possible avoiding ideas of change in the governance and methods of the national institutions, provided that they have worked reasonably well in the past Since many recommendations may be put into effect by the authorities of the institutions concerned, we trust that they will at once receive the closest attention, for there is little doubt that the Commission has accurately expressed leading representative opinion

In the present report the museums and galleries of Great Britain are considered in turn Their sixteen governing authorities are not to be altered seriously, this being the natural consequence in the previous report of the recommendation of a Stand ing Commission charged with the duty of securing co ordination and reviewing estimates The govern ance of the British Museum is a pseudo hereditary or hierarchic matter, and this is likely to give as high an average of intelligence as could be obtained by any other methods The power in any event is mainly in the hands of the 'elected trustees', and after all it is difficult to imagine a more impartial electing body than the Archbishop of Canterbury, the Lord Chancellor, and the Speaker of the House of Commons, who themselves are largely selected for their power of judgment of men

While it may be admitted that practising scien tific men are not always the best acquainted with the needs of science, we think that they should not be wholly unrepresented in the 'elected trustees' These need not be appointed for life, and it is of vital importance in science to have representation

[1] Royal Commission on National Museums and Galleries Final Report, Part II Conclusions and Recommendations relating to Individ dual Institutions Dated 1st January 1930 (Cmd. 3463) (London H.M Stationery Office, 1930) 2s net.

of the younger generations, since each science revolutionises its immediate aims about every twenty years The Natural History Museum is a vital unit in the science of biology, and its future position and usefulness depend on the due fitting of its wheel with many others, most of which are perhaps represented solely in research institutions and universities Of such bodies we would not advocate any direct representation, but the payment of due regard to the lines along which biology is advancing, by the selection as trustees of men active and distinguished in research and administration, is a matter which scarcely requires argument

The Director of the Natural History Museum, as has been proposed by all committees of inquiry, is to be made "wholly responsible for the care and custody of the collections housed therein" The Commission points out that this would require a short Act of Parliament, and, being clearly doubtful of the fate of its recommendation, suggests that the Director at once be given direct access to the Treasury in all matters affecting his museum We trust, however, that there is no doubt in this matter, and that the requisite steps may be taken to restore the original plan of the legislature, thus rectifying the organisation in accordance with the demand of practically all biologists As by Darwin and Huxley in the past, so by biologists to day, the independent responsibility of its Director is deemed to be essential for the development of the Natural History Museum in accordance with modern views

The Commissioners point out that such development will entail as a consequence that the Museum takes a more active part in expeditions abroad, since the mere collection of animals and plants for the sake of acquisition is of relatively small use compared with definite objectives in respect to particular problems An increased grant is recommended, and a staff adequate to the duties which it is called upon to perform Amongst these might be the attempt to increase the educational value of this institution, and a close study of the thoughts of the Commission as to the Science Museum might suggest several lines of evolution of great value

The need for a lecture theatre for these and other museums on the South Kensington site is endorsed, but it is suggested that, by arrangement, the new theatre of the Royal Geographical Society might satisfy present requirements This theatre will hold 1000 persons, and this is the maximum size proposed by the Commission It is not big enough for important meetings of the Society, and we think that, with the development of interest in science, a theatre of at least twice this size is essential, inviting alike the leading men in science and the educated mass in our metropolis It is essential to the contemplated increase of the Science Museum, so as to give full educational facilities, which is now recommended by the immediate erection of its central block

The question of the herbaria at the Natural History Museum and at Kew is faced The Commission has evidently given much time and thought to this question The members of Sir Michael Foster's committee in 1901, with one exception, were in favour of concentration at Kew The Commission endorses this as the ideal to be aimed at, but in view of the complications and difficulties to be met, refrains from making any definite recommendation It is suggested that if the combination could be effected, Great Britain would possess "a centre for botanical study which would be without a rival in the world" This raises a question as to the reasons for exhibiting botanical or indeed any preserved specimens at all in the Natural History Museum Beautiful and interesting plants and animals, with attractive labels, can teach much, and it might be advisable to retain and develop the exhibited series of plants at South Kensington for the instruction of the public, while relegating research collections to Kew Again, a possible division of plants (as into water and land forms, *sensu largo*) might perhaps be worth considering, or research on the algæ and fungi might be concentrated in the Museum Again, Kew is celebrated the world over for acclimatisation and horticulture, and the British Museum for its possession and knowledge of type specimens, possibly a correlation would be useful which emphasised these characters

The chief reason against the concentration of the botanical type collections in one place is the capital expense entailed, but this does not apply to the Geological Museum and Survey, the ground for the new building of which is now being cleared close to the Geological and Mineralogical wing of the Natural History Museum The Geological Museum is 'a research institution', but it is not to be treated as such since one of the best sites in the metropolis is assigned to it and a large part of its building is designed for exhibition It interdigitates with the biological side of geology, the central institution for which is the Natural History Museum The latter in its mineralogical division also possesses collections of great beauty and of high importance,

which obviously in their present surroundings can never receive the consideration they demand or attain the popularity they deserve We are surprised to see in the report no specific reference to them, since their present position is a matter of common discussion, and if they were suitably housed the space they occupy would be immediately utilised for other purposes As the Natural History Museum must extend its energies into the field, and as its exhibited series depends on research, we dislike the differentiation implied above in the term 'a research institution' It is not too late for the two authorities concerned to review all the facts between themselves, and it might be economical to relieve the officers of the Geological Survey, who are chosen for research, from all responsibility for exhibition

The Commission concludes with observations on the adequacy and recruitment of the staffs of the national museums and galleries, but so diverse are the requirements that it can only offer some general considerations As in most scientific institutions, there is a deficiency in the clerical staff, so that there is a wastage of the energy of the senior officers, who are specialists The recruitment is under Civil Service rules, which are designed on the idea that a young man of a certain ability can be taught anything to a fair level This is so, but museums and galleries require certain sections of feeling and learning developed to a supreme degree, if their work is to be properly carried out Both taste in display and powers of research require characters which are not usually shown until beyond the normal age of recruitment An investigation of the whole matter is suggested, but we are doubtful whether this is likely to secure results of any importance Brief courses in universities may lead to a level of mediocrity, which may well be deplorable in its results

We would be inclined ourselves to suggest the general adoption by the national museums and galleries of the system of pension insurance now in vogue in most of our educational institutions Thereby the freest interchange would be possible in each section of learning, and inevitably the most suitable curators would gravitate towards the national institutions, upon which the schemes adopted in the provincial museums and galleries depend It would appear to us a natural step in the unity of learning and research, to promote which unity is the highest function of any university, society, or institution for the furtherance of knowledge The greatest of these may be the British Museum

Brighter Chemistry

At Home among the Atoms a First Book of Congenial Chemistry By Prof James Kendall Pp xv + 270 + 16 plates (London G Bell and Sons, Ltd, 1929) 7*s* 6*d* net

SOMEONE has spoken of chemistry as a science of symbols, and in a sense the allusion is apt, since a skilful system of symbolic representation has lightened the labours of the chemist as much as the wonderful decimal notation has shortened the processes of the mathematician The peculiar force of a paradox is therefore lent to the reflection that this prime clarifying influence of modern chemistry is a direct outcome of the obscurantism of medieval alchemy From very early times, indeed, chemistry has been closely bound up with symbolism and mysticism in ancient Egypt a knowledge of chemical secrets was the jealously guarded prerogative of priests and kings, and at a later day the "sons of Hermes" enmeshed their "precious pearls" of alchemy in a web of enigma, cryptogram, and obscure expression which maintained the high standard of unintelligibility of their patron's famous Smaragdine Table

Thus, in his "Cours de Chymie", published in 1675, Nicolas Lémery had ample reason to complain that "la plûpart des Auteurs qui ont parlé de la Chymie, en ont écrit avec tant d'obscurité, qu'ils semblent avoir fait leur possible pour n'être pas entendus" Lémery himself was so successful in stripping chemistry of its mysticism that he produced a comprehensive and intelligible text-book which may be read with pleasure even at the present day So the "Cours de Chymie", which for the first time presented the naissant science to the world in all its native simplicity, became literally a 'best seller' of the seventeenth and eighteenth centuries, it passed through numerous editions in various languages, and held its place as the authoritative work on chemistry until the time of Lavoisier

The epoch making "Traité élémentaire de Chimie", published in 1789, swept away the last remnants of mysticism, while Dalton's "New System of Chemical Philosophy" afforded an indication, some twenty years later, of the coming resurgence of symbolism in the cause of progress Since the birth of the atomic theory there have been innumerable works dealing with the rapidly expanding science from various points of view, and ranging in size and cost from the lordly and misnamed 'handbooks' of Beilstein and others to plebeian sixpenny primers Lemery, as we have

seen, presented his information in an attractive form He had, in the words of Hoefer, "le talent de décrire les choses les plus obscures et les plus arides avec une simplicité et une précision remarquables" Unfortunately, the same cannot be said of some of his successors, for, on the whole, chemical writers have become more formal and arid as knowledge has accumulated

In the early days of the atomic theory, however, popular expositors of the science were not wanting Among such writers we may well pause to pay a tribute to Jane Marcet and John Scoffern for how many contemporary students of chemistry have so much as heard their names! Jane Marcet's "Conversations on Chemistry" first appeared in 1805, and ran through many editions during the succeeding fifty years The text took the form of a conversation between a certain Mrs B and her two pupils, Caroline and Emily

"To confess the truth, Mrs B," says Caroline boldly, at the outset, "I am not disposed to form a very favourable idea of chemistry, nor do I expect to derive much entertainment from it I prefer the sciences which exhibit nature on a grand scale, to those that are confined to the minutiæ of petty details I grant, however, there may be entertaining experiments in chemistry, and should not dislike to try some of them the distilling, for instance, of lavender, or rose water "

In countering this frank avowal, Mrs B points out that Caroline's "want of taste" for chemistry is a consequence of her limited ideas "You confine the chemist's laboratory to the narrow precincts of the apothecary's and perfumer's shops, whilst it is subservient to an immense variety of other useful purposes Besides, my dear nature also has her laboratory, and there she is incessantly employed in chemical operations You are surprised, Caroline, but I assure you that the most wonderful and the most interesting phenomena of nature are almost all of them produced by chemical powers "

If modern ambition should feel disposed to mock such useful pioneering toil, it suffices to quote a passage from one of Faraday's letters

"Mrs Marcet was a good friend to me," he wrote to de la Rive, "as she must have been to many of the human race I entered the shop of a Book seller and book binder at the age of 13, in the year 1804, remained there eight years, and during the chief part of the time bound books Now it was in those books, in the hours after work, that I found the beginning of my philosophy There were two that especially helped me, the *Encyclopaedia Britannica*, from which I gained my first notions of electricity, and Mrs Marcet's *Conversations on Chemistry*, which gave me my foundation in that science You may imagine my delight when I came to know Mrs Marcet personally, how often I cast my thoughts backwards, delighting to connect the past and the present, how often, when sending a paper to her as a thank-offering, I thought of my first instructress, and such like thoughts will remain with me "

Scoffern's "Chemistry No Mystery", published in 1839, is one of the few scientific books containing illustrations by Cruikshank, who made great play in it with the effects of laughing gas and sulphuretted hydrogen The frontispiece, entitled 'Laughing Gas', has a truly Pickwickian motif "Some jumped over the tables and chairs, some were bent upon making speeches, some were very much inclined to fight, and one young gentleman persisted in an attempt to kiss the ladies" Moreover, the harrowing story of the lady "made beautifully white" with a preparation of the metal bismuth, who "took a bath in the Harrowgate waters, when her fair skin changed in an instant to the most jetty black", would have made a notable addition to the repertoire of Sam Weller In this entertaining and informative work, chemistry is ably expounded in a series of twenty one lectures The author's point of view is explained in the following remarks addressed to his "dear young friends" in the opening lecture

"You think", he says, "that young people cannot possibly engage themselves in the study of a science which has been cultivated by such great men as Sir Humphry Davy and Doctor Wollaston —this supposition is wrong I grant that the very highest order of intellect is often required to make a discovery, but when once made it may perhaps be rendered comprehensible to persons much younger than yourselves, and indeed I cannot think of any necessary portion of chemical science which does not admit of a very easy and agreeable exemplification"

Like his predecessor, Lémery, Scoffern practised what he preached

These were joyous days for the 'joyous science', for it was in the following year (1840) that Wohler, writing under the significant name of S C H Windler, published his pseudo serious contribution to Dumas' ideas on "Substitution and the Theory of Types" in *Liebigs Annalen der Chemie und Pharmacie* To S C H Windler's statement that "in the decolorising action of chlorine, there is a replacement of hydrogen by chlorine, and that the fabrics which are now bleached in England according to the laws of substitution preserve their

types ", the genial Liebig, entering into the fun, added in an editorial footnote, " I have just learnt that there are already in the London shops fabrics of spun chlorine, much sought after in the hospitals and preferred to all others for night caps, etc "

Later in the nineteenth century, chemical literature relapsed into a severe formalism, which has been relieved only during the last few years by the appearance of a number of treatises designed to meet the needs of the growing popular interest in chemistry The new movement towards a brighter chemistry has been borne along upon the wave of increasing interest in the human side of science, and has found its main expression among the English speaking communities of the world Prof Kendall s book is an excellent example of this new tendency in the exposition of scientific facts and principles Reducing, as he explains in his preface, the formal side of chemistry to a minimum throughout his treatment, Prof Kendall develops in a logical and systematic manner the meaning of substances, elements, atoms, and other fundamental chemical conceptions Having brought us by pleasant ways into the atomic Lilliput, he proceeds to put us " on really intimate terms " with such prominent Lilliputians as oxygen (' the working-girl—Heaven has already protected her '), hydro gen (" nice baby "), and chlorine (' gentlemen prefer blondes ') Later he conducts us around the apartment house of Mendelejeff Court, pausing *en route* to relate to his party the story of young Newlands and " the dear old Tories of the London Chemical Society "

On the first floor we meet the metals of the alkali family, on the second, we hear of radio-activity, discover that the alchemists were funda mentally right, and rewrite the constitution, on the third, we are told in an impressive stage whisper that " Al's here ! ', and eventually we wander out into the country and explore the in triguing mazes of Bohrville The whole itinerary is enlivened by interesting glimpses of the human and historical side of the subject (including, we are glad to note, a quotation from Mrs Marcet), while the dark places are unfailingly illuminated by flashes of humour, dashes of picturesque phrase-ology, and telling illustrations from the things and doings of everyday life, the book also contains numerous explanatory diagrams and plates " Read Sir John Mandeville's Travels to cure you ", was the advice of Charles Lamb the convalescent of a later and more scientific age may be recom mended to join in Prof Kendall's personally conducted tour among the genuine marvels of the atomic world

Up to the present, the revivification of chemical literature has not extended to the periodicals, and if we suggest that the circulation of any one of our standard chemical journals would increase by leaps and bounds if only every hundredth com munication were written by a modern S C H Windler, we may perhaps anticipate a reply from " the dear old Tories " in the sense of the concluding words of the excellent Scoffern " As a young lion torn from the forest is tame and playful, allowing caresses, and joining in every frolic, so we found chemistry, but as it grew up to its full size and strength, it became a thing no longer to be played with, demanding all care, attention, and respect "

JOHN READ

Prehistoric Art and Symbolism

Rock Paintings of Southern Andalusia a Description of a Neolithic and Copper Age Art Group By the Abbé Henri Breuil and M C Burkitt, with the collaboration of Sir Montagu Pollock Pp xii + 88 + 34 plates (Oxford Clarendon Press, London Oxford University Press, 1929) 63*s* net

THERE are already several important treatises on the Upper Palæolithic art in the caves of France and northern Spain There are also several memoirs on the peculiar art, probably of the same age, in the rock shelters of eastern Spain The subsequent development of this art, however, has not hitherto been exhaustively treated only a few scattered papers have shown that there is ample material for the purpose in the rock shelters of southern and south eastern Spain Since 1913, when the Abbé Breuil and Mr Miles Burkitt made some preliminary explorations and observations, the Abbe has devoted several seasons to the task of tracing all the more important examples of this later art and making notes in the field Sir Montagu Pollock has translated and edited the notes for publication, and Mr Burkitt has added some introductory and concluding general remarks. The result is a handsome volume, illustrated not only by photographs and text figures, but also by several coloured plates, of which two are due to the generosity of the Marquis of Bute

The art under consideration is definitely proved to be later than the Palæolithic art of eastern Spain, because it extends into the same area and is sometimes represented in the same rock shelters When the two sets of paintings are superposed,

those of the Palæolithic phase are underneath The later art, however, is not characteristically eastern it has been traced over the greater part of southern Spain, and its centre seems to be Andalusia It is expressed chiefly in small paintings made by using the oxides and carbonates of iron, probably mixed with fat which has disappeared, and it is preserved only in shelters which are dry There are very few engravings

The paintings, which are usually only a few centimetres in diameter, are of particular interest, because they are not naturalistic but reduced to conventional designs, often no more than symbols The human figure is especially common, and a female is often represented with clothing and head dress A form of deer is the only abundant mammal, and the multitude of birds is especially noteworthy When well preserved, as in the Cueva de las Figuras, in the south west of the Sierra Momia, the paintings are so numerous and conspicuous that they have long been known to the local people, who regard them as the handiwork of the Moors

The detailed descriptions and coloured illustra tions begin with the shelter or 'cave' of Las Figuras, in which there are more than five hundred separate paintings, not grouped into scenes Every noteworthy figure is mentioned and explained, and besides several photographs of these figures, there are also many beautiful photographs of the various shelters themselves and the country surrounding them The whole forms a most valuable work of reference for the student, who may draw his own conclusions, and will be grateful for the guidance afforded by Sir Montagu Pollock's introductory note In this note, series of conventional paintings of the human figure are collected, to show how the recognisable outline may degenerate into a symbol which would be inexplicable if the successive gradations were not forthcoming In one series, a man passes into something like a Greek ϕ, in another to a cross, in a third to a star A multi plication of the arms (as in the case of certain Indian deities) produces a still stranger ultimate figure A deer, by the multiplication of the legs and the loss of the head and neck, passes into something like a comb The beginning of symbolism is indeed most evident

The authors suppose that some of the paintings are considerably older than the others, and suggest the possibility that there is a connexion between the earliest of them and the markings on the well known Azilian painted pebbles Mr Burkitt, however, compares the paintings of the deer and some of the symbols with similar ornament on Spanish pottery which certainly belongs to the Copper Age If the comparison be justified, most of the art now described is thus either Neolithic or slightly later This conclusion is so interesting, that archæologists will eagerly await further developments of the research A S W

Measurement of Animal Environment

Laboratory and Field Ecology the Responses of Animals as Indicators of Correct Working Methods By Prof Victor E Shelford Pp xii + 608 (London Baillière, Tindall and Cox, 1929) 45s net

PROF SHELFORD is one of the best known American students of animal ecology It will be remembered that, more than twenty years ago, he published a number of studies on the relations between the larvæ of tiger beetles and the soil and vegetation on the shores of lakes near Chicago, and that more recently he and his associates have been concerned in the study of the relation between the codlin moth and climate From field work of this type he has progressed in the direction of controlled work in the laboratory He has not tried to study the animals as a physiologist would, by isolating factors and devising 'good experiments' in which one factor only is allowed to vary On the contrary, he holds that the ecologist in his laboratory should aim at reproducing the complex, varying, cyclic conditions of Nature This is a legitimate view, but it is not in accordance with the general scientific maxim that work should proceed from the analysis of simple controlled experiments to the synthesis of more complicated conditions Parts of Prof Shelford's book describe the extremely complex and expensive plant, designed to give complete control of temperature, atmospheric humidity, and other factors, and to provide a great variety of combinations of them

We have found it difficult to know where the line should be drawn between ecology, physiology, and other clearly defined sciences, and some of the contents of the book under notice are unexpected On the other hand, there are some omissions which we may be permitted to point out If the index may be trusted, there is no mention of the katathermometer in spite of its recognised value in relating climatic conditions to the life of warm-blooded animals, moreover, the same instrument can be employed to measure currents of air under conditions which prevent the use of most types of anemometer Prof A C Hardy's plankton recorder

should also find a place in the book The account of the methods and results of marking migratory birds with metal bands makes no mention of what has been done in Europe this one regrets, for much work done in Britain, Germany, and other European countries has been very thoroughly carried out and summarised The list of references at the end of the book will be of great value As it does not attempt to approach completion, one can scarcely criticise the omissions, but it is noticed that comparatively few references in French or German are included Surely Mr Elton's excellent Animal Ecology " should be among the works to which the student is referred

Those parts of the book which deal with climate and its effect on animals have interested us particularly, and we find two omissions which appear to be noteworthy There is a full discussion of the relations between animals and humidity, and on the complication which is introduced by temperature, but there appears to be no allusion to the essential fact that humidity measured as relative humidity has very little biological meaning yet we know already that it is saturation deficiency which is of importance in the physiology of mammals and of plants The distinction between saturation deficiency, absolute humidity, and relative humidity is one that is appreciated by very few biologists, and had Prof Shelford stated it clearly (and possibly represented it graphically) we should have been very much in his debt

We should also like to see it recognised by ecologists that solar radiation of one type or another is the most important part of climate for plant or animal it is the least understood and studied, because meteorologists concern themselves so much with barometric pressure and the dynamics of the atmosphere In reading the section on solar radiation we discovered a curious error repeated several times it is stated that black bulbed thermometers are used for recording the intensity of *light*

The book contains a mass of information on a number of subjects We know none other which covers the same ground, and it will be continually used for reference, for its particular value lies in the descriptions of methods and apparatus It gives less attention to field ecology, and does not show the living animal set in a complex environment of climate and soil, living enemy and competitor When a second edition is called for, we hope the index will be much fuller The contents of the book are so essentially promiscuous that a full index is more than usually necessary

P A BUXTON

Fossil Plants from the Coal Measures

Coal Measure Plants By Dr R Crookall Pp 80+40 plates (London Edward Arnold and Co, 1929) 12*s* 6*d* net

THE study of British Carboniferous plants will be stimulated and advanced by Dr R Crookall's book Dr Crookall is palæobotanist to the Geological Survey of Great Britain and is also in charge of the splendid collection of Palæozoic plants made by the late Dr R Kidston, he is therefore in a position to speak with authority on Carboniferous plants The book, however, is not written primarily for the specialist or the botanist, and will recommend itself as an introduction to the subject to geologists who have had no botanical training, to amateurs, and to field naturalists It will also be of value as a book of reference for university students in connexion with courses on the Pteridophyta and Gymnosperms

The great advances in palæobotanical research made in the last century in Britain were due very largely to the enterprise of amateurs, among whom may be mentioned that group of Lancastrians, some of whom were working men, whose discoveries of 'petrifactions' of plants in the coal seams were described by Binney and Williamson Kidston was responsible for practically all the important work on Carboniferous plant 'impressions' and he received very considerable assistance from other amateur collectors, as well as from the Geological Survey, to which he acted as honorary palæobotanist But active amateur interest in fossil plants has almost disappeared in the last few decades, probably partly as a result of the complicated terrors of nomenclature and the consequent difficulty of identifying specimens Dr Crookall's book, with its clear descriptions and excellent half-tone illustrations, will help to remove this disability

In many parts of Great Britain the countryside is disfigured with waste tips from collieries, but these afford some compensation by offering a great opportunity to the student of fossil plants The shales and sandstones brought up from the workings of the mines contain abundant examples of mummified plants, which, with the help of such a book as "Coal Measure Plants", may become intelligible to the non specialist

Dr Crookall in the introductory chapter describes the nature and origin of plant fossils, with a brief account of the stratigraphy of the Coal Measures and a general review of the main divisions

of the plant kingdom encountered in them Six chapters are devoted to the detailed description of these divisions, with valuable notes on the identification of the important species, and are fully illustrated in the thirty-nine plates Kidston divided the Coal Measures, on the basis of the plants found in them, into four principal zones, each characterised by certain species and the relative abundance of others, and in the last chapter lists are given of the species characteristic of these zones In a short appendix some valuable practical advice is given to collectors A full list of the species described, with the names of their authors and an adequate index, completes the letterpress of the book

The main object the author has in view is to facilitate the identification of specimens, and he will have achieved this partly by the descriptive chapters, but mainly by the large number of plates containing illustrations of two hundred and forty species The photographs, which fill twenty one of the plates, are excellent The other plates, containing line drawings, which are used by the author to indicate distinctions between species, are on the whole good, but a few of the drawings are unnecessarily crude, and while quite effective for purposes of identification, are somewhat unsightly

We may congratulate Dr Crookall on having produced a clear and well illustrated guide to the study of fossil plants from the Coal Measures

The Design of Scientific Instruments

The Kinematical Design of Couplings in Instrument Mechanisms By Prof A F C Pollard Pp 64 (London Adam Hilger, Ltd, 1929) 4*s* 6*d* net

PROF POLLARD'S monograph is a clearly written and well illustrated little book urging the application of kinematical principles in all instrument design The basis of his book is the well-known theorem that a rigid body has six degrees of freedom, any number of which can be annulled by an equal number of suitable kinematical constraints, neither more nor less This singleness of purpose, together with the author's attractive manner of writing, have combined to produce a concise and readable book, which should be closely studied by all instrument designers who are not already acquainted with the principles advocated Not the least valuable part of the book to the designer are the well-chosen examples of correctly designed instruments, which occupy actually the greater part of the book The descriptions and illustrations of these leave nothing to be desired

Prof Pollard censures the 'machine tool' type of design severely, and with certain reservations we are in full agreement with him It frequently happens in practical designing that one is reluctantly forced to abandon some kinematically correct feature on account of other considerations, such as wear of the parts or prohibitive contact stresses An example of this may be taken from the book itself A knife edge pivot is described, which is quite a beautiful example of kinematic perfection, in which the four necessary constraints are supplied by four steel spheres in contact with the edge Yet this perfect device is not applied in our balances, presumably because of the excessive elastic deformation which would occur at the four point contacts Instead of this, the modern balance flagrantly violates kinematical principles, which have to be subservient to other considerations, such as sensitivity and durability In such cases, as the author clearly explains, only perfection of workmanship can compensate, and the book strongly emphasises the sound procedure of commencing every design on kinematical principles, and only falling back on accurate machining when absolutely necessary

In the important class of movements having one degree of freedom, such as a sliding or a rotating member, the author strongly advocates the use of commercial steel balls Where instruments of high precision are concerned, it would seem well to caution designers to employ only balls which will pass a three point test for sphericity In most applications the ball is actually in contact with three different surfaces, whereas it is manufactured by a process which ensures uniformity of diameter as measured between two parallel planes, but does not necessarily produce true sphericity

In one place we should differ completely from the author, where he recommends 'Staybrite' steel as superior to hardened and ground steel, in that it does not require hardening This special non-rusting steel is in fact incapable of being hardened, except to some extent by cold working, and could not well take the place of hardened steel where hardness is the essential property The book, however, is not concerned with the materials of instrument design so much as with the principles, and its value to the designer is in no way reduced by the small point on which we have commented

Our Bookshelf.

Thyroxine By Dr Edward C Kendall (American Chemical Society Monograph Series, No 47) Pp 265 (New York The Chemical Catalog Co, Inc, 1929) 5 50 dollars

THE researches of Prof Kendall into the chemistry of the active principle of the thyroid gland are well known this monograph, however, is much more than an account of his own work, since the study of thyroxine implies the study of the physiology of the thyroid gland The viewpoint is that of the chemist who is concerned with the relationship of thyroxine to the processes of oxidation in the animal body

Although Kendall isolated the active principle in crystalline form in 1914, it was not until 1926 that Harington and Barger proved its constitution by synthesis As a result of his original analyses, Kendall had found that thyroxine contained three atoms of iodine, whereas actually four atoms are present the explanation of the discrepancy appears to be that volatilisation of traces of organically bound iodine occurred during the alkaline fusion of thyroxine, so that the molecular weight assigned was too low

Thyroxine is not the only iodine compound present in the thyroid gland Harington (*Biochem J*, vol 23, p 373, 1929) has recently isolated diiodo tyrosine and considers that only these two are present, Kendall, however, inclines to the view that thyroxine may exist in the gland in an 'active' form, since dried thyroid may have quantitatively somewhat greater activity than thyroxine, and also that other compounds are present He describes also the activities of the various substances which have been isolated from the gland and reviews the evidence on its physiological function in this connexion he refers to the clinical disorders of this functioning, in so far as they throw light on the influence of the active principle upon the chemical activities of the body This book should be in the hands of all biochemists, physiologists, and pharmacologists it will be invaluable as a work of reference, since more than five hundred papers are reviewed in the text

(1) *Youth the Psychology of Adolescence and its Bearing on the Reorganisation of Adolescent Education* By Prof Olive A Wheeler Pp xv + 202 (London University of London Press, Ltd, 1929) 5s net

(2) *The Child from Five to Ten Interests and Problems of Early Childhood* By Evelyn and Miriam Kenwrick Pp vii + 299 (London Kegan Paul and Co, Ltd, 1929) 7s 6d net

WE place these two books in juxtaposition because together they constitute a sign of the times In certain respects they differ markedly Dr Olive Wheeler's treatment of her theme is emphatically scientific, whilst the Misses Kenwrick are strong in human sympathy and in practical insight This is by no means to say, however, that Dr Wheeler is not human, or that the Misses Kenwrick are not scientific Each writer gives of her best, and her best is very good

(1) Dr Wheeler has chosen the more familiar ground, for the psychology of adolescence has a considerable literature of its own But besides giving us a more manageable book than Stanley Hall's, and a more adequate one than Dr Slaughter's, she has brought her account abreast of recent inquiry, including work of her own, and has thought out her subject in connexion with the questions of educational reorganisation that confront England at the present time "Youth" is both an able and a timely book

(2) In a sense the Misses Kenwrick break new ground, for the period between infancy and adolescence has not received so much attention from psychologists as those two periods, the one so full of charm, and the other so full of peril But the child from five to ten, or at any rate from seven to eleven, is destined to become a definite educational problem by himself, so we welcome this book The writers owe nothing to the method of the questionnaire, or to any studies on the extensive scale But their keen insight, their experience as teachers, and their adequate psychological equipment, have enabled them to give us valuable intensive studies of individual children

An Historical Catalogue of Surrey Maps By Henry A Sharp Pp 56 (Croydon The Central Library, 1929) 3s 6d net

THIS is a handy catalogue of those maps of Surrey which find a place in the Croydon Public Libraries The list is arranged in chronological order, and the first entry of an original map is Peter Keer's map of Surrey of 1599, published by Speed We then find entries of maps by Norden, Speed (engraved by Jodocus Hondius), in many forms, Blaeu (1648), Jansson, Blome (engraved by Hollar), Morden (1695), Seller, "Surrey actually survey'd and delineated" (1733), Rocque, on the large scale of 2 inches to the mile (1762), until we come to John Cary (1754–1835), and the beginning of the more modern type of map There are altogether 176 different maps or editions tabulated and described, and the work has evidently been a labour of love for the author

There is an excellent introduction in which the reader will find a great deal of information about the maps of Surrey, and some other matters, such as the story of Mr Smyth and his Dog A useful addition in any future issue would be some information as to the amount and value of the original field work which forms the basis of the maps, some account, for example, of Saxton's actual surveys Saxton was born about 1542, and he has been called the first English cartographer Keer reduced his maps from Saxton, but it was Saxton who did the field work Some description of Cary's actual surveys would be of value, and generally, it would be of interest to discriminate between those cartographers who used new material, and those who merely made a re hash of previously existing maps

It might be as well, in future editions of this catalogue, to rearrange the entries relating to the Ordnance Survey 1 inch maps The present arrangement is not perfectly systematic

Problems of Neurosis a Book of Case Histories By Alfred Adler With a Prefatory Essay by Dr F G Crookshank Edited by Philippe Mairet Pp xxxvii + 178 (London Kegan Paul and Co , Ltd , 1929) 8s 6d net

THE number of books in English on Alfred Adler's contributions to psychology grows, and the present volume is certainly not the least interesting of them. The principles and practices of 'individual psychology' are exemplified by a number of case histories The book thus resembles "The Case of Miss R", which appeared in an English translation some time ago, but it is more comprehensive

We are strongly inclined to think that anyone desiring a clear introduction to Adler's way of thinking will do better to begin with "Problems of Neurosis" than with the more formal treatment to be found in other books They will also realise that, like Freud, he gives a doctor's rather than a teacher's psychology, although no hard and fast distinction can be drawn between the two This view is strengthened by the fact that Dr Crookshank, a medical man, introduces the reader to Adler's text In doing so he gives a clear and helpful account of the individual psychology

The convinced Freudian may continue to assume the dominance of the sexual factor in, let us say, the interpretation of dreams Others, and we believe a majority of students of psycho analytic literature, will agree with Adler that the sexual factor is determined by the goal of superiority We think that this book strengthens Adler's position, and at the same time makes a very readable addition to the literature of the subject

Descriptive Sociology or, Groups of Sociological Facts, Classified and Arranged by Herbert Spencer No 13 *Mesopotamia (The Ancient Inhabitants of the Tigris Euphrates Lands)* Compiled and Abstracted upon the plan organised by Herbert Spencer, by Reuben Levy Issued by Mr Spencer's Trustees (T W Hill, Editor) Pp iv + 49 + 4 tables (London Williams and Norgate, Ltd , 1929) 42s net

THIS wonderful collection of snippets goes on as before The compiler's industry and the trustees' funds would appear to be practically wasted in the preparation of a commonplace book for the late Mr Spencer, who is not here to consult it Under the heading "General Government Hittites" there is this and nothing more "*Taxation* The man who is given absolute possession of landed property must pay a tax on them" (whom ?) If the possession "is only partial, he need pay no tax (*A O*, xx p 11)" How helpful in dealing 'sociologically' with Income Tax Schedule A how futile, otherwise ! J L M

Glue and Gelatine By Paul I Smith Pp x + 162 (London Sir Isaac Pitman and Sons, Ltd , 1929) 8s 6d net

THE author's general survey of the subject, given within a modest compass, should be of interest and use to the technologist and manufacturer The book includes a consideration of the raw materials used in preparing glue, gelatine, and isinglass , the preservation of stock by the glue manufacturer , the plant used in filtration, evaporation, and other general operations , the analysis and uses of glue and gelatine together with some historical notes

The chapter on the chemistry of proteins needs careful revision In the note on amino acids (p 21) the prefixes α and β should be interchanged , the structure attributed to alanine is incorrect , and the representation of the primary amino group may convey the idea that it is bivalent Esters are misrepresented in the first two structural formulæ on p 24 , on p 30 leucine is termed "lencin", and its molecule is credited with a primary amino group attached directly to a carboxyl group ! Another quinquevalent carbon atom is represented on p 138 Comment is also invited by the use of such expressions as "a strata" (p 39) and "good quality glue" (p 54) The book is well printed, and it contains some interesting illustrations

Creation by Evolution a Consensus of Present day Knowledge as set forth by Leading Authorities in Non technical Language that all may Understand Edited by Frances Mason Pp xx + 392 + 22 plates (New York The Macmillan Co , 1928) 21s net

THERE is much to be said for the method adopted by the editor of associating short essays on different aspects of evolution, each written by a specialist, as a body of evidence designed to appeal to the general reader If there is bound to be a certain amount of repetition, as when the recapitulation theory or the origin of birds from reptilian stock is discussed by different authors, or a certain amount of inconsistency, as, say, in the attitude adopted towards 'species', these weaknesses are more than atoned for by the variety of style and outlook of the individual contributions The editor has been fortunate in obtaining as witnesses to the reality of evolution some of the best known biologists in Great Britain and the United States, and the twenty six essays, which cover an extraordinarily wide and interesting field, are marked by a simplicity of statement (and occasional dogmatism) which will appeal to the plain man

Lehrbuch der Geophysik Herausgegeben von Prof Dr B Gutenberg Lieferung 5 (Schluss) Pp xx + 797 1017 (Berlin Gebrüder Borntraeger, 1929) 18 gold marks

THE fifth and last part of Gutenberg's "Lehrbuch der Geophysik" has now appeared Most of it deals with meteorology, and is by Dr L Weickmann The chief instruments are described, and most of the existing theoretical work is outlined The result is a handy book, with copious references to original papers, which has long been needed There are some curious omissions , for example, the chapter on atmospheric friction does not contain the name of G I Taylor or of L F Richardson The perfect book on dynamical meteorology will not, however, be written for some time, and meanwhile Weickmann's work is a useful approximation H J

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

Early Rhodesian Gold

I HAVE not the intention of entering into the correspondence which I hope to see develop further out of Prof J W Gregory's letters in NATURE of Nov 9 and Jan 11 If, however, that correspondence is to be profitable to science and clear thinking, may I ask that precise information be given on certain points which have been once more resurrected ? For example

(a) *Roman Coin from Umtali* —Who found it ? Who has seen it ? What were its associations when found ? I made inquiries of course, in Rhodesia, but even the late Mr R N Hall had, it seems, given up faith in it The history of other coins of antiquity purporting to be South African finds is, when investigated, no more satisfactory See Prof Dart's article, NATURE, Mar 21, 1925, and Mr Schofield's devastating retort, Mar 27, 1926

(b) *Soapstone Birds on Beams* —What parallels sufficiently close to pass morphological muster are provided by ancient Egypt and Assyria ? Who has published them ? For one would wish, when these birds come to London in the spring for temporary exhibition at the British Museum, to place their counterparts beside them for comparison This I shall also hope to see done with the ' Rosette ' Cylinder

(c) *Ptolemaic Beads* —Who ' referred ' them to this source ? I am of course, acquainted with Bent's reference He says ("Ruined Cities of Mashonaland", p 204), "beads of doubtful provenance, though one of them may be considered as Egyptian of the Ptolemaic period " They were found ' in the vicinity of the Temple " very near the surface What were their associations ? Celadon, Arab glass, and Persian ware Deposits, like ladies, have the fortune to be dated by their youngest feature

(d) *Proto Arabic Inscription* —Where was it found and where published ? Bent published ("Ruined Cities of Mashonaland", p 199) an ' inscription ' on a soapstone bowl, and supposed letters on a rock in Bechuanaland These were elaborated by Keane, with the result recorded in the *Geographical Journal*, April 1906, p 346 I have looked at all the bowls in museums but could not identify Bent's inscription The soapstone bowl fragments we found are a mass of scratches

Further why is that nice eighteenth dynasty Ushabti figure from Ndanga always left out of the argument ? Its value as ' evidence ' is not less remarkable than that of the other relics mentioned

Two more questions (1) When mining authorities of eminence differ in their estimate of the gold production by £60,000,000 (maximum £75,000,000, minimum £15,000,000), what is the archæologist to do ? I can only suggest that he should read Theal's "Records" carefully, and examine the relics from ' ancient workings ' at Bulawayo and Salisbury (2) When a coin of Antoninus Pius is found in a mine shaft at Umtali and is considered to date that mine, why should not four Bantu skeletons found *in* ancient mines be taken equally as evidence ?

So far as space has hitherto allowed, I have put the plain facts of excavation on the table, these facts are now being dealt with fully in book form, which I hope may be available by the summer It is fair, therefore, that I, too, should be given facts, so that I may take them into full consideration Theory I have had offered to me, and generalisations without number But facts can only be met by facts Who will supply them ?

Colours of Inorganic Salts

No satisfactory explanation of the colours of inorganic salts in the vapour state, in solution, or in crystalline form has yet been put forward, excepting certain suggestions by Fajans ("Handbuch der Physik", Bd 24, p 564), that the colours are due to the deformation of the cation produced by surrounding anions and molecular complexes The ideas of Fajans were rather vague, but the time has now come to put forward a more precise hypothesis It is well known that salts like NaCl, $CaCl_2$, $AlCl_3$, in which the electrons of the cation form closed shells (p^6), are colourless or white Herzfeld found from a study of dispersion of NaCl that there are three ultra violet absorption bands, one at λ340 which was ascribed to Na^+, another at about λ1500, which was ascribed to Cl^- ion This last one has been experimentally obtained by Pfund (*Phys Rev* vol 32) by the *Reststrahlen* method The wave length λ340 ascribed to Na^+ agrees remarkably well with the resonance line of Na^+ identified by K Majumdar (*Ind Jour Phys*, 1927) and Bowen, though definite assignment of values of the absorption wave length from dispersion data in this region is subject to certain uncertainties

Colours are almost entirely shown by the compounds of the transitional group of elements (the first group consisting of elements from scandium to copper) Let us fix our attention on the first group alone, as the same arguments will apply to other groups The colours are somewhat modified by the anion, or the state of aggregation (solution or crystal), but intrinsically it is due to the cation Taking a compound like $CrCl_3$, we can say that it consists of a Cr^{+++} ion, surrounded by three Cl^- ions The absorption of light in the visible region is due entirely to the outer electrons of the Cr^{+++} ion Let us see how this absorption takes place

The outermost shell of the Cr^{+++} ion (and generally of all ions of transitional elements) consists of a number of electrons in the d shell In Cr^{+++}, the number is 3 The multiplicity of the most stable combination state is obtained by adding up the multiplicity vector $r = \frac{1}{2}$ for all the electrons, and the next metastable states are obtained by reversing the vector r for one of the electrons In d^3, the states are respectively ^4X and ^2Y, where X and Y are further to be formulated This is obtained by considering the l coupling according to Pauli's principle, and in the case of Cr^{+++}, $X = F$ and P in ^4X, and $Y = H, G, D$ in ^2Y The average difference in energy between the terms obtained in this way, that is, by having the rotating quantum number all in one direction, and then reversing only one, is about Ca, = 20,000, the value increasing with the number of net charges in the nucleus, as shown by the spectroscopic data of Russell, Gibbs and White, Lang, Shenstone, etc (see various papers in the *Physical Review*)

It is therefore evident that the absorption of light in the visible region is due to some of the d electrons changing their r vector from $\frac{1}{2}$ to $-\frac{1}{2}$ This type of transition is possible only in transitional groups, and though usually forbidden they become very prominent in all molecular formations We cannot, of course, expect that the values of energy difference which we

obtain from spectroscopic studies will continue to hold good in molecules or complex formation, but they will remain of the same order of magnitude An indefiniteness will be introduced by the modification of the rules of l-coupling (*vide* Stoner's suggestive paper in the *Phil Mag*, September 1929, which explains D M Bose's hypothesis that it is only the rotating vector r which is responsible for the magnetism of the ions of transitional elements in a similar way)

There seems to be no experimental evidence in existence which can be utilised in support of the above hypothesis The absorption spectra of none of these compounds have been studied in the vapour state (the work of Franck and his school being confined mostly to the study of alkali halogenides) The emission spectra of some of these salts have been studied, but it is difficult to draw any conclusion from them Other interesting experiments may also be devised to test the above hypothesis Some of them are in progress

The Heat of Dissociation of the Molecule O_4 and Sutherland's Constant for Oxygen

THE law of interaction of two colliding molecules follows the curve shown in Fig 1, where the mutual potential energy U of the molecules is plotted against the distance r between their nuclei In the case of molecules with saturated bonds, U is determined by the polarisation forces and repulsive forces, the nature of which we do not propose to discuss here When the chemical bonds are unsaturated, the 'chemical forces' (*Austauscheffekt*) also must be taken into account In both cases the energy minimum (U_0) corresponds to a definite stationary state of the

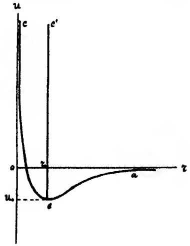

FIG 1

associated molecule Such a twin will appear if the molecules lose during the collision a certain amount of their energy, for example by means of a triple collision, so that the total energy attains a negative value The dissociation energy W of this twin is equal to $-U_0$ (Fig 1)

In the kinetic theory of gases, the molecules are regarded as perfectly elastic rigid balls, and the real curve *abc* is replaced accordingly by the curve *abc'* In this case the mutual energy of two molecules at the moment of collision must be equal to $-U_0$ We propose to show that this energy is nothing else than Sutherland's constant, which determines the dependence of the effective area of the molecule on the temperature

Owing to the polarisation forces, the effective area for the collision of molecules increases, as may be seen from Fig 2 The molecule 2, in the absence of

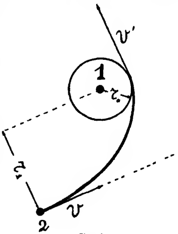

FIG 2

the attractive forces, would move in the direction of the dotted line without undergoing a collision with the molecule 1 But the attractive forces will draw the molecule away from the straight line path and a collision may occur The less the relative velocity of molecules 1 and 2, the greater will be the aim distance r_1, at which a collision still occurs Let us find now the connexion between r_1 and r_0 From the equations expressing the laws of conservation of energy and moment of momentum, namely,

$$\frac{mv^2}{2} = \frac{mv'^2}{2} - W \quad \text{and} \quad mvr_1 = mv'r_0,$$

where m is the effective mass of the molecules, v and v' are the relative velocities before and at the moment of collision respectively ($v'>v$), we obtain

$$\frac{mv^2}{2} = \frac{mv^2}{2}\left(\frac{r_1}{r_0}\right)^2 - W,$$

or, introducing real and effective target areas of the molecules (σ_0 and σ_1),

$$\sigma_1 = \sigma_0\left(1 + \frac{W}{mv^2/2}\right) \qquad (1)$$

This is valid for a single collision In order to calculate the mean value of σ_1 (for the gas as a whole) we must average the expression (1) We have

$$\frac{1}{mv^2/2} = \frac{2}{kT},$$

and therefore

$$\bar{\sigma}_1 = \sigma_0\left(1 + \frac{2W}{kT}\right) = \sigma_0\left(1 + \frac{2D}{RT}\right),$$

where D is the molar heat of dissociation Comparing this expression with Sutherland's formula,

$$\bar{\sigma}_1 = \sigma_0\left(1 + \frac{C}{T}\right),$$

we get

$$D = \frac{R}{2}C, \text{ or approximately}$$
$$D \simeq C \text{ cal} \qquad (2)$$

(The calculated ratio D/C depends on the way in which the averaging is done; see, for example, Condon and van Amunge, *Phil Mag*, **3**, 604; 1927. However, the order of magnitude of this ratio always remains the same.)

Unfortunately, the failure of the experimental data on the heats of dissociation of twin molecules and Sutherland's constant makes it impossible to prove the correlation (2) in many examples. The values of D and C simultaneously are known only in the case of oxygen. Thus, in order to explain the fact that the oxygen does not obey Curie's law, Lewis (*Jour Amer Chem Soc*, **46**, 2027; 1924) assumed that in liquid oxygen as well as in oxygen gas, the molecules O_2 are associated to some extent into O_4. Using data of Perrier and Kamerlingh Onnes for the magnetic susceptibility of oxygen at various temperatures, he estimated the molar heat of dissociation of O_4 into $2O_2$ to be about 128 cal (for liquid oxygen). There are some grounds for regarding this value as approximately correct for the gas. The existence of molecules of O_4 has also been suggested by Wulf (*Jour Amer Chem Soc*, **50**, 2596; 1928; *Proc Nat Acad Sci*, **14**, 609; 1928), on the ground of optical data, concerning the absorption spectra of liquid and gaseous oxygen. The identity of absorption spectra due to molecules of O_4 in the liquid and the gaseous states shows that the action of oxygen molecules does not produce any appreciable change in the energy levels of the molecule O_4. On account of this fact, we may suppose that the dissociation energy of O_4 cannot differ considerably in the liquid and gaseous states. For Sutherland's constant for oxygen, different authors give values varying from 127 to 138. These figures are very near to that obtained by Lewis for D. Further experiments will show whether it is a mere coincidence or not.

Experimental work on this problem is in progress in the laboratory of Prof N N Semenoff in this institute. In conclusion, we wish to extend our thanks to Prof J Frenkel for his kind advice.

The 'Common Third Level' in the Raman Effect

In recent communications to Nature, Langer and Dieke have pointed out that generally the shifts observed in the Raman spectra correspond not directly to the absorption frequencies of the scattering substance but to *differences between its absorption frequencies*, and that this is in accordance with the dispersion theory of Kramers, Heisenberg and Schrödinger. As a consequence of the quantum dispersion theory, the probability that we should observe a shift of Raman lines corresponding to the transition $E_i \to E_k$ is dependent on the probabilities of the transitions from $E_i \to E_n$ and from $E_k \to E_n$ where E_n is any third common level. The purpose of this note is to point out the significance of the common level from a physical point of view.

In the case of scattering of light by free electrons Pauli (further extended by Einstein and Ehrenfest) (*Zeits für Phys*, Band 18 and 19) showed that the probability of scattering of light of frequency ν', when the incident light has the frequency ν, is $\alpha\rho_\nu + \beta\rho_\nu\rho_{\nu'}$. From the classical point of view, scattering is really made up of two processes taking place simultaneously, namely, (1) absorption, (2) re-emission. Hence, even in cases when the frequencies of the incident and scattered light are different—that is, the scattering is not classical—we should expect, from the general ideas of correspondence between classical and quantum concepts, that the mechanism of the process should still be essentially the same as it will be in the limiting classical case. In all cases of scattering, two processes must always take place, (1) absorption and (2) emission. The probability of (1) from the point of view of Einstein is $B_{12}\rho_\nu$, and of (2) $A_{21} + B_{21}\rho_{\nu'}$, and hence the probability of scattering of ν' is $= \alpha\rho_\nu + \beta\rho_\nu\rho_{\nu'}$, where $\nu = E_2 - E_1$, $\nu' = E_2 - E_1$.

These considerations can now be applied to the Raman effect.

Let us consider scattering from a molecule possessing only two levels E_i and E_k. When light of frequency ν is incident and is then scattered, the two processes which take place are

(1) Absorption—the molecule passes from $E_i \to E_k$,
(2) Re-emission—the molecule passes from $E_k \to E_i$,

and thus, on the whole, the molecule neither takes nor gives anything to the incident quantum, and so the frequency of the scattered light remains ν. If a molecule has only two levels, it cannot give rise to combination (Raman) scattering.

If there be a third common level E_n, the molecule during the processes

(1) may pass from $E_i \to E_n$,
(2) may return from $E_n \to E_i$ or $E_n \to E_k$,

giving rise to the unmodified and the modified lines.

Combination scattering (Raman effect) is, therefore, entirely dependent upon the existence of a third level, and this view also enables us to calculate the intensity of the modified lines.

Kramers and Heisenberg in their original paper discussed the possibility of another allied effect which is theoretically as important as the Raman effect, but has not yet been observed. Generally ν_{ik} is much $<< \nu$, but if $\nu_{ik} > \nu$, as we should expect only in electronic transitions, then when the molecules are illuminated by light of frequency ν, it should excite in the scattered radiation light of frequency ν and $\nu_{ik} - \nu$. A molecule in the excited state k, when subjected to the field of frequency ν, is forced to emit radiation ν. To do this the molecule should revert from the state ν_k to the normal state ν_i, and the balance of energy $\nu_{ki} - \nu$ will appear as another quantum. It can be easily seen that the experimental verification of this prediction will be much more difficult than that of the Raman effect, as we must have a sufficiently large number of molecules in the much largely energy richer state ν_k.

We may be permitted to mention that the possibility of such an effect was discussed in the local Science Colloquium on Nov 22, 1929, but we did not publish our views in the hope of gaining some experimental verification. The same view has been expressed by Göppert in a recent note in *Die Naturwissenschaft* (Nov 29, 1929), but no experimental verification has yet been obtained.

The Fallacious Determination of the Specific Heats of Gases by the Explosion Method

The recent gales suggest how fortunate a thing it is that the rate of motion of gas in an equilibration of pressure is not that of sound, which is of the order of 740 miles per hour. The phrase, common among students of gas explosion phenomena, that 'pressure equilibrium is attained at the speed of sound' has, indeed, on analysis, no meaning whatever; the rate at which gas moves over a point is a function of the pressure gradient at that point.

Since the 'eighties, many attempts have been made to determine the specific heats (C_v) of gases by measuring the maximum pressure reached in an explosion of such a mixture that the gas in question is one of the residual gases Such determinations are fallacious, for when the experimenter has taken the elementary precaution (foreshadowed by Mallard and Le Chatelier) of using a sphere, with central ignition, so that at the moment of maximum pressure all the gas has suffered the passage of flame—a consideration which also dictates the use of a mixture through which flame passes so quickly that buoyancy may be neglected—there is still the difficulty, stated by Sir Dugald Clerk, that the combustion is not then complete

This incompleteness is not mainly a surface phenomenon, the effect of which would be small and eliminated by the use of different vessels Ellis and Wheeler have shown that the combustion is most nearly complete in the gas which suffers the passage of flame in the later stages of the inflammation, when the pressure is high, and that the combustion of the gas ignited earlier continues for some time after the moment of maximum pressure—it may be for a period many times as long as that taken by the flame to spread through the vessel

This result may be shown independently, as follows Inflammation of the mixture is achieved gradually in successive portions by a continuous ignition, shell by shell, each shell at an initial pressure a little higher than that of its predecessor, and each shell over a greater surface than its predecessor's As each successive portion of the gas mixture is thus inflamed, it expands, thus making its own contribution to the increasing pressure, which is entirely derived from this continuous succession of local expansions On the face of it, one should be very chary of assuming either that the work it lends the system, by its temporary expansion, is necessarily fully repaid again by subsequent compression to initial volume before the moment of maximum pressure, when the last shell of gas is inflamed, or that inflammation when the pressure is low follows the same chemical regime and reaches the same chemical goal as when it is high

To recognise a continuous succession of local expansions is to recognise in the flame surface a watershed source of continuous pressure generation a pressure gradient, accompanied by an equilibrating surge, extends inwards towards the centre, and a second pressure gradient, accompanied by an equilibrating surge, extends outwards to the wall We are concerned in this letter chiefly with the state of affairs at the moment of maximum pressure, when the last shell of gas becomes flame It is evident that the inward gradient and the inward equilibrating surge must now extend from the wall to the centre The speed of this surge, which is the immediate agency by which the inner gases are recompressed toward their initial volume, has, from its inception, been increasingly affected by the chemical action which it has continuously and increasingly induced in the gases suffering this recompression, its speed now begins to be affected also by the contraction of gases in its rear as they lose heat by conduction to the wall of the vessel This surge must spend itself before the output of energy from the inner gases can be regarded as having ceased

As corollaries, it may be noted that the inmost portions of the gas are never subjected to a pressure quite so high as that reached by the outermost and registered at the moment of maximum pressure by the manometer at the wall, also that these portions are never recompressed quite to their initial volume if they finally reach it, it is by cooling

When the vessel is not spherical, the inward surge may be faster or slower according to the shape of the vessel and the incidence of the cooling losses An interesting snapshot photograph of such a surge may be consulted in *Fuel*, 410 (1928)

Summarising, the constitution of the gas in an explosion at the moment of maximum pressure is not known, but it is impossible that it is homogeneous, or that the combustion ceases before sensible cooling has supervened

OLIVER C DE C ELLIS

Reversibility of Evolution

I HAVE read with deep interest the report of the lecture by my old friend, Prof H Fairfield Osborn, on "Tertiary Man", published in NATURE of Jan 11 In this lecture Prof Osborn stresses very strongly Dollo's principle of the irreversibility of evolution, that is, the doctrine that once a structure has been lost by an animal through disuse, even if changed circumstances should again make it useful it cannot be revived

Whilst accepting this principle as applying to the majority of cases, there are certain exceptions to it which put us on our guard against asserting it unconditionally One of these—particularly clear—I should like to refer to here The original dermal armature of the craniate vertebrate appears to have consisted of small teeth embedded in the skin such as are retained to day in the placoid scales of sharks and rays As time went on the bases of groups of these teeth became bound together by an ossification of the connective tissue beneath them, and so the bony scale, still found in the archaic 'ganoid' fish, *Polypterus* and *Lepidosteus*, was produced On the surface of these scales minute microscopic teeth can be detected Later, as the earlier Mesozoic fish developed into the first true Teleostei of the Cretaceous period, not only these teeth but also the bony layer disappeared, and the scale became a mere horny film as it is in the majority of fish to day

Some time in the earlier Eocene these herring like early Teleostei threw off a fresh water branch, the Siluroids or catfish The typical catfish has lost the scales altogether, but some South American forms which inhabit torrential streams, possibly owing to the habit of pressing their bodies closely against the bottom, have redeveloped bony plates in the skin, and, in some genera, on the surface of these plates *small dermal teeth in all respects identical in structure with the placoid scales of sharks*

I remember well when this extraordinary fact was demonstrated to me by my friend and fellow student, Pollard, of Christ Church, Oxford, when we sat side by side in Naples in 1892 It was fully described by Hertwig and was well known at the time

I respectfully ask Prof Osborn to estimate how many million years intervened between the time that the ancestors of Siluroids lost their teeth and the time when their descendants redeveloped them

We must admit, therefore, that even after an organ has ceased to appear in the normal development of a creature, the power to produce it still remains for an indefinite but varying time embedded in the organisation of the animal and can be revived if the appropriate circumstances recur

This power may be aptly compared to habitudinal memory, and its calling into action resembles the revival of a half forgotten habit

Tertiary Man

In Prof Fairfield Osborn's address on "The Discovery of Tertiary Man" (Nature, Jan 11, p 55), it is stated, in regard to the discoveries I have made in East Anglia, that Prof Breuil "shifts the entire pre Chellean and Chellean flint industries from mid-Quaternary down into the base of Quaternary time, namely, into the first Interglacial or Mindel-Riss stage" The first inter glacial is, however, that of the *Gunz Mindel*—according to the Penckian scheme—and it is to this phase—represented in East Anglia by the Cromer Forest Bed—that Breuil now relegates the Chellean industry Prof Osborn had no doubt in mind Breuil's recently published list of his scientific papers when writing the address referred to, as in this list the impression is given, no doubt unintentionally, that the author was the first to refer the Chellean implements to the first inter glacial epoch This impression is, however, incorrect, as no less than ten years ago, in 1920, I published a note in the *Geological Magazine* (vol 57, No 671, May 1920, pp 221 224), in which, with much detail, I set forth my views on the relationship of palæolithic man to the glacial period, and stated (p 223) that "The Chellean implements may therefore be of *Gunz Mindel* inter glacial age" When I made this announcement, to which I have adhered with ever increasing conviction, few, if any, archæologists agreed with my opinion, and it was only after several visits of Prof Breuil to East Anglia that he was convinced of its truth

Entomophagous Parasites and Phagocytes

In his interesting letter in Nature of Jan 4 on the parasites of the pine shoot moth, *Evetria buoliana* Schiff, Mr C C Brooks gives some figures which seem to indicate a correlation between the percentage of parasitism and the size of the emerging moths, and advances the view that the diminution in size, which he has observed in moths from areas in which the parasitism is high, is due to the fact that some of the parasitised larvæ have recovered from the parasitic attack, so that the adult is able to emerge, although it shows the effect of the feeding of the parasites in its unusually small size

It is not uncommon to find in caterpillars or pupæ the remains of dead parasites, but so far as I have observed, this is rather rare in cases where the parasitic larvæ have reached a stage so advanced as those mentioned by Mr Brooks His suggestion is, therefore, a highly interesting one, and it is to be hoped that he will be able to verify it by dissections

My object in making these comments is not, however, to discuss the hypothesis put forward by Mr Brooks, I simply wish to make a few remarks in regard to the view he has expressed concerning the process of recovery from parasitism, and more especially the part played by phagocytes in cases of this kind

The evidence in favour of the views advanced by Mr Brooks is, on the whole, very unsatisfactory What the data actually indicate is that the part played by phagocytes in relation to insect parasites is of very little importance Metchnikoff, the founder of the phagocytic theory of immunity, long ago pointed out in his "Lectures on the Pathology of Inflammation", that the phagocytic reaction of Arthropods is, in general, very feeble

In his excellent work on the biology of the parasitic Diptera, J Pantel (*La Cellule*, 26, 1er fasc, 1910), whose conclusions were based on the study of a large number of species, states that as a general rule the free and healthy larvæ of entomophagous insects are not attacked by phagocytes

My own conclusions, based upon the dissection of thousands of individuals of insects belonging to practically all orders, and infested by entomophagous parasites of many groups, agree perfectly with those of Pantel Healthy parasites, no matter in what stage of the host they are found, are practically never surrounded by phagocytes, provided they lie free within the body cavity of the host There is no particular reason for believing that the parasite larvæ repel the phagocytes In sections of parasitised hosts the blood cells seem to be just as numerous in the vicinity of the parasite larvæ as they are in other parts of the body They are simply indifferent to the parasites, as they are to the organs of the host itself On the other hand, if a parasite has an anatomical relation with the host, of such nature that destruction of tissue is produced, a considerable accumulation of phagocytes may occur around the point of the lesion The extent to which phagocytes accumulate is variable and appears to depend in part upon the specific nature of the host, and in part upon its general condition On the other hand, an accumulation of phagocytes does not appear to exert any effect whatever on the healthy parasites

A brief summary of the results obtained by me up to that time was published in 1915 (*Bull Soc Zoologique de France*, 40, pp 63 68) A detailed account is now in course of preparation

Scattering of α-Particles by Light Atoms

In a recent discussion at the Royal Society (Nature, vol 123, p 246), Sir Ernest Rutherford pointed out the great importance of the experiments on the scattering of α particles by light atoms like those of magnesium, aluminium, helium, and hydrogen which are being carried out at the Cavendish Laboratory by himself and his co workers Bieler, Chadwick, and others The results of these experiments show very wide variation from the classical expression obtained on the assumption of an inverse square law, and led Rutherford and Bieler to the view that the repulsive force between positively charged particles changes into an attractive one when the distance of approach is less than 3×10^{-13} cm Many attempts have been made to get an exact expression for this force Bieler thought the force to be given by the law $F = \frac{Ze^2}{r} - \frac{\mu}{r^4}$, while Debye and Hardemeier took the additive term to be inversely proportional to the fifth power of the distance

While the exact form of the law will probably take some time to discover and will probably be given by some developments in the generalised theory of relativity, it is profitable to see how far the assumptions of these additional forces can be justified from the point of view of wave mechanics Born has given a general way of treating collision problems on wave mechanics, and Wentzel, Sommerfeld, and Mitchell have deduced, by the use of Born's method, Rutherford's classical expression for the scattering of α particles I have tried to explain abnormal scattering of α-particles by light atoms from wave mechanics by using the law $F = \frac{Ze^2}{r^2} - \frac{\mu}{r^n}$ It appears that the equations can be solved by the polynomial method only when $n = 3$ Using this value of n, I have deduced an expression for scattering which is in very good agreement with the results obtained in the Cavendish laboratory

The assumption of the same law in Schrödinger's

equation enables us to calculate the 'Eigenwerte' of α-particles in the nucleus Discrete positive as well as negative 'Eigenwerte' are obtained, according to initial conditions assumed The positive 'Eigenwerte' are very interesting, because with certain further assumption they are capable of explaining the γ rays of the six radioactive elements which have been so far accurately measured The numerical agreement is very remarkable

The complete papers will be published in the *Philosophical Magazine*

Nitrifying Bacteria

During the course of investigations on nitrification in soil and in a sugar beet effluent filter bed, several different bacterial strains have been isolated capable of oxidising various ammonium salts to nitrite, as shown by the Griess Ilosva method This is interesting because it has usually been assumed that nitrite formation was brought about by the varieties of bacteria known as *Nitrosomonas* and *Nitrosococcus* first isolated by Winogradsky in 1891 There are, however, scattered references in the literature to other organisms capable of producing nitrite from ammonia, but unfortunately the diagnostic characters given are insufficient for sure identification Among the well known characteristics of Winogradsky's organisms are the following inability to grow on nutrient agar or gelatine, inhibiting effect of organic compounds such as sugar, optimum growth at pH of 7 7 – 7 9 In contrast to these the organisms isolated in this laboratory grow well and rapidly on both nutrient agar and gelatine (in the case of the soil forms Winogradsky's medium is unsuitable), the presence of 0 1 per cent sucrose in no way inhibits growth, and in the soil forms definitely stimulates nitrite production Nitrite formation takes place at a wide range of pH values varying from 4 5 to 7 9

Further, morphologically, the varieties of *Nitrosomonas* and *Nitrosococcus* on the whole do not resemble the soil and effluent forms isolated here

This new group of organisms has up to the present been shown to produce nitrite when grown in a culture solution of the following percentage composition 0 06 sodium chloride, 0 002 calcium chloride, 0 0005 magnesium sulphate, 0 03 potassium acid phosphate, 0·1 sucrose, the only sources of nitrogen being one of the following ammonium salts, sulphate, phosphate, carbonate, chloride, lactate, or acetate Some of the strains produce nitrite from all the ammonium salts tested, while others will only produce it from certain of them On the whole, the organisms isolated from the effluent produce nitrite more freely from ammonium lactate and the soil forms from ammonium phosphate

A full description of these bacteria, together with their physiological reactions, is in the course of preparation

The Life-Cycle of *Bac saccharobutyricus* v Klecki

In 1927, Cunningham and Jenkins (*Jour Agric Sci*, Vol 17, pp 109 117) showed that under certain conditions the motile butyric acid bacillus is capable of producing aerobic micrococci Studies of this organism continued during the intervening period of three years have demonstrated that it passes through a life cycle in which at least seven distinct cell types can be distinguished—forms similar to the (1) coccoid, (2) short rod, (3) slender rod, (4) large rod, (5) dwarfed growth, (6) fungoid, and (7) large cell types of Löhnis and Smith Of these, representatives of types 1 to 4 have been stabilised and the majority have been identified with previously described 'species'

The cocci consist of white, orange, and red forms corresponding to *M candicans* Flugge, *M aurantiacus* Cohn, and *M roseus* (Bumm) L et N The short rods are represented by unidentified white and red types The more important of the slender rods are *B putrificus* Bienstock, *B sporogenes*, Metchnikoff, *B putrificus* Reddish and Rettger, *B circulans* Jordan, *Pectinobacter amylophilum* Makrinov, and *B Globigii* Migula, while the large rods are represented by *B Ellenbachensis* Stutzer and *B sphæricus* A M et Neide

Formation and germination of endospores, exospores and microcysts have been observed as well as formation of gonidangia, gonidia, and regenerative bodies Observations have also been made on the formation of, and regeneration from, the symplasm, and on conjunction with formation of regenerative bodies at the points of contact of the cells When cultures of the slender rod type produce terminal regenerative bodies they have been found to be capable of decomposing cellulose under anaerobic conditions A detailed account of the results of the investigation will be published elsewhere

Regeneration of the Spines in Sea-Urchins

In Nature of Nov 16, p 760, Mr H C Chadwick records a case of regeneration of the spines in *Echinus esculentus* While working at the Marine Laboratory, Plymouth, last summer, I noticed a number of specimens of *Psammechinus miliaris* behaving in a similar way The individuals belonged to a small, deep water race obtained from about 15 fathoms near the Eddystone On July 25 about thirty specimens were placed in a bowl under circulation and kept in darkness A similar number were exposed to direct sunlight The former lot remained healthy and underwent no change About half of the lot kept in the light threw off all their spines except those on the oral surface, which were unaffected A week afterwards a fresh crop of minute spines began to appear These grew so rapidly that in two months the majority of these individuals could scarcely be distinguished from those which had not thrown off their spines

It may be noted that Dr Mortensen states in his "Handbook of the Echinoderms of the British Isles" (1927, pp 262 263) that in sea urchins "The power of regeneration is great, spines and the other external organs are easily regenerated Autotomy is not known to occur in the Echinoids"

Ruthenium a Superconductor

In some experiments recently made in collaboration with J F Allen and J O Wilhelm, we found ruthenium became superconducting at 2 04° K The metal was supposedly of high purity, but retained its high resistance down to nearly 4° K

J C McLennan.

The Great Telescopes of the Future[1]

FOR some ten years past visitors to the Observatory of Paris have found Dr Ritchey installed on the top floor, working out his optical ideas. These ideas are the fruit of his long experience in the use and construction of telescopes, first at Yerkes and later at Mount Wilson. They are thus very mature, and unless we are to discard experience altogether, they deserve the most careful consideration.

The publication before us has been distributed by the great glass making firm of St Gobain. M Delloye, the manager, to whom Dr Ritchey pays many grateful acknowledgments, states that it arose from the wide interest excited by a presentation in Paris, by the Company, of Dr Ritchey's celestial photographs. Accordingly, to make the presentation permanent, the company has issued half-tone reproductions of nineteen of the finest photographs, together with several others illustrating Dr Ritchey's experience and projects. Most of the pictures are included in the excellent series of astronomical photographs which are available through the Royal Astronomical Society, and one gets the impression that they are familiar by their incorporation in various popular books. A careful scrutiny, however, shows that the present publication leaves far behind the best that has been produced before, and in that connexion it is germane to recall that *all* the best photographs of stellar and nebular fields were made by Ritchey, and the most sensational of them were made by telescopes the chief parts of which, both optical and mechanical, he had made, and in many cases had devised also. On revision of that sentence one may add Barnard's name, but no other. This should not be forgotten in considering the outlook for the future.

The text of this brochure has been written in English, and translated into French, somewhat carelessly. Both versions appear side by side. In no case is the French an improvement upon the author's careful wording. In one case the French text achieves the exact opposite of the English, as when "Nous avancerous ainsi lentement, mais sûrement" does duty for "We shall thus advance by *long, sure* steps". What is of interest, in addition to these epoch making photographs, is an outline of Ritchey's view of the right construction for the great telescopes of the future. Those who wish for a fuller account of the same will find it in the *Transactions of the Optical Society*, **29**, p 197 (1928)—the Thomas Young Oration—where details, numbers, and references, here lacking, are given.

It is evident from this publication that Ritchey is still ardent and unwearied in the pursuit of more, and still more, perfect and powerful optical means. That may seem an obvious thing to say. But improvements of means demand an ever stricter discipline in their use, and there is a good deal to be advanced for getting full service out of the instruments we possess. It is possible to spend so much time in preparation that nothing is left for achievement. But let that be the consolation of those who must be content with something less than the best. It is evident that if we are to penetrate further into space—and the remote, small objects are at least as significant as those we happen to be near—we must have greater power. Now few look for a greater refractor than about 40 inches. Even the 100 inch reflector is not likely to be surpassed without change of plan. But as readers of NATURE know from an article in the issue of Dec 21, 1929, the California Institute of Technology has been furnished with the funds for a reflector of 200 inches, and the plans are already energetically advanced, by Dr G E Hale, assisted by investigators of every type. In the conduct of these investigations no door has been closed in advance, and any location and any type of telescope may be adopted. But so far as they go, they seem to point to a repetition of the 100 inch as to mounting, and as to the mirror, a solid disc of fused silica, faced with fused quartz. The total weight of the moving parts is estimated at 500 tons. To intensify the light gathering the focal ratio is to be unusually short, 3 3, and is to be shortened still further by an interposed lens which is also to correct the field for coma.

Everything depends upon a right choice, but it is scarcely the place of those outside the scheme to follow the decisions that must be made with anything except hearty good wishes for their success.

The design of a super telescope to which Dr Ritchey has been led, and which he has gradually developed, but varied very little, in a lifetime of study, is quite different, and in many ways it is bolder in its novelties. First of all he would not have a solid mirror, which for the 200 inch size must weigh 30 tons. He could build it up of a back- and a face plate, separated by a honeycomb structure, also built of thin plates of the same composition. Weight could be reduced to one quarter, support could be made by flotation, or at the centre of gravity, air could be circulated throughout. A reduction in the weight of the mirror permits a proportionate reduction elsewhere. Intensification of light gathering and correction for coma would be produced by 'figuring' from a Cassegrain model, on a plan devised by Prof Chrétién and himself. The telescope building would be in the form of a tower, at the top of which would be a dome containing two flat mirrors of which one only rotated in the ideally simple cœlostat manner, and sent a vertical beam through the centre of the tower to the great mirror which lay fixed in a horizontal position. This construction permits immediate change of the secondary mirrors, thus multiplying the uses of the telescope. Not unimportant, the observer would also be in an easy position. There are many other details of technical interest, but they must be passed over here.

It is again scarcely useful to express or to form an opinion upon these proposals. What is impracticable to one pair of hands, may be perfectly successful in another. Most seems to depend upon the

[1] L'Évolution de l astrophotographie et les grands télescopes de l avenir (The Development of Astro photography and the Great Telescopes of the Future). Par G W Ritchey. Publié sous les auspices de la Société Astronomique de France. Pp 36+34 planches. (Paris.)

success of the built up mirror Cemented glass is usually reckoned a tricky construction, with a horrible aptitude for flying and tearing flakes off the face it is cemented to As against this, Dr Ritchey in 1911 and 1912 made two flats in this way, 20 inches in diameter, and they have since behaved beyond reproach He figures in these publications the honeycomb part of a 60-inch mirror, and also a more advanced stage, but it does not appear to have ever been completed If it is a question of funds, I submit that it would be well worth the while of those interested in the major problem, to see that that experiment, which has been carried so far, is tried out and not left inconclusive R A S

Denudation in the Punjab Hills

THE denudation of mountain slopes, as a result of the ignorant clearance of forest under the combined activities of the lumberman, fire, and excessive grazing, and the resultant damage is not a new problem and has been previously referred to in NATURE For centuries the Alps have furnished examples of the difficulties which governments have to contend with in combating the ignorance of the local population on the subject of the actual causes from which the trouble arises Throughout the Mediterranean, large areas of bare hills form an object lesson of the same kind, whilst America provides the most recent examples of the inevitable results following wholesale destruction of the vegetation in hill and mountain areas through excessive logging, often followed by extensive fires, and over grazing A recent paper on "Denudation of the Punjab Hills" (*Ind For Records, Sylv Series*, vol 14, pt 2, 1929), by Mr B O Coventry, traces the history of denudation and its results in the province Mr Coventry is a conservator of forests and has been in the province since 1895 His treatment of this important matter and the conclusions he has arrived at merit careful attention

The monograph commences with a consideration of the forest vegetation and evidence of denudation The main topographical tracts are distinguished as (1) The Himalayan tract, (2) The Sub Himalayan tract, comprising the lower hills up to about 3000 ft and including the Salt Range on the west and the Siwaliks on the east, two outlying ranges of hills rising from the plains to about 3000 ft, (3) The Plains

The climate in these regions varies considerably, the rainfall being about 30 in per annum near the foot of the hills to 5 in or less in the south of the Plains Mr Coventry, in considering the denudation problem, divides the climatic or forest zones as follows (1) *Plains*—Tropical zone (below 1000 ft), zone of *Prosopis spicigera* (2) *Sub-Himalaya*—Sub Tropical Zone (1000 ft to 3500 ft), zone of *Acacia modesta* (forests in east differ from those in west) (3) *Himalaya*—(a) Sub-Temperate Zone (3500 ft to 5500 ft), zone of *Pinus longifolia*, (b) Lower Temperate Zone (5500 ft to 7500 ft), zone of *Pinus excelsa*, Upper Temperate Zone (7500 ft to 9500 ft), zone of *Abies Pindrow*, Sub-Alpine Zone (9500 ft to 12,000 ft), zone of *Betula utilis*, Alpine Zone (above 12,000 ft), no tree growth

It will be understood, as is invariably the case in mountainous regions, that aspect, exposure, and latitude modify the appearance of a species in a locality, and there is no clearly marked line of demarcation between two adjacent climatic zones though these are separated by what may be regarded as a 'neutral zone' where species of the two zones flourish equally well Moreover, each of the above forest zones is not occupied by one type of forest alone, but different kinds of forest occur in the same zone, and the factors determining the distribution of the types are edaphic or soil factors The species which will regenerate on dry soils are termed 'xerophytes', and those which require moist soils 'mesophytes' These terms become important when it is considered that whereas a seedling may find the requisite soil conditions to enable it to become a well established tree, its root system then going deep down in the soil, subsequent denudation may remove all the surface soil, thus preventing further seedlings developing on the area Owing to this fact, as the author points out, and to the great age to which some species live, "it is not uncommon to find a forest of a particular species growing on a soil" or even on bare rock "which is quite different from the kind of soil it requires for its natural regeneration or upon which its distribution is dependent" A change from a xerophytes type of vegetation to a mesophytes type in the series is regarded as a case of 'progression', whilst the contrary is looked upon as a case of 'retrogression' One part of Mr Coventry's observations has been devoted to a study of the 'retrogressive' changes in the vegetation of the Punjab Hills After discussing the forest vegetation in the different forest zones (for which the reader is referred to the monograph) the retrogressive changes in the different zones are summarised as follows

The forests in each zone are generally undergoing retrogression In the Sub Tropical zone the climax formations of olive (*Olea cuspidata*) forests and other mesophytic types are changing to brushwood forests of *sanatha* (*Dodonaea viscosa*) In the Sub Temperate zone the mesophytic and climax formations of oak are changing to *chir* pine (*P longifolia*), and the *chir* pine forests are generally deteriorating in quality In the Temperate zone climax formations of oak or other broad leaved species are changing to blue pine (*P excelsa*) In other words there is a general tendency for the climax and mesophytic types to change to more xerophytic types indicating a general change from moist to drier soil conditions Although these conclusions have been arrived at from observations with regard to the vegetation chiefly on the Murree and Kahuta hills, they apply

more or less equally to the vegetation on the hills throughout the Punjab, including the Indian States of Kashmir, Chamba, Poonch, etc

Evidence of denudation is then considered, and everyone having acquaintance with the Province will appreciate the truth of the following description

A considerable proportion of the hills of the Punjab, exclusive of areas under cultivation, are bare of forest vegetation, especially in the lower zones, but it is evident from a study of the forest vegetation of the neighbouring wooded hills, and even to the most casual observor, that these bare hills were previously densely wooded everywhere within the limits of tree growth and at no very remote date There is evidence in some localities of hills having become denuded of their forest vegetation within comparatively recent years, and the older inhabitants of many of the villages can give instances where hills have become more or less denuded within their lifetimes Considerable areas of village forest lands which were known to be well wooded at the time when the Forest Settlements were drawn up about forty to fifty years ago, have since been more or less completely denuded of their vegetation, especially in the lower hills Some of the villages now experience considerable difficulty in obtaining sufficient timber and firewood or fodder, whereas formerly they had ample supplies available There is evidence in old historical records of hills which are now in a denuded condition being previously densely wooded For instance, in the Gazetteer of the Kangra District there is an interesting account taken from old records of the conquest of Mau and Nurpur under Shah Jehan about 300 years ago, in which reference is made to the 'impenetrability of the jungles' at that time, but these jungles are no longer existent Again some of the old Atlas sheets prepared from surveys made 60 70 years ago show tracts of low hills as densely wooded, which are now in a denuded condition

Although there is ample evidence of great denudation having taken place in the past, the retrogressive changes accompanied by erosion of the surface soil which have been shown above to be taking place in the existing forests is evidence that denudation is still actively in progress at the present day, and it requires little imagination to foresee that if this steady process of denudation continues unchecked the hills of the Punjab must sooner or later become more or less completely denuded of soil and vegetation and reduced to a desiccated condition

As to the causes, Mr Coventry dismisses the theory that there has been any change of climate responsible for the desiccation, remarking that there are living trees in existence of olive, oak, and deodar which cannot be less than a thousand years in age, and these species still regenerate and grow vigorously in the same localities provided the conditions of soil are suitable In common with a number of other authorities, he allocates the blame for the present state of the hills upon man, (and not climate), to whom the retrogressive changes in the vegetation are due, the changes being traceable to changes in the soil following erosion

If, however, the erosion of the surface soil is simply to be regarded as the normal result of disintegration and gravity and has always been in progress to the extent to which it is taking place at the present day, it becomes impossible to explain how the hills ever became clothed with forest vegetation, and especially with the climax formations on deep deposits of humus soil This can only have taken place when there was a condition of more or less equilibrium, that is to say when soil was accumulating as rapidly as, or more rapidly than, it was being eroded away, and it seems evident, therefore, that some factor has come into play which has upset this previous condition of equilibrium, resulting in erosion of the surface soil, which is gradually denuding the hills of soil and vegetation All the evidence which is forthcoming shows very conclusively that this factor is man, by means of fires and grazing of his cattle

Outside the broad leaved type, when not opened out, the only type of forests which are resistant to fire are the Chir pine forests These have been burnt periodically from remote times The persistence of the tree is due to its thick bark But each time the forests are fired a certain amount of soil erosion follows, and eventually the forest degenerates into scattered stunted trees standing on more or less bare rock, of which there is an excellent illustration in the monograph Next to fire comes grazing of the large flocks which the hill people keep, exceedingly poorly bred and of little value The trouble during the past fifty years has been due to the almost unlimited recognition by the old Settlement officers of the peoples' rights to graze the flocks over large areas of the hills With the impoverishment of the forests and increasing denudation, grass and browsing materials greatly decreased and the people took to lopping the trees In the Report of the recent Royal Commission on Agriculture in India (1928) it was remarked that no complaints as to serious damage being done by lopping of trees were received There are, however, plenty of instances in the North West Himalaya, the practice is a most serious factor in the work of denudation

It is unnecessary to follow the author into his treatment of the effects of denudation—floods, water supplies, and irrigation, and so forth As regards remedial measures he prescribes the introduction of an organised pasture management He does not appear to be acquainted with the methods found in France, where areas of pasture are managed in conjunction with rougher grazing and timber forest (from which animals are excluded) The whole area may be communal or village owned—but is managed under the supervision of the Forest Department This system of management is on the lines Mr Coventry advocates, but in France it is established

In the Punjab the Government is faced with the difficult work of afforesting the denuded areas This will demand high skill and sufficient funds But that the matter is urgent Mr Coventry's monograph well displays Others have stressed the same warning The fate and future of the great irrigation schemes in the Punjab plains are directly dependent upon the preservation of the water supplies in the hills and the prevention of further denudation and the arrest of what is taking place Government has already had warnings by means of bad floods in the past

Last year flooding and wholesale damage were on a terrible scale, and it may be hoped that the appearance of Mr Coventry's brochure may pave the way to a better understanding of this serious problem

The monograph may also be commended to the Colonial Office and its officials For there are many other parts of the British Empire where the same conditions as Mr Coventry describes in the Punjab Hills are being produced and by the same agencies It forms one of the large and pressing problems of the day in such regions

Obituary.

Dr Sebastian Z de Ferranti, F R S

SEBASTIAN ZIANI DE FERRANTI was born in Liverpool on April 9, 1864, and was educated at Hampstead School, St Augustine's College, Ramsgate, and at University College, London Even from his earliest days he showed a great bent towards engineering invention, and before he left school he began to build a dynamo When he was only seventeen years of age the first Ferranti machine with its coreless disc armature was installed in the arches under Cannon Street Station In the year 1882 he and Mr Francis Ince went to Glasgow to interview Sir William Thomson (Lord Kelvin) to try to arrange a working agreement with him, as it was found that one of Thomson's patents partly anticipated Ferranti's invention An agreement was arrived at, but it placed rather too heavy a burden on their manufacture In 1883 the firm of S Z de Ferranti and Co, the forerunner of the large works at Hollinwood, Manchester, was established at Charterhouse Square I remember going over this factory so long ago as 1890 and being greatly impressed by seeing hundreds of Ferranti meters all connected in series being tested

In 1883 the late Lord Crawford and Sir Coutts Lindsay decided to adopt electric lighting at the Grosvenor Gallery in Bond Street They installed a small plant, but the urgent requests of neighbours led them to enlarge it, and Ferranti was put in charge He planned 2500 volt overhead conductors and underground mains, and supplied an area extending from Regent's Park to Charing Cross and from Lincoln's Inn Fields to Albert Gate This was a marvellous feat for that period, but Ferranti's magnetic personality attracted an enthusiastic band of assistants, to whom he used to attribute much of his success He was soon convinced, however, that Bond Street was not a suitable site for a power station He saw that in order to supply electricity economically it was necessary to build a large generating station in a place to which coal could be conveyed cheaply, where rents were low, and where abundant water could be had for the boilers and condensers He visualised that to light London it would be necessary to obtain a site in the suburbs near the river and to transmit electricity to substations at the high pressure of 10,000 volts The site he selected was at Deptford, some eight miles from the centre of the load, and there he built a great power station, having machinery of more than 40,000 horse power and generating at 2300 volts The pressure was then raised to 10,000 volts and transmitted to the substations The scheme was taken up enthusiastically by Francis Ince, Lord Crawford, Lord Wantage, and others, and the London Electric Supply Corporation, Ltd, was founded

With practically no previous experience to guide him, as this was the first high tension station in the world, Ferranti designed by himself generators, transformers, mains, and all the necessary complicated switchgear Serious difficulties were soon encountered, amongst others the resonance phenomenon called the Ferranti effect At this period, when even his strongest supporters began to waver, Ferranti pushed resolutely forward, overcoming difficulty after difficulty, and undeterred by breakdowns until success crowned his efforts He frequently consulted Sir William Thomson professionally, and the latter found some of his problems of absorbing interest In particular he computed the effect produced by the rapidly alternating current in increasing the resistance of the Deptford-Trafalgar Square mains

In 1892, Ferranti resigned his post of engineer to the London Electric Supply Corporation, and devoted himself exclusively to the manufacture of electrical apparatus His works were finally established at Hollinwood, near Manchester They supply every kind of apparatus for electric lighting, and their transformers, meters, and radio apparatus are very widely used In particular Ferranti designed and installed the million volt transformer which is now in use at the National Physical Laboratory, Teddington

In 1910, Ferranti gave a remarkable presidential address to the Institution of Electrical Engineers, in which he prophesied the trend of future electrical development In the electrical age to which he looked forward all the world's drudgery would be done by automatic machines—'robots' driven electrically and controlled by human minds The enormous saving in labour and waste would be a priceless boon to humanity Assuming that everything were done as he suggested, he calculated that the average cost of an electric unit would be reduced to ⅛th of a penny He assumed that the nitrogen in the fuel would be recovered in the form of ammonium sulphate, which could be used for the intensive cultivation of home grown food Coal could be conserved, and as there would be less smoke there would be more sunshine It was a remarkable address delivered in a most pleasing and attractive way, as if it had been composed with little or no labour He told me, however, that he had spent laborious months composing it and checking the necessary calculations

Ferranti married the second daughter of Mr Francis Ince, a solicitor who gave a great impetus to the electrical industry in its early days One of Ferranti's sons, Basil, was killed in the War, after distinguishing himself as a major and gaining the military cross, another son, Vincent, is a director of Ferranti's Ferranti's home at The Hall, Baslow, Derbyshire, was fitted up with every electrical convenience, including even artificial sunshine His seaside house in Wales was also 'all electric'

He was a great motorist, and for his summer holiday he often went for a motoring tour abroad In the winter he and some of his family went to Switzerland for the winter sports On Dec 19 last he attended the meeting of the Institution of Electrical Engineers, at which Mr Haldane read a paper on a heat pump which reversed the Carnot cycle of operations Ferranti was enthusiastic over it, and reminded me that Prof Perry as well as Kelvin had advocated reversing the Carnot cycle He was just starting for his winter holiday, and was looking forward to skating and to seeing his children and grandchildren taking part in more active sports His death at Zurich on Jan 13, following an operation, came as a great shock to his many friends all over the world

Ferranti, through his father in law Mr Ince, was closely connected with Faraday House Electrical Engineering College At the old students' dinner on Oct 25, in proposing the toast of the College, he encouraged the students by reminding them of his own strenuous struggle during the days of his youth He missed in his student days, by a hairbreadth, the invention of the tungsten filament lamp and the induction motor He attributed these failures to lack of technical knowledge, and urged the students to use every endeavour to widen their knowledge One could never tell what scientific fact would give the key to an invention

Ferranti was a great inventor and engineer, one of the greatest the world has ever seen We need merely mention the mercury meter, the Ferranti alternator, the Ferranti rectifier, the Ferranti concentric cable, Ferranti switchgear, the Ferranti steam engine, the Ferranti steam valve, his system of earthing, his induction furnace, his high temperature improvements of the steam turbine, his systems of electric welding, and his high-speed spinning machinery for cotton mills There are many more Electricity supply as we know it to day was largely fashioned by him In England, in America, and practically all over the world, his name is a household word in engineering circles Yet he was a singularly modest and retiring man He never stood in the limelight or pushed himself forward for public recognition Foreigners after meeting him sometimes asked, wonderingly, "Was that the great Ferranti ?"

He was a fellow of the Royal Society, an honorary member and Faraday medallist of the Institution of Electrical Engineers, an honorary member of the American Institute of Electrical Engineers, and an honorary D Sc of the University of Manchester

A RUSSELL

PROF H L CALLENDAR, C B E, F R S

IT is with deepest regret that we record the death of Hugh Longbourne Callendar, professor of physics at the Imperial College of Science and Technology He was born in 1863, and died after a brief illness on Jan 21 last He leaves a widow and three sons

Callendar received his early education at Marlborough at a time when little encouragement was given to a brilliant scholar to take up any form of experimental science, and he passed through the school on the classical side In his first year at Trinity College, Cambridge, he received college prizes for classics and mathematics, obtained a first class in Part I of the Classical Tripos of 1884, and was bracketed sixteenth Wrangler in the Mathematical Tripos of 1885 Afterwards, however, his whole career was devoted to the experimental branches of physical science, in which he developed a degree of skill and a *flair* for accurate work that left him without a rival

Callendar's first work, on the platinum resistance thermometer, was communicated to the Royal Society in 1886, during which year he became a fellow of Trinity College, and his researches on temperature measurement were continued at the Cavendish Laboratory until 1893 After a brief interlude at the Royal Holloway College, Egham, he accepted appointment to a professorship of physics at McGill University, Montreal, remaining there for five years During this period he developed his method of continuous electrical calorimetry, the first application being the measurements by his assistant Barnes on the specific heat of water It was also at McGill that he first brought his knowledge to bear directly on the problems of engineering science, and in conjunction with Nicolson he made many valuable discoveries on the heat transmission and leakage losses from steam engine cylinders

In 1898, Callendar returned to England as Quain professor of physics at University College, London, and in 1900 he first put forward his characteristic equation for an imperfect gas which has been so useful and satisfactory in representing the properties of steam He accepted appointment as professor of physics at the Royal College of Science, now incorporated in the Imperial College of Science and Technology, in 1902, and still filled the chair at the time of his death His long occupancy of this post has been crowded with work representing not only the developments of his early researches but also brilliant and vital investigations on many new lines to which he turned his attention

Of the many services which Callendar has rendered to pure and applied science, it is difficult to say which should be placed first, but undoubtedly the most widespread utilisation of his researches lies in the applications of the platinum resistance thermometer In this instrument, Callendar not only gave to the research worker a method of the highest order of accuracy for the measurement of temperature, but also gave to the engineer and metallurgist a convenient and

practicable method of heat regulation in industrial operations To the perfection of the thermometer itself Callendar added the design of his automatic recorders and put the combination to many and varied uses His equation for an imperfect gas with his measurements of the properties of steam are similarly of universal importance It now seems so obvious that the values of the various properties of a vapour must be thermodynamically consistent with each other, yet of the many systems of steam tables in use throughout the world none possessed that vital attribute until Callendar showed the way He was spared to put the crowning touch to the edifice which he had erected, and last year saw the publication of his experimental values for steam up to and beyond the critical pressure He had long been dissatisfied with the usual presentation of conditions in the neighbourhood of the critical point, and his revelation of a differentiation in density and a latent heat beyond the temperature at which the meniscus vanishes came after a prolonged series of experiments which only he could have brought to a successful conclusion

Space does not permit of a detailed reference to Callendar's work on the gas thermometer, the radio balance, the re-determination of the specific heat of water, and the many other physical problems which he successfully attacked during his tenure in London Concurrently with these researches, he conducted a series of investigations on engineering problems connected with steam turbines and internal combustion engines, and in 1925 and 1926 he published papers on dopes and detonation, in conjunction with the staff of the Air Ministry Laboratory, which represented most valuable advances in the elucidation of that important but obscure phenomenon In all the major works which bear his name, he alone was responsible for every detail and every determination, and it may be that his most valuable contribution to science of the present day was the introduction of a new standard of accuracy for physical and engineering measurements The elimination of every possible source of error and the very highest degree of consistency alone would satisfy him

In his college lectures, Callendar was clear and concise, presenting his subject with logical sequence and perfect illustration He took few holidays, and was most happy when allowed to pursue his individual research steadily and without interruption, yet no interrupter was ever received with anything but perfect courtesy He was a good tennis player, and had won the Prince of Wales' Cup at Bisley for rifle-shooting He had been interested in motoring from its earliest days He was the inventor of a system of shorthand which is in fairly general use in some parts of the Colonies where older systems had not become firmly established prior to its advent He had no great liking for public lectures or for committee work, but accepted in his course such duties as they called He was for some years treasurer of the Physical Society of London, and was president in 1910–12 He was also president of Section A (Mathematical and Physical Science) of the British Association at the Dundee meeting in 1912 He was elected a fellow of the Royal Society in 1894, when only thirty years of age, and received the Rumford Medal in 1906 When the Physical Society of London established the Duddell Memorial Medal, to be awarded for the advancement of knowledge by the invention or design of scientific instruments, the name of the first recipient was a foregone conclusion and the medal was unanimously awarded to Callendar in 1924 He was a Hon LL D of McGill University, and at least one British university was desirous to bestow the same honour upon him, but he declined to leave his college duties during the examination period

It is pleasing to record that in the industrial world the work that Callendar did was valued, accepted, and used His steam tables were officially adopted by the turbine manufacturers of Great Britain through the British and Electrical Allied Manufacturers' Association, and used for turbine tests and contracts, and his later work on high-pressure steam was supported and financed by the manufacturers' research association He was awarded a Watt Medal by the Institution of Civil Engineers in 1898 for his work with Nicolson on the laws of condensation of steam, and received the Hawksley gold medal of the Institution of Mechanical Engineers in 1915 for his investigations into the flow of steam through nozzles and throttles, while in 1929 he was invited to deliver the Hawksley memorial lecture He was made a C B E in 1920 for his work for the Air Ministry and the Anti-Submarine Department of the Admiralty, but his most lasting memorial is the mark he has made on the science of accurate measurement H M

WE regret to announce the following deaths

Dr A J Bigney, professor of zoology in Evansville College, Indiana, and president in 1915 of the Indiana Academy of Science, on Nov 13, aged sixty five years

Prof Ralph H Curtiss, of Detroit Observatory and professor of astronomy at the University of Michigan, who was known for his work on stellar spectroscopy, on Dec 25, aged forty nine years

Dr Henry Wilson Hake, lecturer on chemistry and toxicology at Westminster Hospital Medical School, and consulting chemist, on Jan 18, aged seventy-two years

Prof F Neher, professor of organic chemistry since 1914 at Princeton University, who was known for work on the derivatives of halogenated ethers and esters, on Dec 11, aged sixty two years

Prof T Brailsford Robertson, professor of biochemistry and general physiology in the University of Adelaide since 1920 and officer in charge of investigations on the nutrition of animals for the Commonwealth Council for Scientific and Industrial Research, on Jan 25, aged forty five years

Rev F A Tondorf, director of the seismological observatory and professor of physics at Georgetown University, Washington, on Nov 29, aged fifty nine years

Sir Frank Warner, K B E, president in 1918–20 of the Textile Institute and a leading man in the silk industry of Great Britain, on Jan 23, aged sixty-seven years

News and Views

It was announced in the House of Commons on Jan 23, in reply to a question, that the Sub Committee of the Committee of Civil Research which is inquiring into the fishing industry has considered the problem of exploration for new fishing grounds, and, in view of the evidence put forward as to the need for systematic and well planned investigations, has presented an Interim Report to the Committee of Civil Research After considering this report, the Government has authorised the construction of a survey vessel at an estimated capital cost, including scientific equipment, of £80,000 The vessel is to be constructed and equipped by the Admiralty in a naval dockyard, and is to operate under the control and direction of the Hydrographer of the Navy The Government proposes to ask Parliament to provide annually a sum of £34,000 to cover running expenses in each of the five years next succeeding the completion of this vessel The Royal Research Ship *Discovery II*, a description of which was given in Nature on Nov 23, 1929, p 798, will be the pattern on which the new vessel will be constructed Specially designed for ice navigation, and with a bunker capacity sufficient to enable her to steam 7800 miles at full speed and more than 10,000 miles at economic speed, such a ship should be able to accomplish much valuable work in arctic waters *Discovery II*, however, does not carry fishing gear of commercial dimensions, such as the sister ship will presumably employ if, as the British Trawlers' Federation suggests, the survey is accompanied by practical tests on a small scale of the fishing capacity of the grounds explored

It may occasion some surprise to those not acquainted with the present fisheries' situation that a great part of the area to be surveyed lies north of the Arctic Circle The explanation of this rests upon the fact that every year the productive centre of our great sea fisheries tends to move farther north The North Sea, once the most important fishing region, has yielded pride of place to Iceland, while increasing quantities of fish are now being landed from the still more northerly waters off Greenland and Bear Island But with this movement northward the available charts and normal aids to navigation become fewer and less informative, so that our fishing pioneers labour under increasingly difficult and dangerous conditions Thus it happens that substantial expenditure in time and money is incurred even to locate grounds previously visited With capital expenditure mounting on account of the bigger ships needed, and running expenses becoming heavier due to the longer (and unproductive) journeys to and from the fishing grounds, the owners feel that they cannot undertake the desired survey work Nor is it unreasonable, as the Sub Committee of the Committee of Civil Research points out, for the industry to look to His Majesty's Government to provide, in respect of the new fishing grounds, the same type of information as was formerly supplied in regard to the nearer fishing grounds

The expedition of the British Museum to British Honduras to excavate Maya antiquities left England on Jan 23 Owing to the inability of Capt T A Joyce to accompany the expedition this season, it is under the command of Capt E L Gruning He is accompanied by Mr Robert Ashton and Mr E H Nelson The expedition will again start from Punta Gorda, after a short stay at Belize, proceeding up the Mojo River to Pusilhá by canoe and motor tractor Investigations will be resumed at the point at which they came to an end in 1929 Of the six large monoliths discovered last year, two remain to be deciphered and brought back Further excavations will be made in the cave discovered last year It will be remembered that the deposits in this cave, which yielded such a large store of remarkable pottery fragments, suggested that it had been used as a domestic rubbish shute by the inhabitants of a village site above In addition to carrying further the work begun last season, Capt Gruning proposes to examine a large number of ruins on the other bank of the river—an investigation which the topographical conditions suggest should provide much interesting material bearing upon cultural sequences and development in the area as a whole

It is announced that the material obtained by the British Honduras expedition in 1929 will shortly be on exhibition in the British Museum Of this material a considerable proportion consisted of literally thousands of fragments of pottery which have been laboriously sorted, classified, and pieced together in the months which have elapsed since the members of the expedition returned to England The results will well repay close study The quality of the pottery is for the most part remarkable in the fineness both of its texture and finish, while the painted ornament, some of it unique in design, is beautiful in colour and style The reconstruction of so many complete pieces from such a mass of heterogeneous sherds is a remarkable testimony to the skill and patience of the museum staff The variety of style in form and decoration, which will be apparent when the material is seen as a whole, will serve to emphasise its importance as a clue to cultural development and in itself point to the need of a complete investigation of the site Unfortunately, the British Museum itself has no funds for continuing the investigation on this or other sites in British Honduras In previous years the expedition has been financed by donations, £200 a year having been contributed from a fund given to the Museum by Mr John A Roebling, an American benefactor A similar amount has also been contributed by the Colony of British Honduras In appealing for further contributions, the Director of the Museum points out that this is an opportunity for investigating a hitherto unknown culture within the British Empire and that it gives British archæologists a security of tenure not obtainable in the excavation of prehistoric sites in the Old World

The International Union for Pure and Applied Chemistry has now been reconstituted and brings in the German chemical societies under mutually acceptable conditions Before this could be accomplished it was necessary for three of the leading German chemical societies to form a joint committee for international occasions This Verband Deutscher Chemischer Vereine has been able to negotiate with the Union Internationale de la Chemie Pure et Appliquée The new constitution and statutes are given in an article by Prof Haber, president of the Verband D C V in the *Zeitschrift für Angewandte Chemie* of Dec 7 The new title is to be Union Internationale de Chimie, omitting the words pure and applied The new statutes were agreed upon at Scheveningen in June 1929 If there are minor ambiguities in the German translation the French text is to be taken as official German adhesion to the reconstituted Union is subject to the understanding that in its new constitution the International Research Council will not hinder the autonomy and free development of the Union For German international chemical interests, communications may now be addressed to the secretary of the Verband D C V, Herrn Geheimrat Prof Dr Marckwald, Berlin, W 10, Sigismundstr 4

At the general assembly of the International Research Council which was held at Brussels in July 1928, the executive committee of the Council was authorised to approve any modifications which the Unions might desire to make in their statutes so long as these did not conflict with the statutes of the Council At the same meeting a committee was appointed to consider what modifications should be made in the statutes of the Council at the end of the present convention, which is in force up to Dec 31, 1931 This committee met in Paris in September last, and its recommendations are now before the executive committee of the Research Council on which all the Unions are represented The present general secretary of the International Research Council is Sir Henry Lyons, c/o The Royal Society, Burlington House, London, W

To everyone interested in research the report for last year of the British Electrical and Allied Industries Research Association will be very encouraging Not only has substantial progress been made in scientific researches on various important branches of the industry but also the finances of the Association are in a very satisfactory state This was due to the prompt response made by electricity supply undertakings to an appeal for assistance, the automatic reduction of the Government grant being more than compensated by the new subscriptions Valuable researches are being carried on for the Electricity Commission and for the Central Electricity Board Special mention is made of the work done in elaborating methods for measuring the losses which occur in dielectrics when subjected to great electric stresses Methods have been devised for the accurate measurement of the heat transferred from electric cables to the ducts containing them and to the heating of deeply buried cables Researches on the losses in dielectrics at radio frequency are being carried out at the City and Guilds College and at the East London College A very complete résumé of all the available information on the interference of power lines with telegraph, telephone, and radio circuits has been compiled Experiments to clear up difficulties in the practical theory of 'interference' have also been made Researches on the effect of earth returns under all conditions of working have received special attention as they have a very practical bearing on the working of the 'grid' system in Great Britain

In his Friday evening discourse on Jan 24 at the Royal Institution on "Cellulose in the Light of the X Rays", Sir William Bragg stated that when a fine pencil of X rays traverses a fibre of any kind, cotton, hemp, ramie, jute, or such like, the mode of scattering indicates that cellulose is composed, in large part at least, of a mass of small crystals That the same X ray diagram is obtained from all fibres, even from animal cellulose, shows that we are dealing always with one and the same substance It can further be deduced that there is in each crystal a periodicity parallel to the direction of the fibre, and this quantity can be determined exactly The essential feature of the construction for cellulose suggested by both X-ray and by chemical evidence is the long chain of many links The bonds that tie the links together are far stronger than those that tie the chain together, those that keep each of the cellulose chains together are as strong as the bonds in the diamond Indeed, how could a thread carry a suspended weight unless there were great forces in play? But the side to side forces are far from being so strong There seems ground to suppose that bundles of these long chains form 'crystallites', small crystalline masses of which the cellulose is largely composed When the thread is stretched the X rays show that these bundles go more and more into line When the stress is too great the bundles begin to slide past one another, and if the force is too great, they let go and the thread breaks

The Council of the Institution of Electrical Engineers has made the ninth award of the Faraday Medal to Sir Ernest Rutherford The Faraday Medal is awarded by the Council of the Institution not more frequently than once a year either for notable scientific or industrial achievement in electrical engineering or for conspicuous service rendered to the advancement of electrical science without restriction as regards nationality, country of residence, or membership of the Institution

Dr Louis A Bauer, Director of the Department of Terrestrial Magnetism of the Carnegie Institution of Washington since the establishment of the Department on April 1, 1904, retired from this position on Jan 1, last, with the title of director emeritus Provision is being made whereby if his health permit he may carry on studies during the coming year as a research associate of the Institution Mr John A Fleming, associated with Dr Bauer as chief assistant in the Department of Terrestrial Magnetism since 1904, as assistant director for observational and administrative work during 1922 and 1923, and as assistant director in charge of operations since 1924,

continues in charge of the work of the Department with the title of acting director

Dr Friedrich Küstner, director emeritus of the Bonn Observatory, has been made an honorary member of the American Astronomical Society, according to the provision that permits the election of one such member each year Seven other living astronomers have been thus honoured Dyson, Charlier, Turner, Baillaud, Eddington Wolf, and Deslandres Kustner is best known for his detection, in 1888, of the variation of latitude, from observations made with a zenith telescope at Berlin His two fundamental star catalogues, carried out with the meridian circle at Bonn, are unexcelled in accuracy and thoroughness, and are universally regarded as models for this class of work With the comparatively modest equipment of the Bonn Observatory he has carried out a long series of determinations of radial velocities, and has shown that large telescopes are not necessary to secure results of a high order of accuracy As a by product of this work he was the first to determine the parallax of the sun by observing radial velocities of stars

The Rivers Memorial Medal for 1929 has been awarded by the council of the Royal Anthropological Institute to Mr J H Hutton of the Indian Civil Service for his services to anthropology in the field in Assam Mr Hutton is the author of a monograph on "The Angami Nagas", published for the Assam Government, and a frequent contributor to scientific periodicals of notes on the ethnography of the Naga hill tribes He has written the introductions to several of the monographs on the ethnography of the Nagas, published for the Government and written by members of the Civil Service and others, and it is largely owing to his energy and keen interest as director of ethnographical work, in which he has received the full support of the Government authorities, that a large amount of valuable information relating to the Naga tribes has been collected by himself and his subordinates in the course of their official duties

The Frazer Lecture, which was founded as a tribute to the work of Sir James Frazer, and is delivered biennally in turn in the universities with which he has been intimately connected —Oxford, Cambridge, Glasgow, and Liverpool—will be delivered this year at Oxford on Feb 22 The lecturer is Dr P Rivet of Paris, the distinguished authority on the primitive cultures of America The subject of the lecture will be "Civilisation américaine et océanienne" Dr Rivet proposes to be in England for some days, and during his stay will deliver several lectures On Feb 20 he will lecture at the University of Bristol on "Les Grandes Civilisations Andéennes de la République de l'Equateur" On Feb 25 he will be entertained at Cambridge and will deliver a lecture on "Les Races océaniennes en Amérique" On Feb 27 he will be entertained at lunch in London by the Anglo-French Institute on behalf of Sir James and Lady Frazer, and in the evening of the same day will address the Institut Français, when his subject will be "Voyage au Mexique" The following week he will be at Manchester on Mar 5, when he will again give an account of his travels in Mexico, and on Mar 6 will read a paper before a joint meeting of the Anthropological Society of the University of London and the Royal Anthropological Institute at the London School of Economics at 8 P M, his subject being "La Méthode historique et la Méthode évolutioniste en Ethnologie"

On April 5-9, the American Society of Mechanical Engineers will celebrate its fiftieth anniversary, and Mr W H Patchell and Mr L St L Pendred have been appointed to represent the Institution of Mechanical Engineers during the celebrations It was on Feb 16, 1880, in the office of the *American Machinist*, that the preliminary meeting of the Society was held, while the inaugural meeting took place on April 9, 1880, in the auditorium of the Stevens Institute of Technology at Hoboken Prof R H Thurston, as well known for his work for engineering education as for his researches and writings, was the first president, while his immediate successors included such as Leavitt, Sweet, Sellers, Babcock, and Towne, all pioneers in their respective spheres The Stevens Institute is preparing an elaborate pageant depicting the early activities of the Society, a memorial service will be held at the Cathedral of St John the Divine New York, and the subsequent proceedings will be held in Washington and will include a reception at White House It is scarcely necessary to remind our readers that Mr Hoover, the president of the United States, is himself an eminent mining engineer A special feature of the proceedings will be the reading of sixteen papers bearing upon the influence of engineering upon civilisation, each of the papers summarising and evaluating the contributions of engineering to the cultural, social, economic and political life in one of the sixteen selected geographical divisions of the world

Two publications relating to the conference of Empire Meteorologists, held in London in August last, have been received They refer to the agricultural section of the conference, which was arranged at the suggestion of the Empire Marketing Board, and was held under the chairmanship of Sir Napier Shaw The first is simply a general report, running to sixteen pages, which gives details of the organisation of the section and of the resolutions arrived at in regard to future research in agricultural meteorology It also contains various definitions that indicate which, in the opinion of the Conference, are the branches of agriculture particularly affected by weather or climate, and which are the subjects in the domains of the meteorologist and the agricultural research worker respectively Among the resolutions may be noted one which was arrived at by a special committee, namely, that the month is too long a period for summarising, for publication, statistics of agricultural meteorology, and that the week should be used in preference

The second publication is a comparatively bulky volume running to more than three hundred pages, entitled "Papers and Discussions", giving the full substance of all the papers read at the Conference,

and of the discussions that followed them. Since each is followed in addition by a considerable bibliography of recent papers on that particular subject, it will be understood that this volume will prove very valuable to research workers throughout the Empire. The papers cover a wide field, which includes the influence of weather on crops, insect pests, the growth and fruiting of various fruit trees, etc., and the relationship between individual meteorological factors and the physiological processes of plant growth. There is a subject index that facilitates the extraction of particular items of information—a point of some importance to those practical farmers who may be sufficiently up to date in their methods to make use of information of this kind, but have little time for study.

The ninth Annual Report of the Animal Breeding Research Department of the University of Edinburgh, by Prof. F. A. E. Crew, the director, indicates in small compass the great variety of investigations being undertaken by that institution. Apart from many researches in the physiology of sex and reproduction in birds and mammals, studies in subjects bearing more or less directly upon the problems of the farmer and breeder have touched upon all the common domestic animals of Great Britain. The new building which has been designed for the work of the Department is likely to be in full occupation early this year, and this should add greatly to the facilities of the many research workers who make use of the institution. Much has been gained by the attachment of the Imperial Bureau of Animal Genetics, and already the production is forecast of a quarterly bulletin on the breeding of domestic animals, especially of those within the Empire. Through the generosity of Mr. T. B. Macaulay, a new lectureship, with assistantships and maintenance, has been endowed, and a sum of £5000 has been offered for the purchase of a farm, designed to be equipped, stocked, and run as a fully functioning experimental station.

The Report of the British Photographic Research Association for the year 1928–29 has recently been issued. It shows a continued and satisfactory progress, with a few changes in the personnel, as of course is to be expected. In the endeavour to estimate the value of investigational work, there is nothing more deceptive as a guide than the number of communications published, but we cannot help noticing that while three papers have been published, eleven "Private and Confidential Reports" have been circulated to members. We hope that the private and confidential section of the work will tend to diminish by the transfer of what might perhaps belong to it from some points of view, to the published section. Judging merely from some of the titles, it appears that this might well have been done during the past year.

A wireless station for meteorological purposes has been erected in Franz Josef Land by the Soviet Government. A report of the expedition that was charged with the task is contained in a recent issue of the *Weekly News Bulletin* (No. 44) of the Soviet Society for Cultural Relations with Foreign Countries. The icebreaker *Sedov* left Archangel in July 1929. After some difficulty with pack ice, Hooker Island was reached and a landing made. Newton Island and Cape Flora were then visited; eventually Scott Keltie Island to the north of Hooker Island was chosen for the station which was erected during August and put in charge of Prof. O. Schmidt. The *Sedov* pushed north along British Channel and visited Rudolf and Nansen Islands before returning to Europe. Geological and oceanographical results are promised.

Owing to unusual ice conditions in the Ross Sea, Admiral Byrd's American Antarctic expedition is in some danger of being held in the south for another winter. The *Times* reports that Admiral Byrd from his station near the Bay of Whales on the Ross Barrier has sent a wireless message asking for help. His ship, *City of New York*, is unable to force its way south through the pack ice in order to pick up the expedition, and the assistance of Norwegian and British whalers, of which there are several in the Ross Sea, has been asked for. There seems to be about seventy five miles of pack ice lying some two hundred miles north of Admiral Byrd's camp, and offering an obstacle to his ship. Even if the expedition is unable to escape, there should be no danger of starvation, since abundant stores were landed last year and seals are numerous.

Enderby Land in the Antarctic, lying on the Antarctic Circle in about long. 50° E., was discovered by Biscoe in 1831 and was not sighted again until December 1929. To the east of it in about the same latitude, in long. 60° E., Kemp Land, reported in 1833 by a sealer of that name, appears on the maps. Despatches to the *Times* show that the *Discovery* expedition of Sir Douglas Mawson and the *Norvegia* expedition of Capt. Riiser Larsen have both made considerable discoveries by sea and air and have met in the neighbourhood of Enderby Land. Sir Douglas Mawson has rediscovered Kemp Land and charted a new stretch of coast line to the east, which he has named MacRobertson Land. This evidently continues in the direction of Wilhelm Land and marks the continuity of land south of the Indian Ocean. The *Norvegia* on Dec. 22 found land between Kemp and Enderby Lands and charted the coast from long. 55° E. past Biscoe's Cape Ann to long. 43° E. Two weeks later Sir Douglas Mawson's expedition landed on a rocky coast in Enderby Land in lat. 66° 30′ S., long. 53° 30′ E., and found it to be built of ancient crystalline rocks, which proves the continuance of the Antarctic plateau into that area. Several lofty ice free peaks were noted to the south-south west. Many penguins and other sea birds were nesting along the coastal rocks. The frequency of huge tabular icebergs in the vicinity indicates the existence of tongues of the ice sheet not far off and probably to the east.

Among the recent acquisitions of the British Museum (Natural History) are the following. Prof. A. C. Seward, of Cambridge, has presented to the Department of Entomology a large collection of insect galls and gall makers from various localities in Great Britain. The plants upon which the galls were found

belong to some 28 genera and many of the specimens date back nearly to 1860 A correlation of these early records with present day knowledge should therefore render it possible to form some idea of the way in which many species of gall makers have extended their range The recent Oxford University Expedition to British Guiana, for the purpose of studying life in the upper levels of a tropical forest, has handed over some 10,000 insects of various orders as part of the proceeds of its work This collection derives special interest from having been made almost entirely in primitive jungle, as distinct from second growth forest, and from the fact that it includes many specimens obtained in trees at heights of 60 100 feet The value that the common pheasant may sometimes possess from an agricultural point of view is illustrated by a series of 243 larvæ, or grubs, of the St Mark's fly (*Bibio marci* Linn) found in the crop of a hen pheasant, and presented by Mr Mark Crapp, of Liskeard The larvæ of the various species of *Bibio*, of which a number occur in Great Britain, live in colonies in the soil and do a certain amount of damage to the roots of grasses and other plants As a further result of a collecting trip to South Africa last year, the mineral collection has received this month seven lots of material from South Africa The collection of diatoms in the Department of Botany of the British Museum is both in historical value and in size the most important in existence It has recently been enhanced by the bequest of about 12,500 slides which formed the collection of the late Wynne E Baxter This contains nearly 5000 slides from the famous collection of Frederick Kitton and a separate type collection arranged according to Van Heurck's treatise on the Diatomaceæ which was translated by Baxter in 1896

SIR ALFRED YARROW has been elected an honorary member of the Institution of Civil Engineers

IT is announced in the *Times* that the residuary estate of the late Mr George de Arroyave Lopes, which is to go to the Zoological Society of London to form a De Arroyave Fund, will amount to more than £70,000 The Fund is to be applied for the upkeep and improvement of the Zoological Gardens and for the objects of the Society, the only conditions being that the Society hang the portrait of the testator's mother in its board room and maintain the family grave of Mr de Lopes and his own grave

THE Botanical Museum of the University of Zurich has voted the sum of 4000 Swiss francs, distributed over three years, towards a hydrobiological investigation of high Alpine Swiss lakes Candidates for grants should apply to the president of the Commission, Prof Dr Hans Schinz, Biberlinstrasse 15, Zurich 7, from whom the detailed programme of work may be obtained Those of foreign nationality must have spent at least one year at a Swiss university in order to be eligible

THE first photograph of the skull of *Sinanthropus* or Peking man recently discovered in China was exhibited by Prof Elliot Smith at the meeting of the Royal Anthropological Institute on Jan 21 Prof Elliot Smith gave a brief demonstration of the photograph, pointing out the distinctive features to which attention has already been directed in the preliminary accounts of the skull which have appeared in our columns (Dec 28, 1929, p 973) and in the daily Press

A JOINT meeting of the Royal Aeronautical Society and the Royal Meteorological Society will be held on Friday, Mar 14, at 6 30 P M, at which a lecture will be delivered by Dr Fridtjof Nansen on "The Aims and Objects of the Aeroarctic" The meeting will be held in the Lecture Hall of the Institution of Electrical Engineers, Savoy Place, when Lord Thomson, Secretary of State for Air, will take the chair After the lecture a dinner in honour of Prof Nansen will be held at the Savoy Hotel

AT the anniversary meeting of the Royal Anthropological Institute held on Jan 28, the following officers and new members of council were elected for the year 1930–31 —*President* Prof J L Myres, *Hon Secretary* Mr E N Fallaize, *Hon Treasurer* Mr G D Hornblower, *Hon Editor* Mr H J Braunholtz, *New Members of Council* Miss G Caton Thompson, Prof W Le Gros Clark, Dr E E Evans Pritchard, Mr C F Hawkes, Mr T A Joyce, Mr A Keiller, Lord Raglan, and Miss M Tildesley

WE have received No 9 of the present series of the *Recueil des Travaux Chimiques des Pays Bas*, published in August last, which is a complimentary number dedicated to Prof A F Holleman on his seventieth birthday, The volume contains short papers by chemists of many countries and covering a wide range of subjects Some of these give useful summaries of researches carried out by the authors over a series of years

THE Ministry of Health has issued a memorandum (Memo 122 C/T) on the costs at residential institutions for the treatment of tuberculosis The table has been compiled on the same lines as in former years, and the information given should be of assistance to authorities in enabling them to check their expenditure and to take such steps as may be necessary to secure efficient and economical administration of their institutions

WE have received *Technical Paper* No 1 on Water Pollution Research, Department of Scientific and Industrial Research (London H M Stationery Office, 6*d* net), which deals with water softening, the base exchange or zeolite process, and gives a summary of existing knowledge on this subject The report has been prepared by Dr A R Martin under the direction of Prof G T Morgan, in the Department's Chemical Research Laboratory at Toddington

THE semi official Institute of Physical and Chemical Research of Tokyo has published a *Guide* which states that the object of the Institute is to assist industrial development by investigations in pure science It occupies a site of nearly 40,000 square metres in Tokyo and has a capital of £570,000 derived largely from official sources Its expenditure for the year ending Mar 31, 1929, was £67,000, including an annual subsidy of £25,000 from Government Its

staff consists of 256 directly engaged in investigations and about three hundred assistants, some of whom are engaged in experimental work in factories

THE effects of the presence and absence of ultra-violet radiation have been the subject of experiment in the Aquarium of the New York Zoological Society The tests were mostly carried out upon fishes The detailed results are to be embodied in technical publications, but the Annual Report of the Director of the Aquarium states that the benefit of such irradiations under proper control, and the deleterious effect of their absence, were satisfactorily demonstrated They include effects on health, fecundity, and growth of fishes and turtles of various species, as well as various minor effects upon representatives of other groups.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A headmaster of the Euclid Street Secondary School (Co educational), Swindon—The Secretary to the Education Committee, 22 Regent Circus, Swindon (Feb 8) A mathematics master and a chemistry master at the Acton Junior Technical School—J E. Smart, Municipal Offices, Acton, W 3 (Feb 8) A chief assistant under the Scottish Society for Research in Plant-Breeding, for research into virus disease of potatoes—The Secretary, Scottish Society for Research in Plant Breeding, 3 George IV Bridge, Edinburgh (Feb 15) An oil seeds specialist in the Madras Agricultural Department—The Secretary to the High Commissioner for India, General Department, 42 Grosvenor Gardens, S W 1 (Feb 22) A senior and a junior geologist and a junior mineralogist in the department of the Geological Survey of Southern Rhodesia—The Secretary, Office of the High Commissioner for Southern Rhodesia, Crown House, Aldwych, W C 2 (Mar 31) A junior assistant under the Directorate of Ballistics Research of the Research Department, Woolwich—The Chief Superintendent, Research Department, Woolwich, S E 18 A temporary science mistress at the Borough Polytechnic Institute—The Principal, Borough Polytechnic Institute, Borough Road, S E A Secretary of Clifton College — The Secretary, Clifton College, Bristol

Our Astronomical Column.

Astro-Photography of the Future —The French journal, *L'Illustration* for Dec 21 contains an article by Dr G W Ritchey, late of the Yerkes and Mount Wilson Observatories, entitled, " De Nouveaux Firmaments Dévoilés par l'Astrophotographie " The article is enriched by some admirable large scale reproductions of Dr Ritchey's beautiful photographs of nebulæ taken with the 60 inch reflector of Mount Wilson Observatory, and is itself mainly a descriptive and speculative commentary on those photographs Those who attended Dr Ritchey's lectures in London a few years ago will remember with pleasure the numerous excellent lantern slides with which they were illustrated In the course of some reflections on the future possibilities of astro photography, Dr Ritchey remarks that, in spite of many examples of the achievement of the seemingly impossible, if to day an experienced astronomer should venture to affirm that in a dozen years our knowledge of the universe would be enormously increased by the employment of photographic telescopes a hundred times more powerful than our present ones, he would be considered a heretic Nevertheless, adds Dr Ritchey, this is a possibility capable of immediate realisation The super telescopes which he foreshadows will give us large scale photographs of thousands of spiral nebulæ in each stage of their development, with details of structure more delicate than those visible in existing photographs of the Andromeda nebula By their comparison and classification there will gradually but surely become unveiled the story of the evolution of these immense stellar systems of space

Washington Naval Observatory —The Report of this observatory for 1929 has just come to hand The eclipse expedition to Iloilo, Philippines, "was favoured with almost perfect weather conditions" Eighty photographs were taken, in addition to sketches and motion pictures taken from aeroplanes Appreciation is expressed for the help given by Prof W A Cogshall, of Indiana University, who joined the expedition

The American Ephemeris, like the British Nautical Almanac, is introducing several changes in 1931 The mean equinox of the beginning of the year is used for the longitude and rectangular co ordinates of the sun In the prediction of eclipses the sun's longitude from Newcomb's tables is increased by 1 5", and in the prediction of eclipses and occultations the moon's longitude is increased by 7" A new zodiacal catalogue is in progress of formation which will contain all stars down to magnitude 7 0 that are liable to occultation The 26 inch equatorial was used for observations of occultations of double stars and of the satellites of the planets, theoretical researches have also been made on the satellites of Mars and Saturn

An interesting graph is given of sunspot activity since 1923, when the minimum occurred, the increase in activity in 1925 was very rapid, the highest maximum occurred before the middle of 1926, a second, but lower, maximum occurred just two years later There is a decided depression between the two maxima, the curve resembles that of two sunspot cycles earlier

Preparations are being made for observing Eros at its coming near approach, and many observations have been made of the stars selected as comparison stars

Radial Motions of the O-type Stars —Prof C D Perrine discusses the radial motions of these stars in *Astr Nach*, 5672 After *correcting* for solar motion, he finds that the stars without emission lines show a decided positive velocity, while those with emission lines show negative velocity The proper motions do not give any support to the view that the difference is in the space velocities of the stars, and he concludes that it arises from internal motions of expansion and contraction He reached a similar conclusion concerning the planetary nebulæ in *Astr Nach*, 5670 He further suggests that the variable radial velocity which has been found in some of these stars, and ascribed to orbital motion, may be due to alternate expansion and contraction This is held by many to be the explanation of the shift of spectral lines in the Cepheid variables Prof Perrine also suggests that the planetary nebulæ and the *O* and the *B* type stars form a progressive series of objects This, however, does not seem to harmonise with his conclusion that all the planetary nebulæ are the relics of former novæ

Research Items

New Light on Drake's Voyage.—Two documents discovered by Miss E. G. R. Taylor in the British Museum throw much light on the plans of Drake's voyage of 1577. One of these documents, reproduced in part with an article in the *Geographical Journal* for January, is a draft plan for the voyage. Unfortunately, the document is mutilated, but careful examination reveals that the ships were to go and return by Magellan's Straits, that unknown shores not in the possession of any Christian prince were to be visited, and that the voyage was to be extended to 30°. Miss Taylor believes that the coast to be examined was not that of western America, which was already in Spanish possession between 40° S. and 35° N., but that of Terra Australis as shown on the Ortelius map of 1570. This coast ran north-west from the Strait of Magellan across the Pacific to the Moluccas. The second document is John Winter's report made on his return to England after losing touch with Drake in the South Seas. Winter's report shows that the westerly winds of the South Pacific made a westerly course impossible for him and no doubt encouraged Drake to turn north to harry the Spaniards and accept the alternative plan of seeking for the Strait of Anian. On his failure to find this strait in lat. 48° N., he turned to his original destination of the Moluccas.

Birds of the *Adventure* and *Beagle*.—When H.M.S. *Adventure* and *Beagle* were sent on a survey to the Strait of Magellan in 1826, the officers were instructed to collect rare, new, or interesting objects of natural history. Capt. King faithfully carried out the order, sending a first collection of 78 specimens of birds from Rio de Janeiro in 1827, and bringing with him on his return in 1830 a further collection, the numbers of which are unknown. These collections contained many new species of birds, and in view of the doubt which has existed as to the final resting-place of the type specimens, Surgeon Rear-Admiral J. H. Stenhouse has given short descriptions of the twenty-one specimens now in the Royal Scottish Museum in Edinburgh (*Scot. Nat.*, p. 181, 1929). Seven appear to be types or co-types of species described as new, but of these three have since been recognised as synonymous.

American Chipmunks.—The "North American Fauna" series of the Biological Survey of the U.S. Department of Agriculture continues its useful course with a revision of the chipmunks. Some impression of the amount of concentrated observation in present-day systematics may be gained from the fact that Arthur H. Howell, in writing this monograph, had at his disposal 1349 specimens of one genus with one species and 13,205 of another with 16 species. The result has been an increase in the number of geographical races recognised. Where *Tamias*, last revised in 1886, had two races, there are now five in a compact species, and where *Eutamias*, revised by Allen in 1890, had 23 forms, 60 have now been recognised. Something of the effect of diverse environmental conditions is suggested by the compactness of the eastern genus, and the extraordinary breaking up of the western genus into a multitude of forms. Interesting accounts are given of burrowing and nesting, food storing and hibernation, breeding and feeding habits, and the descriptions of the various races are marked by a careful discrimination between summer and winter pelages. The chipmunks, particularly the western forms of the mountains and wildernesses, are of little economic significance, but they are familiar to most Americans, since they approach townships and cities with much more freedom than the native squirrel of Great Britain.

Crabs from Panama.—Mr. Lee Boone, member of the research staff of the Tropical Research Station of the New York Zoological Society, describes several very rare crabs in his paper "A Collection of Brachyuran Crustacea from the Bay of Panama and the Fresh Waters of the Canal Zone" (*Bulletin of the American Museum of Natural History*, Vol. 58, Art. 11, New York, 1929). The crabs were collected by Dr. Willard G. Van Name and his party, during a trip to the Isthmus of Panama and Pearl Islands in the spring of 1926, several hundreds being obtained, all of great interest. Among other rarities were two specimens of *Pitho quinquedentata*, one a female which is the first seen, as hitherto only two males were known, and a very fine example of the 'periscope-eyed' crab, *Euphylax dovii*, one of the Portunidæ. New records were obtained of the large fresh-water crab *Pseudothelphusa richmondi* showing an extended southern range. In this species the young, as in other Potamonidæ, are like the parent at birth, omitting all larval stages. In the present case the abbreviated life-history is probably correlated with the fact that in the dry season there is frequently no water in the stream beds in which the crab makes its home. The paper is illustrated by good photographs.

Studies on *Pectinatella*.—C. M. Brooks (*Proc. Acad. Nat. Sci. Philadelphia*, vol. 81, 1929) records observations on *Pectinatella magnifica*, the largest of the colonial fresh-water Polyzoa, the colonial mass of which sometimes exceeds two feet in diameter. This large gelatinous mass is hollow in the centre and there live flatworms, protozoa, snails, and crustacea; the flatworms are especially numerous and their eggs also are almost always to be found. The young flatworms appear about the time the statoblasts of *Pectinatella* break open and they devour the polypides in large numbers. The formation of statoblasts in *Pectinatella* begins in early autumn and continues until stopped by cold weather. The statoblasts are the chief means of distributing the species. When they first appear they are covered with a layer of jelly which prevents them clinging to the parent colony and they are readily dislodged and swept away by currents in the water, the zone of air-filled cells keeping the statoblast afloat. The covering of jelly soon decays and the hooks then exposed attach the statoblast to floating debris or to other objects. The statoblast develops steadily from the time it is fully formed until the polypide is produced, but the rate of development depends largely on the temperature. The author adds details of the anatomy of the polypide and states that scattered through the mass of food in the stomach are large nuclei, vacuolated and in degeneration, of cells which have migrated from the wall of the stomach possibly to aid in digestion.

Errors in Precise Levelling.—Apart from movements of the earth's crust, considerable errors in precise levelling may occur in several ways. Movements of the peg or bench mark during the night or between successive seasons is a source that cannot always be obviated. The small but appreciable error due to the use of wooden staves is to be prevented in the survey of India in future by the use of invar staves. Irregular refraction may be serious on a long continuous gradient. Lastly, the crossing of wide unbridged rivers involves a great loss of accuracy. In *Professional Papers*, No. 22, Survey of India,

Capt G Bomford discusses the errors connected with the last three sources Recommendations are made for levelling across unbridged rivers in the primary net Micrometer eyepieces should be used Crossings should be made at a number of sites covering some miles of the banks Sites below river junctions should be avoided Directions are given for the use of sites in the middle of the river when the width renders this necessary The paper discusses many points of great importance

Properties of β-Particles —Collisions between β particles and electrons or atomic nuclei are less easy to study than those of α particles, but two recent investigations indicate that the correct laws of interaction have yet to be derived theoretically One paper on this subject appears in a recent issue of the *Annalen der Physik* (No 7), by O Klemperer, and deals with the scattering of electrons with energies equivalent to 9 kilovolts and 18 kilovolts respectively These were drawn from a hot filament, and examined by a Geiger electrical counter after passage through thin films of celluloid, beryllium, or aluminium, their angular distribution could not be reconciled with any of the usual laws which were tried The other paper on the same subject is by E J Williams and F R Terroux, in the January issue of the *Proceedings of the Royal Society*, and is concerned with the tracks of rather faster β particles in a Wilson cloud chamber The results show that the classical theory gives only the order of magnitude both of the primary ionisation produced and of the frequency of production of branched tracks, the observed values being appreciably greater than the classical values, and following moreover a different law of variation with the velocity of the particle The deflection of the β particles in branch collisions does correspond, however, approximately to the momentum of the branch, contrary to the results found by Prof C T R Wilson for slower rays

Radioactive Constants —The question of the invariability of the decay constants of radioactive elements has been discussed by Mme P Curie in two papers in the September number of the *Journal de Physique* In the first of these, commenting on a previous paper by L Bogojavlensky (see NATURE, June 8, 1929, p 872), she points out that very stringent precautions must be observed before the existence of any change in a constant with position on the earth's surface can be regarded as established In the second, she describes briefly a number of experiments which have been made by her, or under her direction, in attempts to influence the normal course of radioactive disintegration These have been made upon radium, radon, and polonium, by exposure to various types of radiation, and although some of the observations have still to be accounted for in detail, Mme Curie believes that in no case do the results obtained furnish any certain evidence of departure from the generally accepted laws

Electrons and Protons —A theory of positive electricity has been put forward by Dr P A M Dirac in the January number of the *Proceedings of the Royal Society* The relativity quantum theory of an electron leads to a wave equation which possesses solutions corresponding to negative energies—the energy of the electron of ordinary experiment being reckoned as positive—and although there are serious difficulties encountered in any immediate attempt to associate these negative states with protons, the existence of positive electricity can be predicted by a fairly direct line of argument Since the stable states of an electron are those of lowest energy, all the electrons would tend to fall into the negative energy states—with emission of radiation—were it not for the Pauli exclusion principle, which prevents more than one electron from going to any one state If, however, it is assumed that "there are so many electrons in the world that all the states of negative energy are occupied except perhaps a few ", it may be supposed that the infinite number of electrons present in any volume will remain undetectable if uniformly distributed, and only the few 'holes', or missing states of negative energy will be amenable to observation The step is then made of regarding these 'holes' as '*things of positive energy*' which are identified with the protons A difficulty now arises in ordinary electromagnetic theory which apparently has to cope with the presence of negative electricity of infinite density, this is met by supposing that for ordinary purposes volume charges must be measured by departures from a 'normal state of electrification', which is "the one where every electronic state of negative energy and none of positive energy is occupied" The problem of the large mass of the proton, as compared with that of the electron, is not discussed in detail, but a possible line of attack is indicated Dr Dirac has included the minimum of mathematical analysis in this paper, which can be followed in all essential points by anyone acquainted with the principles of the quantum theory

Relation between Specific Heat and Temperature —The *Atti della Pontificia Accademia delle Scienze* (*Nuovi Lincei*) for 1929 contains a communication by A Denizot on a relation existing between specific heat and temperature This author has previously directed attention to the formula, $c = a \log T$, according to which the specific heat is proportional to the logarithm of the absolute temperature This expression is purely empirical and holds only for solid elements. If the values of a are plotted as ordinates against the atomic numbers N as abscissæ, a curve is obtained which is probably continuous under certain conditions and extends at one end to sodium (N 11) and lithium (N 3), and at the other to bismuth (N 83) There is, however, a gap left by the rare earth elements (N 56 72), and the values for boron, potassium, and nickel do not fall on the curve Although no theoretical foundation exists for the curve, yet the marked agreement shown between the calculated and observed values of the specific heats for most of the elements seems to justify its use for calculating the specific heats of the rare earth elements, zirconium, etc, and also the atomic weights of the recently discovered elements, masurium, florentium, and rhenium

Gibbs's Absorption Equation —The December number of the *Journal of the American Chemical Society* contains a paper by McBain and Du Bois in which experiments on absorption in a liquid gas interface, supplementing those already noticed in NATURE (120, p 819, 1927) are described The results, it is claimed, support the conclusion arrived at in the earlier experiments that the surface of an ordinary solution is a unimolecular surface layer of orientated molecules which serve as points of support for the growth of chains of orientated molecules relatively far into the solution, such chains being evanescent, constantly breaking up as a result of thermal vibrations and constantly being replaced The absorbed amount can be several times that which is compatible with the well known equation of Gibbs When a bubble passes through a solution of a simple substance, it can carry with it from two to eight times as much solute as is predicted by that equation, and from two to four times that which can be accommodated in a monomolecular film of closely packed, vertically orientated molecules It is suggested that the use of Gibbs's equation to calculate absorption is artificial.

Insects Infesting Stored Cacao [1]

THE Empire Marketing Board, in establishing a Committee on Infestation of Stored Products, has recognised the importance of dealing with the losses, occasioned both in transit and storage, by insect and other damage to a wide range of foodstuffs By means of a series of grants made to the Imperial College of Science, the Board has enabled that institution to establish at Slough a special laboratory for stored products research At present, attention is being mainly concentrated on the insect problems affecting cacao and dried fruits, and on fungus damage to cacao and copra This work is under the general direction of Prof J W Munro, and, as experience and facilities increase, it will doubtlessly embrace the study of other stored products in addition to those mentioned

A report on insect infestation conditions prevailing in cacao stores in certain of the London docks and wharves, has been prepared for the Marketing Board's Committee on Stored Products by Messrs J W Munro and W S Thompson This shows that the prevention and control of the losses at present occasioned by cacao insects can only be attained by co operation on the part of all concerned, since the infestation occurs throughout all stages of the cacao industry

The problem of insect infestation in stored cacao has three main aspects, namely, (a) in the exporting country, (b) in wharves and warehouses of the importing country, and (c) in the cocoa and chocolate factories of the importing country Cacao insects, for example, may enter the produce in the exporting country and their descendants eventually become transferred to chocolate factories far inland in the importing country This may result in the occurrence of such insects in boxes of manufactured chocolates which may thus reach the consumer Furthermore, certain cacao insects may affect other products stored in proximity to cacao and considerably reduce the value of such products

The chief insects infesting cacao belong to three species The moth *Ephestia elutella* Hb is the most important, and its larvæ attack not only cacao beans but also a great variety of other stored products, including biscuits, figs, chocolate, many kinds of grain, dried fruits, etc It is, consequently, an insect of great economic significance and is very widely distributed The larvæ of another small moth, *Corcyra cephalonica* Staint, are less harmful, since they only occur in small numbers Like the preceding species, it has become widespread, although it was probably originally a pest of rice and has later taken to living on other products The third species is the Anthribid beetle *Aræcercus fasciculatus* De G, the larva of which eat out the endosperm of the cacao beans It is more especially an enemy of nutmegs and only appears to be a serious cacao pest in the Gold Coast

The results of Messrs Munro and Thomson's investigations in London docks and warehouses show that the above species of insects are all found infesting the cacao on arrival from overseas Cacao received from all exporting countries indicates that infestation takes place in those countries, and if remedial and control measures are to be effective they must be carried out at the sources of the trouble In Great Britain it is obvious that whatever measures may be taken to clean up infected buildings, the latter will be liable to become reinfested from fresh cargoes constantly coming in from abroad

Special attention is being given to the *Ephestia* in order to ascertain the life cycle and behaviour of the insect under varying warehouse conditions Its responses to heat, cold, fumigants, and other treatments are being tested, and various experiments have been, and are being, conducted relative to the de infestation of affected buildings where consignments are housed Under present conditions, clean cargoes stored in the warehouses are open to attack, and it is evident that the problem requires concerted action both by the exporting and importing countries These facts are fully recognised, and there is little doubt that now investigations have been initiated, we can look forward to a solution of at least some of the outstanding problems A D I

Field Strength in Broadcasting and Receiver Efficiency

IN connexion with the field strength produced at various places by a broadcasting aerial, the paper on signal strength, by J H Reyner, published in the *Journal of the Institution of Electrical Engineers* for January, will be found of interest Measurements were made in Cornwall of the field strength due to the broadcasting station 5XX at Daventry by means of a simple portable equipment consisting of a screened local oscillator and a sensitive micro ammeter

This equipment enabled the actual pressure in millivolts set up in a portable experimental aerial by the radiations from 5XX to be accurately measured The effective height of the aerial being known, it was possible to convert the readings into field strength values in millivolts per metre

The first set of readings was taken at selected points in Cornwall The contour lines obtained seemed to indicate that the coast line was exercising a marked absorbing effect, the field strength at Plymouth and Newquay being only about one-third that at Launceston In the Perranporth district, the field strength on the coast line was only about half that on the hill-top about two miles inland The masts of the Bodmin beam station were visible from the hill top and this suggested that it possibly cast a radio shadow Subsequent experimental results afford strong evidence of this shadow

The region of bad reception extends almost in a direct line from Daventry through Bodmin as far as Redruth, the distance between the latter two towns being about 25 miles Surrounding this area of low signal strength is a ridge of good reception For example, as one goes out towards the coast from Truro, the signal strength first rises on either side and then falls rapidly as the coast line is approached The Bodmin beam station was erected some years ago, but no complaint seems to have been made hitherto of any shadow being cast by it

There is little doubt that with an accurate method of measuring how a radio receiving set fulfils its functions there would soon be a great improvement in their design Now that the field intensity of the radiation from a broadcast station can be readily measured, simple methods of testing sets experimentally will most probably soon be devised

In a paper read to the Institution of Electrical Engineers on Jan 15, H A Thomas, of the National Physical Laboratory, gave a method of measuring the overall efficiency of a receiver The ultimate aim of

all measurements of the constituent parts of a receiver is to obtain the relationship between the input supplied to it and the output it gives This is the most important of the tests, but it is most difficult to obtain accurate results

In making the tests use was made of the screened oscillator cabin at the laboratory, which has a mercury sealed trap door, and the long copper ventilating pipes of which are provided with three copper gauze baffles which screen unwanted radiation completely The apparatus described covers a wave length range from 5 metres to 30,000 metres

The results of tests on four receivers of widely different type are given The experiments show that the overall properties of any receiver can be specified when the input voltage required at a definite modulation percentage to produce a definite standard output signal is known at all wave lengths within the desired range The selectivity of the receiver is the variation of the sensitivity in the neighbourhood of certain fixed wave lengths The distorting properties in the audio frequency stages have also to be measured If it is only desired to determine the range of a receiver with respect to a particular transmitting station, two characteristic curves suffice The work carried out has been done for the Radio Research Board

Fishery Investigations off Iceland

THE Scientific Report of the North Western Area Committee for 1926–27 (Rapport Atlantique, secteur Nord ouest, 1926–27 Conseil Permanent International pour l'Exploration de la Mer May 1929), by Prof Johs Schmidt, contains four papers, the first and fourth on the haddock and plaice respectively, the second and third being shorter papers dealing with bottom faunas, by R Spärk, and the age composition of the stock of cod in East Iceland fjords, by Arni Fridriksson

Dr Harold Thompson's work on the haddock, "General Features in the Biology of the Haddock (*Gadus æglefinus* L) in Icelandic Waters in the Period 1903–1926", and Dr Å Vedel Tåning's "Plaice Investigations in Icelandic Waters", are both of great importance These works deal with the stock on the feeding grounds, age composition, rate of growth, and various biological considerations Both fishes inhabit natural sub areas of the Icelandic plateau For the haddock, two main regions are differentiated, one to the north and east where the coasts are exposed to the polar current, and one to the south and west which is exposed to the warmer Atlantic stream, spawning taking place in this warmer region with a maximum in April, the fish being larger at the same age than those from the north east It is, however, only the bottom stages of the haddock which are here described, as the eggs and larval forms have been fully dealt with by Johs Schmidt (*Cons Internat Rapp et Proc Verb*, vol 10, 1902–7, No 4) The otter trawl is shown to be efficacious and trustworthy for sampling the haddock shoals Growth rates are calculated from the annual zones in the scales

It is assumed, and the assumption is confirmed by biological evidence, that the Icelandic haddock are a self contained stock cut off from interchange with those of other grounds by deep water The first year haddock, the product of the spawning season, like those in the North Sea, probably remain in fairly deep water, later moving nearer the coast for feeding Except the Faroe haddock, those from Iceland grow more rapidly than any in the East Atlantic It is thought that the feeding conditions probably account for this, although so far only a beginning has been made in research of this kind Sand eel is shown to be largely eaten and rapid growth is then effected. The Icelandic haddock spawn at an age of at least one year older than is the case with those from the North Sea

Dr Å Vedel Tåning's work on the plaice deals with spawning and larval forms as well as with the adults Spawning continues from February until May with a maximum in March and April and takes place chiefly in the warmer water of the south and west, the late spawning having a great influence on the rate of growth The maximal growth is found on the western part of the south coast There is a marked decline in the growth along the south coast round to the east coast coinciding with the fall of temperature Temperature and length of summer are shown to be of great importance for the rate of growth in the plaice in Icelandic waters, and probably these factors influence the rate of growth of plaice generally Unlike the haddock, the Icelandic plaice has a higher total number of vertebræ than other known forms, and also varies much in this respect in the Icelandic area itself

University and Educational Intelligence

CAMBRIDGE —The Gordon Wigan Prize in chemistry for 1929 has been awarded to C G Lyons, Trinity Hall, for a dissertation entitled "Thin Films, their Properties and Structure"

Applications for the John Lucas Walker studentship, the holder of which has to devote himself to original research in pathology, are invited and should be sent before July 1 to the professor of pathology The studentship is of the annual value of £300 and is tenable for three years Applications for the Gwynaeth Pretty studentship, the holder of which has to devote himself to original research in the etiology, pathology, and treatment of disease, are also invited, they should be sent before July 1 to the professor of pathology The studentship is of the annual value of £200 and is tenable for three years

The managers of the Nita King Research Scholarship for the encouragement of original research in the etiology, pathology, and prevention of fevers, invite applications from candidates, these should reach the professor of pathology before Feb 28

The governing body of Emmanuel College invites applications for a research studentship which will be awarded in July next Applications (with evidence for a proposed course of research) must reach the Master of Emmanuel College not later than June 30 Preference will be given to candidates who have already completed one but not more than two years of research The studentship has a maximum annual value of £150, and is normally held for two years

LEEDS —M G B Howarth, senior research assistant on the staff of the Joint Research Committee of the Institution of Gas Engineers and the University of Leeds, has been appointed chief chemist to the Newcastle-upon Tyne and Gateshead Gas Company Mr. Howarth was awarded a University scholarship in 1920, and since then has had varied research experience on the works and in the laboratory at Birmingham and Leeds, dealing with blue and carburetted water gas plants, waste heat boilers, aeration of burners, and the products of combustion of gas appliances

'PARENT TEACHER' associations have been at work in the United States for more than thirty years, striving to bring about closer co-operation between home and school No similar movement elsewhere

has attained the volume represented by the member ship roll of a million and a half of the National Congress of Parents and Teachers of the United States, entirely independent, as it is, of State direction In 1927, however, sufficiently widespread interest had been aroused in other countries to justify the organisation of an International Federation of Home and School This was accomplished at Toronto in con nexion with a meeting of the World Federation of Education Associations, the declared object being "to bring together for conference and co operation all those agencies which concern themselves with the care and training of children in home, school, and community, and with the education of parents to meet these responsibilities" Twenty two countries are represented on the board of management, the first action of which was to undertake a survey of the present situation Some of the salient features revealed by reports received from thirty three countries are recorded in an article by the president of the Federation, published in the November issue of *School Life*, the organ of the United States Office of Education From this we learn that next in size and seniority to the American Congress of Parents and Teachers is a West Australian federation, which concerns itself specially with the provision of playing fields and other matters of importance to the physical welfare of school children The movement was introduced into Canada in 1916 and quickly spread from Ontario to other provinces Here, too, special emphasis is laid upon improvement of school con ditions affecting the health of pupils In almost every country of Europe systematic attempts are, it is found, in progress to establish conscious community of purpose and co operation in home and school

THE International Federation of University Women celebrated its tenth anniversary and held its fifth conference at Geneva last August Some five hundred delegates from thirty one national associations were present Among the matters discussed in the course of the proceedings, which lasted seven days, was "The Value of Research" Madame Ramart Lucas from the Sorbonne contributed a survey of "The Creative Effort of the Chemists", and Dr Luise Lammert, who, after a year of study in Australia as holder of one of the Australian university women's fellowships, is working at the Leipzig Meteorological Institute, gave an account of solar radiation observa tions, including her own researches in Australia The Federation's project for the establishment of inter national fellowships has not hitherto met with the encouragement it seems to deserve, the capital, contributed by eighteen associations, amounting to less than £4000, whereas the sum required to endow one fellowship is £5000 The Carnegie Endowment for the Promotion of Peace has marked its appreciation of the Federation's efforts by granting 5000 dollars to be used for travelling expenses Among resolutions adopted at the conference was one providing for assistance in the translation of scientific works A scheme was formulated for utilising and co ordinating for this purpose the linguistic and technical knowledge of the Federation's members In that part of the conference report relating to the work of the various national associations, their activities are described under the following heads encouragement of in dependent research work, stimulation of interest in national and municipal policy, social service, in telligence service, assistance towards finding employment, facilities for social intercourse, educational and cultural work, and other activities The headquarters of the Federation are at Crosby Hall, Cheyne Walk, London, S W 3

Historic Natural Events.

Feb 2, 1282 Severe Winter —Stow records that "From Christmas to the Purification of our Lady [Feb 2] there was such a frost and snow as no man living could remember the like wherethrough five arches of London Bridge were borne downe and carried away by the streame, and the like hapned to many other bridges in England And, not long after, men passed over the Thames between Westminster and Lambeth dryshod" The frozen Thames was used as a highway, and the damage to the bridges was caused by the break up of the ice The winter was also severe in Europe, and at the end of February such heavy snow fell in Austria that many houses could scarcely be seen The melting of the snows caused great floods, and Paris was inundated by the Seine

Feb 2, 1887 Drought —In January 1887 a great area of high pressure lay over Europe, and in February this moved westward over England In London a drought began on Feb 2, the first of 17 consecutive days without rain In March the anticylcone moved still farther west, and until the end of August with few interruptions pressure remained abnormally high over the Atlantic west of Ireland The year 1887 was consequently very dry, over the British Isles as a whole the rainfall was the smallest on record since at least the beginning of the nineteenth century, though in south east England the drought was less severe than in 1921 The level of Lake Derwentwater fell lower than ever previously recorded, at Maresfield, Sussex, threepence a pail was paid for water, and at Langho, near Blackburn water was brought in cans like milk and strictly rationed by the station master

Feb 4, 1579 Snow —Holinshed records that on Feb 4, and the following night "fell such abundance of snow, that in the morning, the same snow was found in London to lie two foot deep in the shallowest and otherwise, being driven by the wind very boisterous in the northeast, banks one ell or a yard and a half deep In the which drifts of snow, far deeper in the country, many cattle, and some men and women were overwhelmed and lost It snowed till the eighth day of that month, and freezed till the tenth, and then followed a thaw with continual rain a long time after, which caused such high waters, and great floods, that the marshes and low grounds being drowned for the time, and the water of the Thames rose so high into Westminster Hall, that after the fall thereof, some fishes were found to remain in the said hall"

Feb 5, 1783 Earthquake —The series of great Calabrian earthquakes beginning on Feb 5 are of interest as the first to be carefully studied There were six great shocks, the strongest being those of Feb 5 and Mar 28 The meizoseismal areas were all small, one town being ruined, while another a few miles away escaped damage Besides being shallow, the focus oscillated to and fro over a distance of 60 miles from Messina to Girifalco By Oct 1786, 1186 after shocks were felt at Monteleone

Feb 5 and 7, 1892 Low Temperature —The lowest temperature ever recorded on the earth's surface was -90° F at Verkhoyansk, Siberia, 200 miles from the mouth of the Lena River

Feb 7, 1921 Drought —From February to October 1921 barometric pressure was above normal over the whole of Europe except the north of Scandinavia, over the United States, and most of Asia These nine months, and the year as a whole, were exceptionally dry over a large part of the northern hemisphere In London, the drought began on Feb 7, and no

appreciable rain fell until Feb 25. The year was not especially dry in Scotland and Ireland, but in England it was the driest since at least the beginning of the nineteenth century, in parts of east Kent the rainfall was less than half the average, and at Margate the total rainfall for the year was only 10 inches In July the flow of the River Thames at Teddington fell to less than one third of the normal July flow In western Europe the drought was equally severe, in Belgium and northern France it was without precedent in historic times, Switzerland and northern Italy suffered severely, and in the Trentino the water of one of the lakes fell so low that a small island appeared for the first time since the great drought of 1806 In Russia the harvest failed, causing wide spread famine and many deaths

Feb 8, 1843 **Earthquake**—By the destructive earthquake of Guadeloupe, Pointe à Pitre, the principal town and port of the island, was reduced to a heap of ruins The shock was felt in Barbados and along the coast of British Guiana, so that the disturbed area must have contained at least one million square miles The wharves of Pointe à Pitre subsided throughout their length, in one place by about a foot

Societies and Academies

London

Royal Society, Jan 23—**Lord Rayleigh** Normal atmospheric dispersion as the cause of the 'Green flash' at sunset, with illustrative experiments (see NATURE, Jan 25, p 144)—**F W Aston** The photometry of mass spectra and the atomic weights of krypton, xenon, and mercury The relative abundance of isotopes can be deduced from the photometry of their lines in mass spectra with sufficient accuracy for a preliminary survey Numerical results are given for the six isotopes of krypton, nine isotopes of xenon, and seven isotopes of mercury The 'isotopic moment' of an element is defined and its value given for these three elements Atomic weight of mercury determined from the abundance results is in good accordance with the accepted value, those for krypton and xenon suggest that those deduced from the densities are about 1 per cent too low—**P A M Dirac** A theory of electrons and protons It is proposed that nearly all the states of negative energy are occupied, so that an electron in a state of positive energy cannot jump into them, by the exclusion principle A state of negative energy that is not occupied may then be identified as a proton, as it will appear to have a positive energy and positive charge (see also p 182)—**R V Southwell** and **L Chitty** On the problem of hydro dynamic stability (1) The paper deals with stability of steady shearing motion in a viscous fluid The method of normal co ordinates appears to be satisfactory for infinitesimal disturbances Within the range of 'Reynolds' number' covered, all normal disturbances have a decreasing time-factor, which depends on Reynolds' number in an extremely complicated way The looped diagrams representing this dependence have no counterpart in ordinary problems of vibration theory—**T E Stern** Some remarks on the conduction of electricity in metals and upon allied phenomena There are two classes of phenomena (1) Those associated with the flow of electricity in closed circuits, to be investigated only by making use of transport theories, and (2) those associated with insulated conductors, to be investigated by general equilibrium theories Various consequences of this difference—such as difference between cooling effects of evaporation of electrons from insulated and from uninsulated conductors—are investigated Special phenomena arising in case of non isotropic conductors are considered—**A Harvey** The Zeeman effect in the band spectrum of helium (2) Estimates are given of magnitudes of (unresolved) Zeeman patterns in He_2 bands of type $^3D \rightarrow 2P\ ^3\Pi$ Effects are widely different for different initial terms $D\epsilon$, $D\pi$, and $D\Delta$, and appear to be closely related to uncoupling of electronic orbital angular momentum L from the inter nuclear axis A few observations on the singlet system were possible, results being generally similar to those for the triplet system

Geneva

Society of Physics and Natural History, Oct 24—**T. Tommasina** Experimental proof, in the heat radiation, of dynamic ultra red rays A double radiometer, revolving in opposite directions, is placed under a triple glass wall, in order to eliminate the direct action of heat With a previously heated pad of cloth, or piece of wood charcoal, coke, or anthracite, there is an immediate rotation of the vanes The author concludes from this that heated black bodies emit penetrating radiations—**R Matthey** The chromosomes of saurians The author has established the chromosome formula of ten species, representing eight families A classification based on the chromosome formula fits in fairly well with modern systematics—**E Briner** and **A Rivier** The chemical action of electric discharges, the influence of the electrodes on the production of nitric oxide by the arc Relying upon electronic theories, more especially on the laws regulating the electronic emission of solid bodies, the authors have realised, using appropriate material for the electrodes, marked improvements in the chemical yield of the electric arc in the fixation of nitrogen in the form of oxide

Nov 7—**E Cherbuliez** and **St Ansbacher** The physiological presence of copper in certain organs in the higher animals A very exact method of estimation has shown the presence of copper in the organs of the higher animals The liver and the spleen are much richer in this element in the newly born than in the adult, in the tuberculous guinea pig the proportion of copper is increased in the liver and reduced in the spleen These facts suggest a hitherto unsuspected physiological rôle for copper—**G Tiercy** Generalisation of the Plantamour method for the measurement of the error of compensation of chronometers The Plantamour method, applied at Teddington, Besançon, and Geneva, has been proposed by Plantamour for the case of three thermal periods The author shows that it also applies in a very simple manner to the case of n periods—**R. Wavre** Complement to the theory of planetary figures The author, by a rigorous and short method, had obtained a system of theoretical relations giving the free surface of fluid stars in slow rotation Wishing to pass from theory to practice, he puts these relations in a form directly utilisable in geodesy, making evident the quantities physically measurable The results obtained suggest that an agreement is possible between the geodesic measurements and the value of a certain constant furnished by the precession of the equinoxes

Leningrad

Academy of Sciences (*Comptes rendus*, No 19)—**E Selivanova** *Coelanthus subtilis* (Tratt) Seidel This grass, known hitherto from a few localities in western Europe, Siberia, and North America, has been found by the author near the river Volchov, in the Novgorod province of European Russia—**P Piatkov** Botanical and soil investigations on Novaya Zemlya, in the area of the polar geophysical observatory 'Matochkin Shar', during 1927–1928 A brief preliminary account of the investigations—**A N Labuntsov** The deposits of molybdenite in the Khibin tundra. A description of the deposits is presented

FRIDAY JANUARY 31

DIESEL ENGINE USERS ASSOCIATION (at Caxton Hall), at 3 30 —W S Burn High powered Oil Engines for Land Purposes

ROYAL ASTRONOMICAL SOCIETY (Geophysical Discussion) at 4 30 —Seismic Methods in Surveying Prof A O Rankine Dr H Jeffreys, Capt Shaw R S Whipple, F J W Whipple Chairman Prof H H Turner

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 —Prof W S Handley The Papilloma and its Menace

INSTITUTION OF ELECTRICAL ENGINEERS (London Students Section), at 6 15 —R R Poole Practical Television

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY (Chemical Section) at 7

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Graduate Section) (Joint Meeting) (at Newcastle upon Tyne), at 7 15 —W G Thompson The Electrical Propulsion of Ships

SOCIETY OF CHEMICAL INDUSTRY (Glasgow Section jointly with other Chemical Societies of Glasgow) (at 39 Elmbank Crescent, Glasgow), at 7 30 —Prof I M Heilbron Our Present Knowledge of the Fat soluble Vitamins A and D

JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting) at 7 30 —F Onions Superheating

ROYAL INSTITUTION OF GREAT BRITAIN, at 9 —Lord Rayleigh Iridescent Colour in Nature

INSTITUTION OF ELECTRICAL ENGINEERS (West Wales (Swansea) Sub Centre)

SATURDAY FEBRUARY 1

BRITISH MYCOLOGICAL SOCIETY (at University College) at 11 A M —D B Barnes Induced Variations in *Thamnidium elegans* —Prof W Brown Investigations on the Physico chemical Basis of Disease Resistance —Dr I Reichert Infection of *Fungi* with *Tilletia* —Dr G Samuel The Generic Names *Alternaria* and *Macrosporium*.—Dr H S Vasudeva The Effect of one Organism in Reducing the Virulence of Another

MATHEMATICAL ASSOCIATION (London Branch) (at Bedford College for Women) at 3 —Annual Meeting

ROYAL INSTITUTION OF GREAT BRITAIN, at 3 —Prof R W Chambers Sir Thomas More and his Friends (2).

ROYAL AERONAUTICAL SOCIETY (Yeovil Branch) (at Yeovil) —The Westland Wapiti in Service.

MONDAY, FEBRUARY 3

ROYAL SOCIETY, EDINBURGH at 4 30 —R W Wrigley On Changes of Rock Temperatures and Irregularities of the Earth's Rotation —S Williams The Morphology of *Tricuspidaria ophlebioides* Christ with Special Reference to the Aphlebioid Leaves —J S. Patel On the Existence of a Kyogenic Substance in the Corpus Luteum —Pius Koller Genetic Studies of the A and B Races of *Drosophila obscura* – Prof F A E Crew and Dr L Mirskaia Maturity in Albino and Coloured Mice —A. Mozley Report of the Jasper Park Lakes Investigations 1924-26 The Mollusca of Jasper Park

VICTORIA INSTITUTE (at Central Buildings Westminster) at 4 30.—Rev Dr W M Christie Jew and Arab in Palestine

ROYAL INSTITUTION OF GREAT BRITAIN at 5 —General Meeting

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 - Prof G Keynes The Radium Treatment of Carcinoma of the Breast.

SOCIETY OF ENGINEERS (at Geological Society) at 6 —W M Beckett Presidential Address

BRITISH PSYCHOLOGICAL SOCIETY (Education Section) (at London Day Training College), at 6 —Miss Evelyn Lawrence An Investigation into the Relation between Intelligence and Inheritance

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7 —H G S. Peck and others Discussion on Maintenance of Telephone Plant

UNIVERSITY OF BIRMINGHAM MEDICAL SOCIETY, at 8 —Prof J C Brash The Surgeon Anatomist and the History of Anatomy (William Haslam Oration)

ROYAL SOCIETY OF ARTS, at 8 —H J L Wright Three Master Etchers Rembrandt Meryon, Whistler (Cantor Lectures) (3).

SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Institution of Mechanical Engineers), at 8.—Dr H Levinstein Chemical Disarmament.

TWICKENHAM LITERARY AND SCIENTIFIC SOCIETY (at Free Library, Twickenham), at 8.—Capt. R. S. Gwatkin Williams: In the Hands of the Senussi.

INSTITUTION OF ELECTRICAL ENGINEERS (Western Centre) (at the Abbey Hall, Plymouth).—Capt. P. P. Eckersley: Broadcasting by Electric Waves (Faraday Lecture).

INSTITUTION OF THE RUBBER INDUSTRY (London and District Section) (at Engineers' Club, Coventry Street, W.1).—B. B. Evans: The Sun cracking of Vulcanised Rubber.

TUESDAY, FEBRUARY 4.

ELECTRICAL ASSOCIATION FOR WOMEN (at 15 Savoy Street, W.C.2), at 3.—G. S. Francis: Plastic Lighting and Modern Architecture.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Dr. F. W. Aston: Isotopes (3).

ROYAL SOCIETY OF MEDICINE (Orthopædics Section), at 5.30.—Clinical Meeting.

ZOOLOGICAL SOCIETY OF LONDON, at 5.30.—The Secretary: Report on the Additions to the Society's Menagerie during the months of November and December 1929.—E. Hollis: Exhibition of Skin of a Hen Pheasant showing Male Plumage.—J. Omer-Cooper: A Preliminary Investigation of the Fresh-water Fauna of Abyssinia.—Prof. S. J. Hickson: Report on the Hydras collected by Mr. J. Omer-Cooper in Abyssinia.—A. G. Lowndes: Freshwater Copepoda from Abyssinia collected by Mr. J. Omer-Cooper.—H. W. Parker: Report on the Amphibia collected by Mr. J. Omer-Cooper in Abyssinia.—Prof. S. J. Hickson: (*a*) On the Classification of the Alcyonaria. (*b*) Some Alcyonarians from the Western Pacific Ocean.—C. Ping: On the Cerebrum of *Felis t. gris*.—A. Loveridge: A List of the Amphibia of the British Territories in East Africa (Uganda, Kenya Colony, Tanganyika Territory, and Zanzibar), together with Keys for the Diagnosis of the Species.

SOCIETY OF CHEMICAL INDUSTRY (Yorkshire Section) (jointly with Hull Chemical and Engineering Society) (at Great Northern Station Hotel, Leeds), at 7.—Discussion on Fuel: Boiler Firing with Pulverised Fuel, H. Wheldon: Gaseous Fuel, B. Stonham: Boiler House Theory and the Medium Sized Works, G. H. Whyatt.

INSTITUTE OF METALS (Birmingham Section) (at Chamber of Commerce, Birmingham), at 7.—J. McNeil: Nickel Casting Alloys.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—W. A. Clark: A London Pilgrimage.

INSTITUTION OF ELECTRICAL ENGINEERS (Dundee Sub-Centre) (Informal Meeting) (at Lamb's Restaurant, Dundee), at 7.30.—Discussion on Curious Faults and Experiences.

INSTITUTION OF AUTOMOBILE ENGINEERS (at Royal Society of Arts), at 7.45.—Prof. B. P. Haigh: The Relative Safety of Mild and High-tensile Steel under Alternating and Pulsating Stresses.

TELEVISION SOCIETY (at Engineers' Club, Coventry Street, W.1), at 8.—G. P. Barnard: The Photoconductivity of Selenium and various other Substances.

INSTITUTION OF ELECTRICAL ENGINEERS (North Western Centre) (jointly with Institution of Post Office Electrical Engineers).—S. S. A. Watkins: Talking Films.

WEDNESDAY, FEBRUARY 5.

ROYAL SOCIETY OF MEDICINE (History of Medicine Section), at 5.—F. Prescott: Spallanzani on Spontaneous Generation and Digestion.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. J. H. Fisher: Some Points in Connexion with Perforating Injuries of the Eyeball.

GEOLOGICAL SOCIETY OF LONDON, at 5.30.—Prof. E. J. Garwood: The Tuedian Beds of Northern Cumberland and Roxburghshire east of the Liddelwater.—Sir Douglas Mawson: Pre-Ordovician Rocks of the McDonnell Ranges (Central Australia).

INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section) (at City and Guilds Engineering College), at 6.—Short Papers on New Developments.

GLASGOW UNIVERSITY ALCHEMISTS CLUB (at Glasgow University), at 7.30.—Prof. A. Hunter: The Nature and Action of Hormones.

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at Chemical Society), at 8.—R. L. Andrew: The Determination of Minute Amounts of Iodine in Soils and Waters.—Dr. D. W. Kent-Jones and A. J. Amos: Preliminary Studies in the Bacteriology of Wheat and Flour.—Dr. H. J. S. Sand: The Separation of Metals by Internal Electrolysis.—Ella M. Collin: The Rapid Determination of Bismuth and Copper in Lead Bullion by Internal Electrolysis.—G. W. Leeper: Notes on the Thiocyanate Method of Determining Iron: Influence of Different Classes of Phosphates.

ROYAL SOCIETY OF ARTS, at 8.—Sir William Clare Lees: Some Aspects of the Question of Trade with South America.

ENTOMOLOGICAL SOCIETY OF LONDON, at 8.

ROYAL SOCIETY OF MEDICINE (Surgery Section), at 8.30.—T. Edwards, W. H. C. Romanis, Dr. L. S. T. Burrell, and Dr. F. G. Chandler: Discussion on Intra-thoracic Tumours.

INSTITUTION OF ELECTRICAL ENGINEERS (Tees-Side Sub-Centre) (at Cleveland Technical Institute, Middlesbrough).

ROYAL MICROSCOPICAL SOCIETY (Biological Section).

THURSDAY, FEBRUARY 6.

ROYAL SOCIETY, at 4.30.—*Probably to be read*:—Prof. S. Chapman: A Note on the Measurement of the Specific Heats of Gases.—L. M. T. Gray and D. W. G. Style: The Absorption of Light by Chlorine, Bromine and their Gaseous Mixtures.—A. H. Davis and E. J. Evans: Measurement of Absorbing Power of Materials by the Stationary Wave Method.

LINNEAN SOCIETY, at 5.—Prof. R. R. Gates: Vegetation of the Mackenzie River Valley.—Dr. G. P. Bidder: The Importance of Cataclasma in Evolution.

LONDON MATHEMATICAL SOCIETY (at Royal Astronomical Society), at 5.—J. Hodgkinson: Conformal Representation by Means of Lamé Functions.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Dr. R. L. Smith-Rose: Radio Direction Finding by Transmission and Reception.

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 6.30.—J. W. Maccoll: Modern Research in Germany.

SOCIETY OF CHEMICAL INDUSTRY (Nottingham Section) (Annual Meeting) (at University College, Nottingham), at 7.10.—At 7.30.—C. F. Hammond: The Application of Submerged Combustion to the Dyeing, Laundry, Chemical and Allied Industries.

SOCIETY OF CHEMICAL INDUSTRY (Bristol Section) (at Bristol University), at 7.30.—J. D. Pratt: Rationalisation.

CHEMICAL SOCIETY, at 8.—Prof. A. J. Allmand and D. W. G. Style: The Photolysis of Aqueous Hydrogen Peroxide Solutions. Part I. Experimental Methods. Part II. Experimental Results.—Miss R. V. Henley and E. E. Turner: The Scission of Diaryl Ethers and Related Compounds by Means of Piperidine. Part III. The Nitration of 2:4-dibromo-2′:4′-dinitrodiphenyl Ether and of 2:4-dibromophenyl *p*-toluene-sulphonate and Benzoate. The Chlorination and Bromination of *m*-nitrophenol.

ROYAL AERONAUTICAL SOCIETY (Yeovil Branch) (at Yeovil).—D. B. Nivison: Aircraft Production Methods.

FRIDAY, FEBRUARY 7.

ROYAL SOCIETY OF ARTS (Indian Meeting), at 4.30.—G. H. Tipper: Recent Mineral Developments in India.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir John Rose Bradford: Massive Collapse of the Lung.

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute, Newcastle-upon-Tyne), at 6.—S. S. Cook: High Pressure Steam for Marine Work.

SOCIETY OF CHEMICAL INDUSTRY (Birmingham and Midland Section) (at Chamber of Commerce, Birmingham), at 6.30.—A. G. Lobley: Electric Furnaces for Heat Treatment.

SOCIETY OF CHEMICAL INDUSTRY (Manchester Section) (jointly with Institute of Fuel) (at Engineers' Club, Manchester), at 7.—Prof. M. W. Travers: The Fundamental Problems of Flue Gas Purification.

INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section), at 7.—G. F. Shotter: A New Null Method of Testing Instrument Transformers and its Applications.—R. J. S. Spilsbury and Dr. A. H. M. Arnold: Some Accessory Apparatus for Precise Measurements of Alternating Current.—Dr. A. H. M. Arnold: Precision Testing of Current Transformers.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group), at 7.—Practical Evening.

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Graduate Section) (at Bolbec Hall, Newcastle-upon-Tyne), at 7.15.—W. G. Thompson: The Electrical Propulsion of Ships.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—G. F. O'Riordan: Co-operation between Technical Institutions and Industry.

GEOLOGISTS' ASSOCIATION (Annual General Meeting) (at University College), at 7.30.—Presidential Address: The Geological Life Work of Sydney Savory Buckman.

PHILOLOGICAL SOCIETY (at University College), at 8.—Prof. V. G. Childe: Philology and Archæology.

ROYAL SOCIETY OF MEDICINE (Anæsthetics Section), at 8.30.—C. L. Hewer and I. W. Magill: Discussion on Anæsthesia in Thoracic Surgery.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Prof. L. Hill: Diving.

SATURDAY, FEBRUARY 8.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Rev. G. Cooke: Tonality and Form.

MINING INSTITUTE OF SCOTLAND (at Edinburgh).

PHYSIOLOGICAL SOCIETY (at St. Bartholomew's Hospital Medical College).

PUBLIC LECTURES.

SATURDAY, FEBRUARY 1.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—D. Martin Roberts: London in the Tudor Age.

TUESDAY, FEBRUARY 4.

GRESHAM COLLEGE, at 6.—Sir George Newman: Physic. (Succeeding Lectures on Feb. 5, 6, and 7.)

WEDNESDAY, FEBRUARY 5.

LONDON SCHOOL OF ECONOMICS, at 5.—R. J. Thompson: Economic Research in Agriculture—Its Bearing on the Supply of Food and Raw Materials.

UNIVERSITY COLLEGE, at 5.—Dr. R. J. Ludford: Cytology in Relation to Physiology and Pathology. (Succeeding Lectures on Feb. 12, 19, 26, Mar. 5 and 12.)

KING'S COLLEGE, at 5.30.—Prof. H. J. Rose: Methods of Research in Classical Mythology. (Succeeding Lectures on Feb. 6 and 7.)

AT 40 TORRINGTON SQUARE, at 5.30.—N. B. Jopson: The Early Civilisation and History of the Slave. (Succeeding Lecture on Feb. 12.)

BELFAST MUSEUM, at 8.—C. E. Kerr: Ulster Place Names.

THURSDAY, FEBRUARY 6.

KING'S COLLEGE, at 5.—C. J. Gadd: The Jews under the Persian Empire.

FRIDAY, FEBRUARY 7.

UNIVERSITY OF LEEDS, at 8.—Prof. Blanchard: Human Geography and the Methods of teaching Geography.

SATURDAY, FEBRUARY 8.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Miss M. A. Murray: Ancient Egyptian Jewellery.

CONFERENCE.

WEDNESDAY, FEBRUARY 5.

GRASSLAND CONFERENCE (at Harper Adams Agricultural College, Newport, Salop), at 2.—Dr. J. A. Hanley, W. B. Mercer, and R. Boutflour: Addresses on the Formation, Maintenance, and Utilisation of Temporary and Permanent Pastures.

Research and Finance in the Study of Man and his Past

IN a note which appeared in NATURE of Feb 1, p 175, the announcement of the departure of the British Museum's expedition to British Honduras for the purpose of continuing the excavation of Mayan antiquities is coupled with a reference to an appeal by the Director of the Museum for funds to carry on the work and to ensure its continuation It is held out as an inducement to subscribers, that the sites on which these investigations are being made are within imperial territory, and that this fact gives to British archæologists a security of tenure which they are unable to secure on any prehistoric site in the old world That this is an element in archæological research of no little importance is indicated by the recent removal of the operations of the British School of Archæology in Egypt to Palestine, as well as by the experience of those who have continued to work in Egypt since changed conditions have prevailed Even the intensely interesting archæological field which is opening up in India along the Indus Valley is not likely to offer rival attractions to Honduras in this respect, while at any rate investigation on important sites is primarily a function of the Archæological Survey The Schools of Archæology in Iraq and Palestine operate in mandated territory, while those at Athens and Rome are naturally entirely subject to the regulations for the time being of their hosts They may at any moment find their activities restricted, as happened in Greece a few years ago when the operations of foreign schools of archæology were limited to two sites in any one year The expedition to British Honduras, therefore, it is justly claimed, enjoys a unique advantage in that it is working entirely within the boundaries of British territory

We wish the Director's appeal every success, but while commending it strongly as in every way calling for the generous support of the public, it is in no spirit of criticism that we point out that it inevitably gives rise to a variety of reflections It may be said without undue partiality that British field work in archæology has proved itself second to none in scientific methods of excavation and in the accurate and painstaking recording and preservation of results Yet while our archæologists are to the fore in every field in the Old World, the New has been sadly neglected Students in Britain of the archæology and cultures of America—North, Central, and South—are a small, if distinguished, body. If, however, there is one man who played the

greatest part in establishing the modern study of Central American archæology, it is an Englishman, Dr A P Maudslay, whose remarkable journeys of exploration brought back from the Central American forests, surmounting almost incredible difficulties, a wonderful series of plaster casts of Mayan antiquities which were afterwards presented to the nation

The magnitude of this work has never been generally appreciated The density of vegetation in the tropical forest made it a work of intense endurance even to reach the ruins and to clear them from the vegetation with which they were covered , but apart from that, every ounce of the plaster of Paris used in making these large casts was imported from England and carried by the expedition to the sites on which it was used The total cost borne by Dr Maudslay himself was at least £10,000, while the labour and time involved by his expeditions will be appreciated when it is remembered that Capt Joyce's expedition to Pusilhá in 1929 with the aid of a motor tractor took eighteen days to cover a distance of 48 miles by land and river For Honduras that was good progress The whole way on land had to be cut through thick vegetation

With a record of this character behind us in Americanist studies—without reference to the valuable contribution made by Capt Joyce, both in his synthetic studies of American archæology and his original investigations—it seems incredible that the opportunity should be neglected The attention of British archæologists should be attracted to a study of such interest and importance A British school of American archæology should be built up to explore our own territory in Central America The fields of the Old World offer an attraction which cannot be denied They are beginning to link up the history of civilisation as a whole in time and space in a manner in which American archæology in its present isolation, apart from diffusionist views, cannot hope to do The development of scientific method on Old World sites makes them admirable training grounds for the student , but American archæology presents its own problems in method, and it must be remembered that even here stratigraphical problems have to be solved even if the conditions differ, as can be seen in the work of American archæologists in the South-Western States, in Mexico Valley, and in some of the other recent investigations in Central and South America

Further, in Central America it is difficult to forecast what the future may bring forth, for investigation has still to demonstrate with certainty the beginnings of this culture The opportunities for discovery seem to be practically unlimited The short trial aeroplane flight made from Belize recently by Col Lindbergh showed how many unknown ruins it was possible to sight in an area relatively restricted When once the facts of the case are appreciated, they require no emphasis to press the need for the formation of such a school, perhaps on the lines of Sir Flinders Petrie's Egyptian school rather than of those at Athens and Rome The British Museum's expedition, if placed on a permanent basis, might form its nucleus It would be a graceful recognition of a great piece of work, which is a credit to British archæological studies, if it could in some way be linked with the name of Dr Maudslay

These matters, however, lie with the future The British Museum's appeal is of the present The British Museum appeals for funds for an expedition of exploration in a British Colony ! In other words, a great national institution has to appeal to the generosity of the private individual to carry out work which its administration has decided is within its province and for which members of its own staff have been seconded In this year's expedition the experienced and exceptionally qualified leader is unable to participate, owing, it is presumed, to his official duties as Deputy Keeper , and part of the funds are derived from the generous gift of an American For this gift we are grateful, but an expedition so essentially British should be able to rely if necessary upon British money

The case of the Honduras Expedition is not singular The excavations at Ur, which have produced results epoch making in their revelation of the early history of civilisation, have also been carried out by an expedition of the British Museum , but although the Museum authorities were well aware of the importance of the site, they did not feel justified in entering upon the financial responsibilities involved by its excavation until a joint expedition was proposed by the Museum of the University of Pennsylvania Three seasons ago the excavation had to close down prematurely for lack of funds at a most important stage of its work, when the possibility of disturbance during the summer endangered the most momentous discoveries ever made on the site, as was shown immediately the work reopened in the following season

It scarcely calls for argument that work which is considered sufficiently important to be carried on under the ægis of a national institution such as the

British Museum should not depend for its continuity upon the precarious generosity of the private individual. Such investigations are not undertaken with undue frequency, or without careful consideration of their intrinsic importance and their moment in the general advancement of knowledge. If they are undertaken, it is surely beneath our dignity that the Director should be in such a position that he must appeal to the individual citizen, or even to a foreign benefactor, to provide the funds to carry out what it has been decided after due consideration is a proper function of a national institution.

The Royal Commission on Museums and National Galleries has reported with admirable moderation and discretion; but it has shown that our national collections have been starved. The Report recognises the nation's indebtedness to the private benefactor in the past; it hopes that we may still rely upon the generosity of the individual in the future. Archæological exploration, however, is too often a matter of immediate opportunity, both in site and personnel, to depend upon fortuitous finance. It would be an excellent thing if a commission similar to that on the Museums were appointed to examine the question of State assistance to scientific research in general. Some provision is already made out of national funds for certain branches of research; but the benefits of this provision are practically confined to the physical sciences.

How much is done for the humanistic sciences? What funds are available for anthropology? A line has been drawn at physical anthropology, while the amounts available for archæology from the grants allocated by the Royal Society are, as a rule and relatively, almost negligible. It has been pointed out again and again that, through a lack of funds, enthnographic material within the Empire is being allowed to disappear rapidly as our primitive peoples come into contact with European culture. Archæological material is perhaps in better case; but if so, this is due to private benefaction and a greater interest taken in the subject by the public, who are sometimes prepared to give practical expression to that interest in the form of a subscription. Even so, financial resources are precarious and often inadequate.

The success of the appeal for a School of Archæology in Iraq was almost entirely a success of the personality of the late Miss Gertrude Bell. The appeal of the British School of Archæology in Palestine failed utterly, and that too at a time when the Government had withdrawn its temporary financial support. Here, however, if anywhere, might archæology have looked for sympathy and assistance from the public when it was engaged in investigating the early history of that country in which so many of our religious and intellectual antecedents are rooted. Palestine is the chief spiritual fount of the British peoples, but it is not the only one. We have British schools in other countries to which our civilisation is almost as deeply indebted. The schools at Athens and Rome have been generously supported by subscription and benefaction, but their means have been and continue to be inadequate to carry out fully the programme of instruction and research they have set themselves. Further, in each case they represent the British nation in almost an equal degree with the British Embassy. They provide an intellectual and academic, as well as a social, centre representative of the British nation, for visitors and residents alike. That their work should be endangered or restricted for lack of funds does us as a nation no credit.

The question of the subvention of research in humanistic studies from public funds opens up a wide field upon which it is not possible here to do more than touch. The archæology of Great Britain itself, for example, has its no less urgent needs. While claims on the public purse are many and the country is overburdened with taxation, a plea from any one department of knowledge may easily be set aside as inopportune on grounds of public policy. It is for this reason that for a reasoned verdict on the urgency of the plea we should look to a public inquiry into the present needs of research, especially in the humanistic sciences.

Mendelism and Anthropology

Heredity in Man. By Prof. R. Ruggles Gates. Pp. xiii + 385. (London: Constable and Co., Ltd., 1929.) 24*s.* net.

A BOOK with a title "Heredity in Man" will attract the attention of the many who are interested in human affairs, and who have been made aware of the proven usefulness of the contributions of the science of genetics to the practices of animal and plant breeding.

It will appeal strongly to such as hold the view that the further evolution of man, and therefore of society, will take the form of the conscious and deliberate manipulation by man of the attributes of his environment and of the mechanisms that are himself. These will agree with the statement in the preface that a knowledge of human heredity

must form the basis of any enlightened attempt to influence the future development of the human race This is the point of view of the ardent eugenist, who would seem to advocate the application of stock breeding practices for the prevention of the continued existence of undesired types

The book will be read by the student of political science as well as by those politicians, professional and amateur, who, nowadays, so eagerly seek biological endorsement for their own peculiar prejudices To day it is not uncommon, when the politician speaks, to hear the views of some biologist If, for example, in a country, changing economic and political circumstances make it desirable on the part of those presently in power to limit the numbers of immigrants from countries where a lower standard of living and different habits and manners obtain, the official reason that is commonly given in explanation of such an attitude and for such a policy is one that is based on the teachings of those biologists who preach the view that certain races or racial types are genetically superior

Reading this book, the eugenist who seeks encouragement for policies of a positive kind, and the politician who seeks an authority that he may quote, will be disappointed, for Prof Ruggles Gates avoids discussion of the implications of genetic fact, contenting himself with the presentation of what has been said and what has been thought, and leaving the task of weaving these facts into considered policies to other people, probably less able than himself

The book will be read by the physician who seeks an answer to the question now frequently put to him, 'Should we two with such and-such family histories, or with such and such personal disabilities, marry and have children ?' It is true that now the domination of bacteriology in medicine is waning, medical practitioners are studying much more thoroughly the rôle of inheritance in the etiology of disease, and that this new and intensified interest is revealed in the quality of their writings But though the doctor will find in this book a very complete compilation of what has been recorded and of what has been said of the mode of inheritance of physical defect and derangement, he will probably decide that the author too frequently goes beyond the human subject for his examples—there are at least a hundred references to inherited characters in animals other than man—and he will certainly find that in a very great many instances of such inherited abnormality he can obtain nothing that will help him to answer categorically the question that is asked. This, unfortunately, must necessarily be so, for the majority of the records of family histories have been taken by such as have been untrained in genetical methods and relate all too commonly to individuals introduced solely through anecdote But even though Prof Ruggles Gates advises but rarely, as when, for example, he states, quoting Macklin, "13 per cent of pupils in blind schools are blind through cataract They should obviously not have children ", such facts as are known are fairly given, and these will permit the physician himself, having read the book, to present a reasonable opinion

It is accepted that, socially, the inherited physical defects and derangements are not so important as are the mental The reason for this would seem to be that a greater proportion of the physical are either curable or are of a kind that do not seriously handicap their exhibitors in competition with their fellows The fact that polydactyly is inherited is of interest and of scientific importance, but no one would advocate legislation which would deny parentage to the polydactylous The condition does not seriously handicap its exhibitor, and, in any case, the extra digit in each succeeding generation can be cut off Red green blindness is an inherited character, and unless parentage is denied to such as carry in their hereditary constitutions the factors responsible, it will spread slowly but surely through a population But although it cannot be cured, it is not, in present circumstances, a serious handicap It can therefore be disregarded It is only when a defect is incurable and when it renders its exhibitor unable successfully to compete with his fellows that it constitutes a problem The simplest method of solving this would of course be to find a cure, and doubtless, as time passes, advances in medical science will give to mankind the power to repair hereditary deficiencies and to prevent many forms of genetic defect

Since most of the inherited and undesirable mental characters are presently incurable, since we do not know the chemistry of normality, and because they render the individual a burden to himself and, more particularly, to his fellows, they constitute a very serious social problem For example, Prof Ruggles Gates quotes Goddard, who states that 50 per cent of all paupers and of all prostitutes are feeble minded, and accepts the statement that feeble mindedness is, in the majority of instances, an inherited character, behaving as a simple Mendelian recessive Here again Prof

Ruggles Gates studiously avoids any discussion of the implications of this statement Surely, if it is accepted that feeble-mindedness is commonly a hereditary character, behaving in inheritance as a simple recessive, the methods to be adopted to prevent the multiplication of such stocks are obvious Surely it is reasonable that those who read a book such as this should expect therein a statement of the views of the author concerning such a matter as this Possibly, Prof Ruggles Gates is of the opinion that it is the task of the biologist to present the facts, and not for the biologist alone to discuss policies based on these facts Many will agree with this view But the biologist to day cannot refuse to make his contribution toward the construction of policies that affect mankind It is probable that Prof Ruggles Gates holds the view that before the biologist can advise action he must be in possession of all the pertinent data The fact that only some 30 pages out of a total of some 380 are devoted to a discussion of mental characters in man will show how very little is known of those normal and abnormal characters which are so important socially

It is only as one approaches the end of the book that one realises that Prof Ruggles Gates's interest in human heredity is directly related to his activities as an anthropologist Throughout the book he neglects the interest of the politician, the physician, and the eugenist, though he continually refers to matters of profound interest to them, and for the reason that undoubtedly he is addressing himself to the anthropologist He treats the subject of racial crossing mainly from this angle, and discusses all too briefly the general policy of such intermixtures From the very insufficient and haphazard crosses that have been made he concludes—as would be expected from one with genetical knowledge—that the melting pot conception is now discredited, and that segregation of independently inherited characters occurs even after thousands of years

It is entirely satisfactory to know that through such a book as this the genetic point of view will be introduced into anthropological literature, and there is no doubt that in writing this book Prof Ruggles Gates has rendered great service But anthropologists are few, and politicians, physicians, and eugenists are many, and it is to be hoped that Prof Ruggles Gates will now address the large audience that awaits him. The geneticist has contributions of the utmost importance to make, and it is highly desirable that we should know what Prof Ruggles Gates, as a geneticist, has to say upon such questions as, for example, the effect of emigration and immigration upon the Scottish stock, the worthiness of our present information concerning feeble mindedness, the validity of the argument concerning racial genetic superiority There are scores of questions such as these that are puzzling the minds of those who are guiding the destinies of Great Britain, and they can only be answered when the biologist has made his contribution

Having read the book carefully, one suffers from a feeling of regret that the author has quoted the opinions of others so much and presented his own so infrequently, for, without doubt, Prof Ruggles Gates can bring to the discussion of this subject of human heredity, fresh points of view that would be exceedingly stimulating F A E CREW

Science and Art of Lubrication

The Principles and Practice of Lubrication a Manual for Petroleum Technologists, Students, Engineers, Oil Salesmen, etc By Prof Alfred W Nash and Dr A R Bowen Pp xi + 315 + 29 plates (London Chapman and Hall, Ltd, 1929) *15s* net

IN the opinion of the authors, lubrication is no longer an art, for to secure efficiency it is now necessary to understand the scientific principles upon which the proper choice of lubricating oils and greases depends, and also the laws upon which the proper design of bearings is based Engineers in the past have had to rely wholly upon their practical experience when dealing with lubrication problems, but of recent years scientifically conducted experiments have shown what the actual conditions are under which lubricated bearings run One of the most satisfactory features of such research work has been that whilst engineers interested in lubrication problems are more inclined to study the teachings of scientific discovery, scientific workers are more desirous of assisting the practical man to ascertain the causes of the difficulties met with in practice, with the result that it is now possible to produce a manual, such as the one we are considering, dealing with the subject rather as a science than as an art However, it must not be forgotten that, although much has been accomplished, there remain some peculiar frictional phenomena which cannot be satisfactorily accounted for

The practice of lubrication is essentially the interposition between two surfaces in rubbing contact, of some fluid or soft solid, which will sufficiently reduce the frictional resistance to prevent

them from heating and injuring each other The various types of friction are treated of in Chap ii, and are classified under two headings as follows

UNLUBRICATED SURFACES

(a) *Dry Friction*—This represents friction between perfectly clean, dry, solid surfaces

(b) *Rolling Friction*—A term applied to such reactionary force as is found between solid surfaces separated by balls or rollers

LUBRICATED SURFACES

(c) *Boundary Friction*

(d) *Fluid Friction*

In the case of fluid friction the surfaces are entirely separated from each other by a comparatively thick film of the lubricant Beauchamp Towers' experiments on journal friction are clearly described, as also are the investigations of Osborne Reynolds concerning the cause of the separation of the shaft and bearing surfaces by a film of oil under pressure When the rubbing surfaces are flat they separate only slightly, and a comparatively thick fluid film does not form Michell's method of causing such a thick lubricating film to accumulate is figured and described The coefficient of friction of bearings resting upon such viscous films is very small, so small indeed that the heat developed by friction escapes freely by conduction and convection, and there is no undue rise of temperature The authors, however, point out that, as evidenced by wear, very few bearings in practice can be working at all times under conditions of complete fluid friction, as there is no wear when such conditions prevail On this account all bearings, even when they have been designed so that they are in most conditions of running separated by a lubricating viscous film, must be supplied with an oil which has a low coefficient of static friction, so as to keep them cool when boundary conditions of friction supervene

Boundary friction receives a good deal of attention from the authors, the experimental work of Sir William Hardy and others being cited When viscous liquids or greases are spread over surfaces in rubbing contact, the resulting threshold or static friction is not found to bear any regular relationship to the viscosity of the lubricant, except when members of chemical series, such as the paraffins or alcohols, are contrasted the one with the other Engineers have always recognised this, and have regarded as lubricants only those liquids with small threshold frictions Thus, quite apart from its viscosity, a liquid, to be a good lubricant, must possess marked 'oiliness' Clean solids in rubbing contact also have widely different threshold frictions, that is, they vary in 'unctuousness' In practice the lowest frictions are obtained by using solids for the rubbing surfaces which have marked unctuousness, with lubricants of marked oiliness

Specific gravity and viscosity are dealt with in Chap iii, methods for their determination being described, and apparatus illustrated

In Chap iv the design and lubrication of bearings are discussed As both animal and vegetable lubricants possess the property of oiliness much more markedly than mineral oils, the authors consider that the importance of the property of unctuousness in bearing metals cannot be overestimated, a good bearing metal often enabling a moderately oily lubricant to work satisfactorily Indeed, this chapter is sure to prove useful to the engineer

Chap v deals with the source, methods of manufacture, preparation, and composition of lubricants, as well as their compounding and blending In the following two chapters the chemistry and the chemical and physical testing of lubricants are considered Here (p 191) the authors rightly remark "It has already been pointed out that the best judgment of the value of an oil is made from a test in the machinery for which it is intended, such a test can constitute the only reliable guide to the durability and lubricating value of the oil However, there are certain chemical tests which should be made before the oil reaches the engineer, and these tests, although not deciding the lubricating power, give important information upon the degree of refining of the oil, its mineral, fatty, or compound nature, and also the impurities or adulterants"

The mechanical testing of lubricants in special machines is considered in Chap ix Mechanical friction tests being the only fair means of ascertaining the lubricating value of oils, they are most satisfactorily made by using one or other of the many forms of mechanical oil testing machines which have been devised to reproduce as closely as possible the conditions met with under various practical conditions of work Thus we have here described machines for determining unctuousness and oiliness, and others for conditions when these and viscous film conditions are combined

The manual has been well produced, the type being clear, and the illustrations numerous and good

R M D

Modern Light

Müller-Pouillets Lehrbuch der Physik Elfte Auflage Herausgegeben von A Eucken, O Lummer und E Waetzmann In funf Banden Band 2 *Lehre von der strahlenden Energie (Optik)* Herausgegeben von Karl Wilhelm Meissner Zweite Halfte, Erster Teil Pp xvi + 929 1708 + 19 Zweite Halfte, Zweiter Teil Pp xv + 1709 2392 (Braunschweig Friedr Vieweg und Sohn A -G , 1929) 87 50 gold marks

THESE important contributions to the literature on optics have been produced under very adverse conditions The initial responsibility for their production was assumed by O Lummer, who arranged the division of the work and its distribution among various contributors Unfortunately, Lummer died in July 1925, when the work was in an advanced stage and the first half volume of "Die Lehre von der strahlenden Energie" was already in the press The first half volume, therefore, appeared in 1926, and the two books which form the second half-volume are now before us The long interval of time between the appearance of the first and second half volumes is due partly to the withdrawal of many of Lummer's associates from active participation in the work, and partly to the need for considerable revision and enlargement of the articles which were ready for the press at the time of Lummer's death, in order to bring them up to date

In spite of these serious difficulties, the new editor, K W Meissner, has produced two books which will be regarded by all teachers of physics as extremely valuable contributions, although it must be recorded that their contents are overwhelmingly drawn from German sources As Lummer's original plan of production had more or less to be maintained, there is some slight overlapping, but only one or two important points have been omitted from the work The books are profusely illustrated, and many of the illustrations have great pedagogical value

Meissner commences the new half volume with a short section on plane polarised light, which is followed by sections on double refraction, rotation of the plane of polarisation, and the crystal optics of X rays, by E Buchwald The mathematical treatment of the Fresnel wave theory is rather condensed, but we appreciate the clear explanation of the way in which a modern polarimeter should be used On photometry the English reader has excellent sources of information in his own tongue, but the article contributed by H Kohn is not without distinction His discussion of Lambert's law is particularly good, as also are his descriptions of modern spectro photometers and colorimeters, we wish, however, that he did not consider it necessary to express the pentane lamp as 10/9 Hefner unit The apparatus and technique for the investigation of the whole spectrum are described in a series of articles by Czerny, Gehrcke, Hettner, and Meissner The methods described for producing spectra include the explosion of wires and King's carbon furnace Czerny and Hettner are also responsible for an excellent article on black body radiation, although the experimental portions do not take into account work carried out later than 1926, and no modern American experiments are described The theoretical portions have, however, been brought up to date by W Pauli, who, incidentally, emphasises that the Compton effect provides a proof that the pressure of radiation is discontinuous R Minkowski completes the first book with a long chapter on the theory of reflection, refraction, and dispersion, in which adequate attention is paid to modern developments

The second book opens with an introductory chapter on the fundamental ideas of the quantum theory applied to atomic structure Although this introduction is very good, it would not excite enthusiasm were it not for the fact that to it are added sections on the magnetic properties of electrons and on the new wave mechanics These additions increase the value of the chapter enormously, although it is felt that more attention could well have been paid to the experimental aspects, and, for example, some mention made of G P Thomson's work The reader will have little difficulty in following the excellent summary of Heisenberg's theory of the helium spectrum, which led directly to the prediction of the two forms of hydrogen

A short description of the production of spectral lines by G Hertz is the prelude to lengthy contributions by F Paschen and A Kratzer, who respectively describe in detail the structure and origin of line and band spectra The investigation and theory of the Zeeman effect are very ably summarised by E Back, whose work with intense magnetic fields is so well known D Coster is responsible for the treatment of X-ray spectroscopy He gives a historical outline of its development, and then describes in detail the design of modern X ray tubes and spectrographs for research purposes He discusses the bearing of Bohr and Stoner's ideas on the experimental results and devotes considerable attention to the continuous X-ray spectrum and to the phenomena of dispersion

Of all the German workers on radioactivity, few can be better qualified to write on X-rays than Fräulein Lise Meitner Her contribution is brief and to the point, but would be improved by the provision of more diagrams The contributions of R Ladenburg on magneto- and electro-optics are very impressive R W Pohl deals with photoelectricity, but his treatment of the main phenomena is rather of the nature of a summary This is mainly because he confines himself to the purely optical aspects of photoelectricity We would certainly have expected some reference to the work of Auger in the section on the photoelectric effect in gases, for there exists at least one excellent summary of this work in German B Gudden is responsible for the articles on fluorescence and phosphorescence They cover a wide field, but the average English reader will be surprised at the smallness of the space devoted to the effect of collisions of the second kind on the fluorescence of gases He will also be surprised at the frequent omission of names from the index to the half volume, but this will only slightly diminish his respect for an excellent work

International Astronomical Union

International Research Council International Astronomical Union (Union Astronomique Internationale) Transactions of the International Astronomical Union Vol 3 *Third General Assembly held at Leiden, July 5 to July 13, 1928* Edited by F J M Stratton Pp ix + 348 (Cambridge At the University Press, 1929) 15*s* net

THE third volume of the *Transactions* of the International Astronomical Union, embodying an account of the proceedings at the third general assembly held at Leyden in July 1929, is a valuable document which, in its general form, closely resembles the previous volumes It opens with the reports of the executive committee and the various commissions of which the Union consists, which were circulated to members before the meeting and formed the basis of discussion The modifications and decisions which were made at Leyden have, however, been included so far as possible without incurring heavy expenditure on printing, so that this part of the *Transactions* differs to some extent from the reports issued before the meeting

The volume under notice forms, in fact, a fairly complete statement of the present position of the programmes of research in the various departments of astronomy For actual completeness, however, Part 3 also must be consulted, which gives an account of the meetings of each commission at Leyden, with the recommendations adopted Part 2 deals with the inaugural ceremony and opening general assembly, and Part 4 with the closing general assembly Most of the material in the first four sections is given in English In Part 5 the several resolutions adopted by the Union are collected in a classified form and given in French A number of appendices record the statutes of the International Research Council and the International Astronomical Union, the names of members of the committees and commissions, and other cognate information

It is much to be hoped that the efforts of the Union to standardise the procedure of astronomers in certain matters hitherto left to individual choice will meet with the success they deserve Such matters as the definition of the galactic system of co ordinates, the form adopted in publishing astronomical papers, and the abbreviations by which recognised publications, societies, etc , are represented, have been given serious and praiseworthy attention by the respective commissions, and their recommendations, if generally adopted, would greatly facilitate the work of astronomers In particular we would mention the recommendation, already adopted by some editors, that every astronomical paper should be accompanied by a short summary The Union has, of course, no power to enforce its desires on these points, and this is an additional reason why attention should be specially directed to them

To those who were fortunate enough to attend the Leyden meeting, this volume will come as a welcome reminder of a delightful experience, and to astronomers everywhere it will be an indispensable guide Prof Stratton is to be congratulated on well maintaining the high standard set by previous volumes

Our Bookshelf.

Practical Design of Simple Steel Structures By David S Stewart (The Glasgow Text-Books, edited by G Moncur) Vol 1 *Shop Practice, Riveted Connections and Beams, etc* Pp xv + 183 12*s* Vol 2 *Plate Girders, Columns, Trusses, etc* Pp xv + 215 16*s* (London . Constable and Co , Ltd , 1929)

TEXT-BOOKS on structural engineering are now so numerous that justification for a new one must really be difficult to find The field is certainly amply covered by many excellent treatises, the names of which will at once suggest themselves to the student and the practitioner In the majority

of these publications, however, theoretical considerations are paramount, sometimes to the exclusion of all others Guided by their instruction, the student would be fully equipped to design structures on correct scientific principles But, in actual practice, there are divergences from theoretical considerations on various grounds, and this aspect of the subject is generally but slightly touched upon In the case of the present volumes, such a defect does not exist, and they are to be welcomed as a most valuable vade mecum to the inexperienced and the beginner They are full of practical hints and directions of sound economical value, such as (to mention only a few) the limitations in the rolling of steel plates and sections, and the extras chargeable on excess sizes, the deterrent effect of meticulous drawings and specifications on the obtainment of reasonable quotations, the loss due to scrap material, etc Some of the hints appear to affect minor details, but the cumulative effect is considerable Perusal of the work, with its clear appreciation of the practical aspect of structural design, was a distinct pleasure

In a short notice it is only possible to deal very briefly with the contents of the volumes, but a summarised statement is as follows Vol 1 consists of eleven chapters dealing with rolled sections for structural purposes , drawing office , template loft and the works , fastenings, pitches, and simple riveted joints of plates , flange plate splices , splices for angles, joists, and channels , splices for the web plates of plate girders , eccentric riveted connexions , wind pressure—factors of safety , beams and the design of a joist and channel crane gantry girder Vol 2 has nine chapters dealing with plate girders , design of a 40-ft span gantry girder , axially loaded columns and their foundations , non axially loaded columns , design of a 55 ft span roof truss , roof trusses , portal trusses and workshops , design of a lattice girder footbridge , and design of a 70-ft span through railway bridge Full details of the designs are given and many examples are worked out in detail, both in symbols and numerically Altogether, excellent volumes and cordially to be recommended

B C

An Introduction to the Study of Map Projections By J A Steers Second and revised edition Pp xxiii + 204 (London University of London Press, Ltd , 1929) 8*s* 6*d* net

THIS little book is, in the main, what it professes to be, and is written chiefly for those students of geography who have but little knowledge of mathematics For that reason the study is cast largely in an elementary geometrical form, and mathematical symbols are, where possible, avoided The plan of the book includes chapters on the properties of projections, their systems, the measurement of areas, the use of scales, and then a description and explanation of the more common projections, especially those to be found in atlases, and those of practical use in topography Given the limitations imposed on himself by the author, the book fulfils its purpose, and its appeal to the non mathematical student is evidenced by the fact that this second edition has been called for three years after the issue of the first

A few matters might perhaps be considered by the author before the preparation of a third edition The use of the word ' normal ' instead of the usual term ' polar ', for that particular case of zenithal projections, seems to be an unnecessary alteration in established practice The statement on p 170 that the 6 inch maps of the Ordnance Survey are plotted by rectangular co ordinates from a central meridian, might give the impression that there is one such meridian, whereas these maps are plotted by counties or groups of counties At the beginning of the book appears a classification in which all projections which are not zenithal, conical, or cylindrical are boldly dumped together as conventional—a possible arrangement, but not commonly accepted Finally, it may be as well to sound a note of warning against the habit of looking at map projections from a purely geometrical point of view No thoroughly sound understanding of the beautiful subject of map projections can be arrived at through geometrical constructions

A History of the Birds of Essex By William E Glegg Pp xxxv + 342 + 20 plates (London H F and G Witherby, 1929) 25*s* net

THIRTY-NINE years ago Mr Miller Christy's well-known work on ' The Birds of Essex " was published, and advances in the technique of identification as well as some changes in the status of the birds themselves have taken place during the intervening years This new volume, which takes account of the changes and deals critically with the older as well as with new records, must therefore supplant in most respects the earlier work as the text book of Essex ornithologists The avifauna of the county is now known to comprise 281 forms, of which 95 are breeding birds, 26 are regular winter visitors (although it will be noted that in each of these figures there is a discrepancy between the statements on pp xxiv and xxxiv), and 160 are birds of passage or irregular visitors

In connexion with each species are given the records of local occurrences and distribution, migration movements and their dates The book contains just the information that the local naturalist demands, and the introduction, which with advantage might have been very considerably extended, places parochial details in a more general setting

Chemistry of Pulp and Paper Making By Edwin Sutermeister Second edition, rewritten Pp x + 565 (New York John Wiley and Sons, Inc , London Chapman and Hall, Ltd , 1929) 32*s* 6*d* net

THE new edition of this valuable work, which first appeared in 1920, has been carefully revised and brought up to-date In incorporating the fresh material, the author has continued his useful practice of giving the original sources of his information in footnotes The work is admirably printed and illustrated, and it will be welcomed by an increasing number of chemical workers in the pulp and paper industry

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

The 'Wave-band' Theory of Wireless Transmission

THE article on this subject in NATURE of Jan 18 by Sir Ambrose Fleming is scarcely a complete statement of the usually accepted 'wave band' theory, and unless the more complete aspects of this theory and their significance with respect to the number of wireless telephone stations that can operate on a given range of wave length, and with regard to the possibilities of the extensive use of television, are correctly stated, it is to be feared that misconceptions will arise

The so called 'side bands' are more than a mere mathematical conception Their existence admits of the simple experimental demonstration of taking a resonance curve of a selective receiver with an unmodulated, and then with a modulated, valve oscillator In the latter case resonant 'humps' can be shown to exist at the frequencies $(p \pm q)/2\pi$, $(p \pm 2q)/2\pi$, etc The same experiment shows that a selective receiver responds to a modulated electromotive force quite differently from an unselective receiver, and it is here perhaps that the real explanation is to be found of the width of frequency band found necessary in practice If a sudden change of amplitude takes place an undamped receiver will continue to oscillate for many cycles before its amplitude falls correspondingly Its response to sudden changes is therefore not strictly in accordance with the changes of the received impulse and the rendering is imperfect The well known effect of excessive reaction in a broadcast receiver is due to this cause A heavily damped oscillator, however, follows quickly the changes of amplitude and gives a true rendering But such a heavily damped oscillator cannot be limited to picking up energy from a narrow band of frequency Or, as the wave band theorists express it, the sudden changes involve a certain 'width of band'

Thus, whether the side bands exist or not is merely a matter of a choice of points of view The final results are the same, namely, that a considerable range of frequency is necessary for each line of communication, and the higher the frequency of the changes, the wider the range of frequency on which energy must be received by the receiver Hence, since television involves the greatest rapidity of change of amplitude, it also necessarily involves the most highly damped receiver and thus the widest band of frequency

CECIL L FORTESCUE
City and Guilds (Engineering) College,
Exhibition Road,
London, S W 7, Jan 21

IN NATURE of Jan 18, Sir Ambrose Fleming presents the wave band theory of wireless transmission as a mathematical fiction and issues a caution against being misled by the assumption of any physical reality in the so called 'side waves' It can be shown, however, not only that this assumption is perfectly justifiable, but also that the other mode of thought is liable to lead to false conclusions

Adopting Sir Ambrose Fleming's notation, we may write for the modulated part of a high frequency signal

$$a = A \cos qt \sin pt,$$

in which $q/2\pi$ is the audio frequency and $p/2\pi$ is the radio frequency This is mathematically indistinguishable from

$$\tfrac{1}{2}A(\sin \overline{p+q}t + \sin \overline{p-q}t),$$

and the question arises whether there is *any* sort of distinction The same kind of question arises when we attempt to distinguish a force from the vector sum of its components, and either question is one of philosophy which need not concern us here

The inference which one is invited to draw from Sir Ambrose Fleming's article is that if a signal $\Sigma A \cos qt \sin pt$ were applied to a band pass filter with a pass range of $p - q_0$ to $p + q_0$ it would emerge intact, but everybody knows that in fact all the terms corresponding to $q>q_0$ are cut down

The possibility of filtering out side waves, and of 'single side band' transmission and the like, are the usual arguments for their physical existence, but the root of the matter and the relation between the two points of view can be more clearly exhibited thus

The solution of any electrical network problem turns on the solution of simultaneous or possibly partial linear differential equations which may be typefied by a simple case

$$\ddot{y} + B\dot{y} + Cy = f(t)$$

Here y is the current in a certain branch and $f(t)$ is the 'driving force', which may, for example, be $A \cos qt \sin pt$ In this form there is no generally known method of solution, but if the right hand side is replaced by $\tfrac{1}{2}A$ ($\sin \overline{p-q}t + \sin \overline{p+q}t$), the equation assumes a well known standard form and the solution is equally a solution of the original, because there is no mathematical distinction between the two forms of the right hand side

Occasionally it is possible to recombine the $\overline{p-q}t$ and $\overline{p+q}t$ terms occurring in the solution, in this event one might regard the introduction of the side wave terms as a mathematical fiction, but far more generally no such recombination is possible, and this is the basis of the 'real side wave' viewpoint

Even so it may be possible to develop a calculus of the subject which does not employ the side wave concept, but it is difficult to see how it could fail to be cumbersome, and certainly less convenient than the known methods But if it is proposed to think on such lines, an amendment does seem necessary to Sir Ambrose Fleming's statement, "The whole question at issue then is, What range of amplitude is admissible?" The question surely is not how *much* the amplitude may vary, but at what frequency

LESLIE H BEDFORD

IT is evident there are strong differences of opinion as to the validity of the accepted 'wave band' theory Prof Fortescue and Mr Bedford have stated with great clearness their views May I present the following considerations on the opposite side?

If a highly selective wireless receiver associated with a good moving coil loud speaker is used to receive vocal or instrumental music from a broadcast station, we do not find that we have any imperfect reproduction of high notes relatively to bass notes in receiving music broadcast If we are in tune for very low frequency acoustic modulation or bass notes, we are also in tune for high frequency or shrill notes If this was not the case, we should have to keep on adjusting our receiver as the pitch of the music varied

Now musical pitch varies from 40 to 4000, and if the carrier wave has a frequency, say, of 193 kc/s (long wave Daventry), then the ordinary theory would assert that for each of the highest notes of the orchestra there are two simultaneous carrier waves emitted which may differ in frequency by as much as 4 per cent

A good selective receiver cannot respond equally well to waves differing so much in frequency If, then, these two component waves really exist, we should have to set our receiver condenser so as to pick them up in equal strength, without which the modulation would not be created If the receiver resonance curve is sharp, this implies that on the band theory high notes in music would not be reproduced sufficiently loud relatively to low notes Hence one would be led to the conclusion that the best results would be obtained by the use of a not very selective receiver But that is contrary to experience Makers of wireless receivers endeavour to give them the highest selectivity - not only to get the best results on one broadcast station but also to exclude that back ground of noise which is due to the jam of waves in the ether at present of closely adjacent frequencies

What we require to improve broadcasting is greater constancy in emitted carrier wave length and greater selectivity in all receivers

If it were merely a question of formulating explana tions, everyone is entitled to regard the results in whatever light he pleases or to employ what mathe matical artifices enables him to solve equations But when we come to practice and official regulations, it is a great disadvantage from the point of view of experimental progress to have these official regulations such as the 9 kilocycle wide wave band, based upon a merely theoretical interpretation of certain facts, and moreover an interpretation which seems out of agreement with practical experience

Light in Four Dimensional Space

IN works on relativity little mention is made of the plane in which light travels in four dimensional space If we assume that a small body sends out rays of light in a three dimensional plane at right angles to its world line, the form of the equation for the interval ds

$$ds^2 = c^2dt^2 - dx^2 - dy^2 - dz^2 \qquad (1)$$

can be simply explained without the use of imaginary angles and imaginary time

Let the plane of Fig 1 be a section of four dimen sional Euclidean space containing the world lines of the following particles or observers AA, BB, and CC at rest relative to each other, and DD in motion relative to the other three The sinuous lines re present the bobs of the pendulums of two clocks travelling with A and D *Time* in the case of each observer has of course the direction of his own world line At P and Q rays of light are sent out from DD They travel at right angles to DD in three dimensional planes, which cut the plane of the diagram in the lines XX and YY An observer AA wishing to measure the interval PQ will make the two measurements, dx with a foot rule and dt with his clock. He will then calculate the interval by the formula

$$ds^2 = \tfrac{1}{2}c^2dt^2\left\{1 + \sqrt{1 - 4\left(\frac{dx}{cdt}\right)^2}\right\} \qquad (2)$$

which follows immediately from the geometry of the figure, for $dx/\sin\theta = ds = cdt\cos\theta$

where $ds^2 = c^2dt^2\cos^2\theta = \tfrac{1}{2}c^2dt^2\{1+\cos 2\theta\}$

$$= \tfrac{1}{2}c^2dt^2\left\{1 + \sqrt{1 - 4\left(\frac{dx}{cdt}\right)^2}\right\}$$

In this form ds is invariant to all observers If we write $v = dx/cdt$ and neglect high powers of v, formula (2) becomes

$$ds^2 = c^2dt^2(1 - v^4 - \qquad) - dx^2 \qquad (3)$$

which reduces to formula (1) when the relative velocity is neglected altogether

Observer AA is very much handicapped in his choice of co ordinates A fictitious observer at right angles to him, or to the plane of the diagram, for example, could measure the co ordinate dp with a foot rule, which would give the simple formula

$$ds^2 = dx^2 + dp^2 \qquad (4)$$

In practice, however, he must be content with the indirect measurement dt and must not expect even the simplicity of formula (1) We have assumed *flat* four dimensional space In curved space, XX and YY will become geodesics AA must know the value of the Riemann Christoffel tensor at every point along the path of the light and correct formula (2) accordingly

In the case of two observers whose world-lines

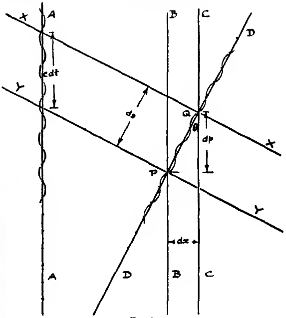

FIG 1

lie in the plane of the diagram and are inclined at an angle α, the transformation formulæ become

$$dt' = \frac{dt}{\cos\alpha}\{1 + \tan\alpha\tan\theta\}^{-1} \qquad (5)$$

$$dx' = dx\cos\alpha\{1 - \tan\alpha\cot\theta\} \qquad (6)$$

where $\theta = \tfrac{1}{2}\sin^{-1}\left(2\frac{dx}{cdt}\right)$

Formulæ (5) and (6) are derived from the relations

$$cdt'\cos\theta' = ds = cdt\cos\theta,$$
$$dx'/\sin\theta' = ds = dx/\sin\theta,$$
$$\theta' = \theta - \alpha$$

If we neglect powers of $\tan\alpha$ and of v, $=dx/cdt$, and write $u = c\tan\alpha$ the formulæ reduce to

$$cdt' = \frac{1}{\cos\alpha}\{cdt - dx\frac{u}{c}(1 + v^2 - \qquad)\} \qquad (7)$$

$$dx' = \cos\alpha\{dx - dtu(1 - v^2 - \qquad)\} \qquad (8)$$

If v^2 is neglected and β put in place of $\sec\alpha$, they correspond very closely to those of the Lorentz transformation as given in Eddington's "Mathe matical Theory of Relativity"

The question naturally arises Is the velocity of light a measure of the curvature of space and would it be infinite in flat space ? Assume that the measure

ment is made between two mirrors A and B at a fixed distance apart In a gravitational field the world lines of A and B will not be parallel Light leaves A at right angles and travels in a geodesic to B It returns starting at right angles to B and the return geodesic cuts A at A', which in general will not coincide with the starting point The difference in time which is due to the curvature of space will be taken as a measure (inverse) of the velocity of light Cannot the velocity of light be expressed in terms of the Riemann Christoffel tensor ? In formulæ (1) c is usually identified with the velocity of light, but AA will have to adjust the value of it if his acceleration of gravity changes and the latter is a function of the curvature of space

Intracellular Bodies in Plant Virus Diseases

IT has been known since 1903, when Iwanowski's paper on tobacco mosaic appeared, that virus disease in plants is frequently accompanied by the appearance within the cells of abnormal inclusions bearing some resemblance to amœbæ These inclusions, or 'X bodies', are well defined masses of granular or finely reticulate material not unlike protoplasm, typically rounded or roughly spherical in shape, though often elongated, and usually containing in their substance vacuoles, which vary in number from one to as many as ten or eleven The resemblance to amœbæ is heightened by the not infrequent appearance of lateral projections suggesting pseudopodia, and the occurrence of bodies constricted in such a fashion as to suggest fission has led several observers to believe that these X bodies are in fact living organisms or plasmodial colonies of organisms, which represent some stage in the life history of the virus parasite

Some fresh light has been thrown on the formation and nature of these bodies by a study of them as they occur in *Solanum nodiflorum*, when infected with the yellow or aucuba mosaic of tomato In this plant the hairs stand out stiffly from the leaves and lend themselves to examination in the living state, under quite high magnification, without further treatment than mounting the leaf in water or other suitable medium The bodies in the cells of infected hairs are unusually conspicuous, and ordinarily occur uncomplicated by the other abnormal structures, for example, striate material, crystal plates, etc, which are usual in the cells of mosaic tobacco, tomato or other plants, although a long crystalline spike is frequently seen lengthways in the cell They can be readily seen in cells of other type than the hair cells, for example, in epidermal or palisade cells of the leaf, but in these situations some operative interference is necessary to show them clearly

It was noticed by one of us (F M L S) that in the early stages of infection there appear in the streaming cytoplasm of the hair cells small particles, which are carried along in the stream and tend to aggregate together to the formation of larger masses, and it has been found possible to follow in the individual living cell the formation of the X-body from its early beginnings to its completion A young plant is inoculated and, when the first signs of the disease appear, a suitable leaf is detached, and under the microscope the hairs projecting from its margin examined seriatim The leaf is then placed with its petiole in water or nutrient solution, and examined again from time to time at short intervals, the appearance and development of the X bodies can be watched in selected individual hairs for many days

At the first examination, no bodies may be visible in any hairs In a few hours tiny particles appear in the cytoplasmic strands and are carried round the cell in the stream As time goes on, these particles increase in size, and at the anastomoses of the strands tend to hesitate or halt for a longer or shorter time before they move on, their further progress being facilitated by modification of the strands and by alteration in shape of the plastic particles themselves With still further increase of size, the halts become longer they may last for a couple of hours or more At such a halt another particle may join the stationary one, and when the movement is resumed the two may again separate or they may go on together as one mass By successive increments large masses are eventually formed which are readily recognisable as X bodies There may be several such masses in a single cell, which continue to move independently of one another, or they may coalesce to form one or more larger masses

These composite masses may remain permanently in union, and, when they do, they seem to fuse together, as it were, into a more homogeneous whole, in which vacuolation can be observed, even in quite small masses vacuolation is sometimes observable Sometimes, however, a composite mass may again separate, even after long contact, into its constituent parts which resume their independent movement When this occurs, figures are seen which look quite like a process of fission, but it is not a case of division in the sense of multiplication, since the separate portions may again unite Similarly, when a smaller mass breaks away from, or joins up with, a larger mass appearances may be presented which simulate pseudopodia, and have been so interpreted In leaves which have been infected for several weeks, breaking down of the bodies is comparatively common

This mode of formation accounts for many of the appearances which have led to the belief that X bodies are living creatures, for example, the pseudopodia, the fission figures, the occurrence of several bodies in one cell (which has been attributed to division of a parent body) It also explains the great tendency of X bodies to be associated in position with the nucleus, since it is round the nucleus that the protoplasmic strands cross and anastomose most freely, and it is in such situations that aggregation tends to occur Of the nature of the small particles themselves it is too early to say anything definite They give the impression of being foci where the protoplasm has condensed or solidified, and are of no fixed shape There is no sign of autonomous movement and nothing to suggest that either they or the complete body is living, in the sense of being an independent organism or parasite

The possibility that they are cytoplasmic condensations is strengthened by the fact that X bodies are protein in nature They give the usual protein reactions, such as Millon, Raspail, biuret, and various aldehyde tests, they are soluble in acid and alkali of sufficient strength, insoluble on boiling and in alcohol They have a distinct tendency to crystallise out, especially in old leaves, and the crystals have all the characters of protein crystals, such as are seen in aleurone grains, including the tendency to take semi-crystalline forms with faces and angles on only part of their surface In polarised light these crystals do not appear, nor does the uncrystallised body, though sometimes one or two small doubly refracting crystals may be seen lying on the surface of the body or embedded in its substance

Insect Pests of Willows

ALL plants of the genus *Salix* are attractive hosts for destructive insects In the case of basket willows, attacks of varying degrees of intensity are of annual occurrence A loss of 50 per cent is frequently experienced amongst willow growers, while at times insect invasion is so great as to render the crop totally worthless for basket making purposes

There is scope for extension of the willow growing industry in Great Britain for the following reasons

(1) The climate suits the willow crop, no other country being able to produce rods superior in quality to the best English grown varieties

(2) A considerable area of suitable land, now producing crops of little or no value, could be brought under profitable willow cultivation

(3) The demand of the basket making industry of the country for its raw material is not fully met from English sources, the annual value of basket making material and of basket ware imported being £170,000 and £400,000 respectively

(4) No willow rods are exported

In spite of the heavy losses due to insect attacks, the willow crop under average conditions is profitable, but it is probable if destructive insects could be kept reasonably in check the financial returns from the crop would be such as to make willow growing the most profitable amongst agricultural crops, and should extend and improve our basket making industry and ultimately result in English grown willow rods becoming an article of export

We are primarily concerned in this communication with an investigation on the life-history, behaviour, and methods of control of the principal willow pests To mention one or two, such as *Phyllodecta* species and *Galerucella luteola*, these produce damage in two ways the first and more serious by the attack on the growing terminal buds and resulting development of side shoots which ruins the rods, and secondly the impaired vitality of the plant through the loss of foliage by the adult and larval attack, and consequently causing considerable reduction in yields and quality

Galerucella luteola appears to be confined to *Salix triandra* varieties, and as this species of willow is grown extensively this beetle pest is frequently seen

Phyllodecta vitellinæ will attack many species of willow, particularly *Salix purpurea* and varieties, and *Salix alba vitellina*, whilst *Salix triandra* is never attacked

Phyllodecta vulgatissima appears to be confined to *Salix viminalis* varieties

The above three species of Chrysomelid beetles are major pests, and it is seen that the principal species of willows grown for basket work are attacked

Another pest, the bean gall sawfly of willows (galls are produced on the leaves by the oviposition of the sawfly *Pontania gallicola* Steph and occur commonly in huge numbers on *Salix triandra*, *S fragilis*, and *S alba*), is not considered by growers a serious pest, although cases occur when the crop of rods is weighed down to the ground by the mass of galls The damage is not always so obvious, but the gall formation when many leaves are attacked may cause a drain on the plant and probably results in reduced yields in the year of attack, and the vitality of the plant is impaired the following season

Briefly, the life history of this pest is as follows

The sawfly hibernates as a full grown larva in a waterproof cocoon under loose bark, etc, during the winter In spring the larva pupates and the adult emerges in early May, and oviposits in the terminal, unfolding leaves of the willow The gall very quickly develops and forms food for the larva inside, and the larva is full grown about the third week in June The larva cuts an exit hole in the gall and in due course pupates in cracks in the bark of willow stumps near the ground A second brood of adults appear at the end of July Still, sunny weather greatly facilitates oviposition and a large number of galls results It is this second crop of galls that cause the damage to the plant In mid September the majority of the larvæ are full grown and these go to their hibernation quarters

The second brood of sawfly larvæ is frequently attacked by Hymenopterous parasites, and in some seasons nearly every larva is found parasitised However, this natural control does not help the existing crop, as the damage has been done by the sawflies at the moment of oviposition, but possibly checks injury to the crop by reducing the intensity of the attack the following season

The bionomics of the above insect and other willow pests such as *Phyllodecta* sps, *Galerucella luteola*, the willow sawflies, and willow aphids are under investigation at the Research Station, Long Ashton

In the past the willow pests have not been studied in detail, and it is hoped that eventually a better knowledge of them will result in the returns for the willow growers being considerably increased

Raman Effect in the X-Ray Region

ATTEMPTS have been made to trace the Raman effect in the X ray region, the study of this phenomenon would be in this case very interesting because it would be a purely electronic effect due to variations in the stationary positions of the electrons Experimental results, however, are not consistent, Bergen and Davis (*Phys Rev*, **33**, 338, 1929) succeeded in obtaining, besides Compton radiation and the line of the same frequency, other radiations which can be well interpreted as Raman radiation These workers experimented with carbon and beryllium as the diffusing substances and used an ionisation camera, other workers using photographic methods did not obtain any Raman effect (Ehrenberg, *Zeit fur Phys*, **53**, 234, 1929) Similarly, Kast (*Zeit fur Phys*, **58**, 519, 1929), using aluminium as diffusing substance, found nothing but the classical and Compton radiation

It should be noted that the Raman electronic effect will appear in the X ray region under the following conditions the electron in one of the Röntgen levels K, L, M must be able to pass from one of these levels to an X level which is not yet filled up, or to an optical orbit at the periphery of the atom In both cases the substance showing the effect must show the so called semi optical lines, that is, absorption lines in the X ray region Such lines show themselves as a fine structure at the limits of the continuous absorption bands It should be noted, however, that not all the elements showing such fine structure can present this effect, because, as modern researches have proved, such fine structure is frequently due to a process of double ionisation On the contrary, a substance suitable for the study of this effect would be argon, because, as Coster (NATURE, **117**, 586, 1926) has shown, in this element the passage of an electron from an orbit K to an orbit $2p$ has been controlled

We have examined the question theoretically and calculated the intensity to be expected, and we give here the essential results The problem has been treated like the problem of the Compton effect, which has been already explained with great success by Wentzel (*Phys Zeit*, **43**, 1 779 and,

1927) and Sommerfeld ("Atombau Wellenn Erg", p 251) Supposing that an electron could pass from an orbit K, L . to an optical orbit, we approached the problem using Schrödinger's functions ψ relative to the H, assuming that the exciting frequency is much larger than the frequency of the limits of absorption In these conditions, we have obtained by calculations that the intensity of the Raman lines is different according as the initial state is K or L or M level and the final state is the optical level $1s$, and is also different if the final state instead of $1s$ becomes the state $2p$ We have found that, indicating by E_e the kinetic energy of the electron emitted for the Compton effect in one particular direction of observation, and with one particular exciting frequency, the intensity of the Raman line for an element of atomic number Z observed along the same direction is proportional to the quantity

$$Z^{-2}\left(1+\frac{E_e}{|E_\mu|}\right)^{-4}$$

where $|E_\mu|$ is the energy of the K level if the jump is $K \longrightarrow 1s$ As the intensity of the undisplaced line is proportional to

$$\left(1+\frac{E_e}{4|E_\mu|}\right)^{-4}$$

we see that the relation of the intensity of the Raman line to the undisplaced line is practically inversely proportional to the cube of the atomic number More complex expressions have been obtained for the jumps $L \dashrightarrow 1s$, $M \dashrightarrow 1s$ If the final optical orbit is a level $2p$, then the intensity is proportional to Z^{-6}

From our theoretical investigations we conclude that to observe this effect it is necessary (1) to use substances presenting semi optical lines, (2) to use substances of low atomic number, (3) to use exciting wave lengths, directions of observations, and substances for which the relation $\frac{E_e}{|E_\mu|}$ is very high

Details of calculations will be published elsewhere

Existence of two Limits of Predissociation in the Nitrogen Peroxide Molecule and the Heat of Dissociation of Oxygen

THE absorption spectrum of nitrogen peroxide vapour is composed of two regions the first from the red to about 2900 A , the second from 2596 A to about 2200 A These two regions correspond to two different electronic activations of the molecule

The first region is made up of a large number of bands and fine lines having a very complicated structure, which we are studying now with L Harris From the visible up to about 3700 A the bands are very fine with quite definite rotation lines , there are two or three fundamental vibration frequencies But between 3800 A and 3700 A the bands become broad and diffuse, the fine structure disappears This corresponds to the first limit of predissociation

In the second region we have obtained with L Harris between 2596 A and 2459 A a series of bands with a fine structure corresponding to a very clear double rotation spectrum , at $\lambda = 2459$ A, the bands become abruptly diffuse and broad and up to 2200 A there are nine such bands This is the second predissociation limit.

The physical interpretation of these two predissociation limits is that they correspond to the two limits of dissociation of the nitrogen peroxide molecule into nitric oxide and a *normal* or an *activated* oxygen atom

The corresponding energies are

(1) $NO_2 \longrightarrow NO + O$ − 77,000 cal (3700 A)
(2) $NO_2 \longrightarrow NO + O^*$ − 116,000 cal (2459 A)

The first is in exact agreement with the results obtained by Norrish (*Chem Soc* , June 1929), who obtained a photochemical dissociation of NO_2 into NO and O_2 by light of $\lambda = 3650$ A , and no action by $\lambda = 4300$ A , the light of $\lambda = 4050$ A giving a very slight reaction

From these results, the heat of dissociation of the oxygen molecule can be calculated

$$O_2 \longrightarrow O + O - 128{,}000 \text{ cal } (5\ 5 \text{ volts}),$$

and the activation of oxygen atoms

$$O \longrightarrow O^* - 39{,}000 \text{ cal } (1\ 7 \text{ volts} = 13{,}700 \text{ cm}^{-1})$$

The dissociation energy of the oxygen molecule was calculated first by Birge and Sponer as 163,000 cal (7 1 volts), then corrected by Birge (*Phys Rev* , **34**, 1062, Oct 1, 1929), Bristol meeting of Faraday Soc (Sept 24, 1929) to 5 6 − 6 5 volts, by Kassel (*Phys Rev* , **34**, 817 , 1929) to 5 0 − 5 5 volts, and by Mecke (*Naturwissenschaften*, Dec 20, 1929) to 5 6 volts

The active oxygen obtained from the second predissociation limit is probably in the metastable ^1D state

The value $^3P_2 - {}^1D$ is not known for oxygen , R Frerichs (*Phys Rev* , **34**, 1239 , Nov 1, 1929) gives a probable value of 15,500 cm $^{-1}$, McLennan (NATURE, Dec 7, 1929, p 874) has calculated by analogy with selenium and tellurium spectra a value of 10,587 cm $^{-1}$.

Our value is therefore the mean of the two

Tides of the Upper Atmosphere and the Heights of Meteors

IN NATURE of Dec 14, 1929 (vol 124, p 913), the result of an examination of some data giving the heights at which the meteors disappear has been published There seemed to be a variation of these heights with the lunar hour angle By kind information from Dr G M B Dobson my attention was directed to a great number of observations of the heights of meteors given by Mr W F Denning in *Monthly Notices of the Roy Astron Soc* , March 1912 and January 1916 These observations (556) were divided into 6 groups and treated in the same manner as the former Using the same designations as in the former letter, the following values were found for the mean height at which the meteors disappear

Flood tide	46 9 ± 1 8 miles
+ 0	47 0 ± 1 1 ,,
− 0	49 2 ± 1 9 ,,
Ebb tide	49 1 ± 0 8 ,,

The mean error is derived from the 6 group means Examining in the same manner the heights at which the meteors appear, the following values for the mean height are found

Flood tide	70 1 ± 2 2 miles
+ 0	67 5 ± 1 9 ,,
− 0	70 8 ± 2 6 ,,
Ebb tide	71 6 ± 1·0 ,,

From the result of the former letter it would be expected that the mean height for flood tide (and + 0) should be greater than that for (− 0 and) ebb-tide, both for the heights referring to the disappearance of the meteors and for the heights referring to the appearance This is in no way the case; on the con-

trary, from the above tables it will be seen that the values for flood tide (and +0) are smaller From this it may be concluded that the result given in the former letter is due to an exceptional (but nevertheless an accidental) distribution of the heights examined A further examination has also shown that the numbers of heights under 55 km for flood tide, +0, −0, and ebb tide are 2, 3, 9, and 7, respectively The relatively great numbers for −0 and ebb tide have caused that an amplitude with a comparatively small mean error was found

After this it does not seem possible to obtain any trustworthy information as to the tides of the upper atmosphere from the meteor observations used hitherto, but it ought to be remarked that the highest meteors are not easily observed, and this circumstance might have influenced the result In this connexion, attention may be directed to the fact that, while the mean height for disappearance was 85 km in the former case, the mean height derived from the present data is 48 miles or 77 km, and, furthermore, that the number of observations for flood tide and ebb tide in the present case are 172 and 200, respectively

In NATURE of April 27, 1929 (vol 123, p 642), some results are given, which are based on an examination of the two maxima of the frequency curve of the heights of the bases of aurora This investigation led to the result that these maxima are due to the tides of the upper atmosphere It should be of great interest to learn whether new series of observations of the heights of the bases of the aurora confirm the existence of the peculiarity of the older series

Natural Control of *Lucilia sericata*

AT the Farnham House Laboratory of the Imperial Bureau of Entomology, experiments are being carried on to determine the value of the braconid parasite *Alysia manducator* Panzer as a controlling agent of the sheep blowfly, *Lucilia sericata* Meigen Preliminary studies of the bionomics of the host have been in progress for nearly a year

The potential rate of reproduction of *Lucilia sericata* is very high Eight females the oviposition of which was followed completely laid an average of 1561 5 eggs, the most prolific of them depositing 1883 The eggs are almost completely viable, and large numbers can be reared to the adult stage with the loss of only 1 or 2 per cent In critical experiments this loss is kept below 1 per cent and in many cases can be quite eliminated Obviously such a high rate of reproduction is by no means attained in Nature Parasites play a part—at certain seasons of the year an important part—in the control, but the reduction seems to be principally brought about in another manner

In laboratory experiments it is found that if increasing numbers of eggs of the same age are placed on equal portions of meat under identical conditions, the increasing rigour of starvation has three effects (1) the size of the adults obtained becomes gradually smaller, (2) the mortality during the larval period gradually increases, (3) beyond a certain point fewer adults are obtained than the amount of food supplied is capable of supporting The last result may be attributed to the use of food by many first and second instar larvæ that are never able to complete their development, but deplete, by feeding, the amount of food available to those that are able to mature

During September and October 1929 this matter was studied under field conditions at Farnham Royal It was first ascertained that exposed meat is soon overblown In one case, 156 gm of meat exposed in bright sunshine bore 5645 eggs, principally of *Lucilia sericata*, after only five hours, although this amount of food could support no more than 1560 normal individuals Mice, rats, and guinea pigs were similarly provided in a few hours with far more eggs than could develop on their tissues Moreover, oviposition continued for at least ten days on animal remains from which thousands of half grown, starving larvæ were already migrating It was then determined that from pieces of beef and whole small mammals, exposed in both sunny and shady situations and known by observation to have been provided with immense numbers of eggs, comparatively few adults were obtained, fewer, in fact, than could have developed on the same food had a smaller number of eggs been laid

It appears, then, that the high reproductive rate of *Lucilia sericata* is largely offset by its habit of laying more eggs on a carcass than the latter can support This results, it is to be noticed, not only in the loss of the surplus eggs, but also in the death of individuals that would have survived had the additional eggs not been laid

Crossed Connexion of the Cerebral Hemispheres with the Muscles and Sense Organs

THE crossed connexion of the mammalian cerebrum with muscles and sense organs is a condition derived from a more primitive state of the nervous system Thus, Ferrier found [1] that stimulation of the brain in frogs and fishes caused movements of the opposite side of the body That the crossing is a general phenomenon is shown by the crossing of nerve fibres in the nervous system and the decussation of the optic nerves in all vertebrates [2]

The crossed relationship is suggestive of an optical effect as the image (when real) of an object is always inverted, that is, on the opposite side of the optical axis In order that this optical inversion can be a factor in the development of the nervous system it is necessary to look for a primitive animal with a single median eye An example of such an animal is the larva of a simple ascidian in which an unpaired optic organ is present and the region where the images would be formed is represented by the enlarged anterior extremity of the nervous system [3]

The image of an object on the right of such an animal would be formed on the left side of the retina, and by a movement of the muscles on the right side of its tail it would move so that the image would be central By repeated correlation between stimulation due to an object and the movement to bring the image of it on the centre of the retina a relationship would be established in the same way that a conditioned reflex is developed

After such a relationship had been established, all those portions of the nervous system which grew out from that part of the nerve mass would show a crossed relationship This view is frankly Lamarckian, as it implies the inheritance of a relationship developed in response to a functional association

The cerebrum in man shows a further relation to optical projection as the upper margin of the calcarine fissure corresponds to the lower half of the visual field and the lower margin to the upper half, but the

architecture of the human cortex is too far removed from the primitive state to be used as an argument in support of the view that the contralateral connexions in vertebrates are the result of the formation of optical images in an unpaired median eye

The above suggestion may not be new, but it is not well known, and I have never heard of it There is no means by which it can be put to the test by experiment Ascidians are degenerate forms, but their larvæ may not be far removed from the primitive vertebrate stem

The Muscular Sense

I HAVE just seen Col Lynch's letter in NATURE of Jan 11, in which he criticises mine, which dealt with the muscular sense In order to experience a sensation, surely no "analysis of a searching character" is required, else the state of the child and of the savage would be peculiarly unfortunate In my letter in NATURE of Nov 23, I merely wished to describe a method involving no apparatus which permitted one to experience sensations produced by the activity of muscles engaged in raising or lowering the mass of the limbs I am aware that some psychologists have discussed the question whether these sensations in or of muscles are not rather sensations of the outgoing, cerebral, efferent impulses to the muscles I have always thought that view extremely unlikely and akin to learned trifling If it were true, would it not be very peculiar that we should not have any awareness of any other kinds of efferent innervations such as those of heart, blood vessels, or glands?

I did not set out to offer any "explanation" of the muscular sensation which involved or did not involve "a minute examination of a long series of neurological phenomena"

I still think the method I have described is an interesting one, because it is, to some extent, quantitative, in that the moment the limb rests on the water the sensation is minimal, and the moment it begins to be raised or lowered the sensation is increased in intensity I hope we may still be allowed to experience and report on sensations without being compelled to give "a valid analysis" of them "with the necessary rigour"

Sterilisation as a Practical Policy

MAY I add to the admirable review by Prof MacBride (NATURE, Jan 11, pp 40 42) that there is an urgent and immediate place for voluntary sterilisation in Great Britain side by side with voluntary birth control? The medical profession at present does not meet the demand of those conscious of heritable defect and with a sufficient sense of civil responsibility voluntarily to desire sterilisation Compulsory sterilisation of the unfit would require legalisation which we may properly hope may be passed before long, but to secure the voluntary sterilisation of those ready to ask for it requires such public propaganda as was given to constructive birth control But while it is easy to sterilise a male effectively and harmlessly, it is neither so easy nor so successful, as Prof MacBride's article would lead one to believe, to sterilise the female, the tying of the Fallopian tubes sometimes leading to internal pregnancies which are worse than the normal Nevertheless, as a social step it will be valuable to facilitate voluntary sterilisation even of the defective males who are conscious of their defect and willing to have vasectomy performed

The Society for Constructive Birth Control has for some time past been considering the possibilities for facilitating this and will be pleased to hear from competent surgeons willing to undertake such cases in any part of the country

Botanical Nomenclature

MAY I request the publication of a short note which I consider a point of importance in view of the forthcoming botanical conference in Britain?

Article 57 of the Vienna rules states "the original spelling of a name must be retained except in case of a typographic or orthographic error" The use of the word "spelling" along with the word "orthographic" in this sentence appears to many to override the original meaning of the latter word, namely, "correct writing", and to restrict it to the dictionary sense of correct spelling alone But correct writing is equally important with correct spelling To avoid ambiguity, I suggest Article 57 be amended to read "typographic, orthographic or syntactic error"

Is a man to be allowed to write sav, "ein schoner Buch" in German, or "une beau fille" in French, through ignorance or temperamental whimsy, without protest from lovers of good German or French? Why, then, should we allow our 'nodding *Homer*' of nomenclature, even, to palm off on us an orthographic blunder such as *Polygala sanguinea* instead of *P sanguineum*, or pass by uncorrected a recent new specific blunder like *Airosperma fusca* for *A fuscum*?

Spectrum of Trebly Ionised Krypton

A SHORT note by me on the spectrum of doubly ionised krypton was published in NATURE of Feb 16, 1929 (vol 123, p 244) Since then the observational data with regard to the spectrum of krypton have been extended up to λ1930 A on the ultra violet side In the region of about 41,000 frequency units, some very strong lines, namely, 42,475 1(10) and 40,560 3(9), have been observed Although the lines of Kr^{++} due to the transition $3N_2(O_2 \leftarrow O_2)$ had been located near this region, it did not seem probable that this transition would give rise to such intense lines—lines more intense than the fundamental lines due to $3N_2(O_1 \leftarrow O_2)$

Further, by extrapolation by the method of horizontal comparison, it has been found that the fundamental lines of Kr^{+++} due to the transition $2N_2(O_1 \leftarrow O_2)$ would lie in this region

An attempt to find out these lines of Kr^{+++} has revealed a number of multiplets The lines 42,475 1(10) and 40,560 3(9) have been found to be the ${}^4P_3 - {}^4D_4$ and ${}^4P_2 - {}^4D_3$ lines

A complete analysis of this spectrum is in progress and will be published shortly

The Raman Effect

By Dr A C MENZIES

INTRODUCTORY

IT is now just two years since the effect known by his name was discovered by Sir Chandrasakara Raman,[1] but the phenomenon has aroused so much interest that even in this short time a tremendous amount of work has been done A summary, therefore, at this stage may serve a useful purpose

In brief, the effect may be thus described When a beam of monochromatic light is directed into some transparent substance, some of the light is scattered, and this light has the same frequency as the incident light (unmodified scattering) In addition, a much smaller quantity of the light suffers a change of frequency, usually a diminution (modified scattering), and it is this which constitutes the Raman effect The magnitude of the change is found to depend upon the nature of the scattering material and is independent of the frequency of the incident light In general each exciting line evokes several modified lines, some of which may be plane polarised

On account of their superficial resemblance, it would be well to make clear the respects in which this effect differs from fluorescence

(a) In fluorescence, the frequencies of the fluorescent spectrum are independent of those of the exciting radiation, provided the latter are able to excite fluorescence at all On the other hand, the frequencies of the radiations modified by Raman scattering are directly related to the incident frequencies ν_i, being $(\nu_i \pm \nu_R)$ These shifts, ν_R, are either actual infra red frequencies in the absorption spectrum of the scattering material, or differences in such frequencies [2, 3] For example, measuring wave numbers in cm^{-1}, the frequencies 27354, 27290, 24704, and 22939 emitted by a mercury vapour lamp are scattered by benzene molecules and give rise to the Raman lines (among others) 24294, 24231, 21646, and 19877 respectively These, it will be seen, are lines shifted to the red by an amount 3060 cm^{-1} approximately, and correspond to an infra red wave length 3 27 μ, while the infra red absorption spectrum of benzene includes a a strong band at 3 25 μ

(b) The intensities of the Raman lines are of a different order of magnitude

(c) Many of the Raman lines are strongly polarised

TECHNIQUE

The first observations were made with complementary light filters, but this was abandoned in favour of spectroscopic methods The light from a mercury vapour lamp is directed by a large condensing lens into a flask and the light scattered at right angles is focused on to the slit of a spectrograph (flask method) This has been modified by R W Wood,[4] who uses a long tube, water cooled, placed parallel to a long tubular mercury arc and almost touching it Observation is made axially along the tube, and portions of the spectrum of the incident light may be filtered out by the addition of suitable colouring matter to the cooling water (tube method)

As a source for Raman scattering experiments, the mercury vapour lamp has the disadvantage that it cannot be arranged to give really monochromatic radiation For this reason, helium excitation is sometimes used,[5] since the strong line λ3888 A U can be isolated by ultra violet glass and the results are then unambiguous

Although most observations have been made in the visible region, the ultra violet region has been used as well, entailing the use of quartz throughout This region has the advantage that the Raman lines are considerably stronger It must be borne in mind, however, that chemical action may easily be induced by the use of such short wave exciting light, and the experiment thereby vitiated

When gases are to be investigated, the tube method is used, and the exposure may be shortened by having the gas under pressure

In the case of solids, a block is treated as in the flask method Recently, it has been shown by me [6] and independently by Bar [7] that the Raman spectra of solids in powder form may be obtained, since the incident radiation is much weakened by repeated reflections Thus the field for investigation is considerably greater, since only a few solids are obtainable in large pieces

WIDTH OF LINES

The scattered lines differ greatly in respect of width [8, 9] When scattered by crystals, the lines are particularly sharp, less sharp for amorphous solids, and some lines scattered from liquids are more diffuse still The change in sharpness in the transition from solid to liquid is well shown in the liquefaction of ice [10] In this case the lines become much broader when the ice melts, but with little alteration of frequency This, as pointed out by C P Snow (private communication), means that ice is a molecular lattice and not an ionic one In some liquids the lines are very sharp indeed, but quite frequently a continuous spectrum [11] is obtained, especially in very viscous liquids The unmodified lines are often diffusely broadened, this is perhaps to be accounted for as a Raman scattering where the incident radiation has been modified by the abstraction of energy required to produce changes in the rotational frequencies of the molecules [12]

INTENSITIES

If corresponding Raman lines (that is, lines having the same frequency shift from the different exciting lines) be considered, the intensity is augmented considerably as the frequency of the exciting line is increased It does not, however, follow the fourth power law [13] The Stokes lines (shifts to the red) are very much more intense than the corresponding anti-Stokes lines [14, 15] The ratio of the intensities of corresponding Stokes and

anti-Stokes lines has provided an interesting criterion for the quantum theory of dispersion Schrödinger's original dispersion theory implies an intensity-ratio equal to one[16] Statistical mechanics, however, yields intensity ratios in accordance with those observed[17 18]

EFFECT OF TEMPERATURE

Intimately connected with the consideration of the intensity-ratio just mentioned is the effect of change of temperature Whatever the true explanation of the Raman effect may be, jumps between quantised states must be involved and intensities will be affected by the molecular populations of these states So increase of temperature, which favours an increase in population in the higher states, is bound to augment the intensities of the anti-Stokes lines, and this is found to occur[19] In quartz, for example, a particular Stokes line has an intensity about two fifths of that of the corresponding unmodified line As the temperature is increased, the unmodified line increases in intensity, the anti Stokes line increases more rapidly and the Stokes line decreases slightly in intensity[20 21] At the same time, the lines become more diffuse, this has been attributed to an increase in the molecular rotation[22]

CRITICAL STATE

Ordinary unmodified scattering increases very considerably in intensity as the critical state is approached, but there is little corresponding increase in the intensity of the modified radiations This is taken as a proof that the modified radiations are incoherent[23, 24]

POLARISATION

In scattering by liquids, the modified lines may be plane polarised parallel to the direction of polarisation of the unmodified lines, partially polarised in this direction, or unpolarised[1 25] In scattering by solids, it is possible in addition for modified lines to be plane polarised in a direction perpendicular to that of the unmodified lines This has been shown to occur in quartz, and is related to the direction of the optic axis with regard to the directions of the incident and scattered beams A new orientation of the crystal produces a change in the direction of the plane of polarisation for some of the lines, but not for others[26 27]

SCATTERING IN GASES

It has been suggested that many of the weak lines listed in spectrum tables may be Raman lines excited by strong lines of the element involved For example, H S Allen suggests that some of the secondary lines of hydrogen may be Raman lines excited in the molecules by Balmer lines[28]

Hydrogen chloride gas gives a sharp Raman line corresponding to the 'missing' line in its absorption spectrum, together with some lines corresponding to molecular rotations[29] It is interesting that the changes in the rotational quantum number m for the Raman spectrum of HCl gas are given by

$$\Delta m = 0 \text{ or } \pm 2,$$

while in the infra-red absorption spectrum they are given by

$$\Delta m = \pm 1$$

This fits in with the 'three level' theory discussed later

Carbon monoxide gives a line corresponding to the infra red absorption band, while carbon dioxide gives two lines which correspond to the *differences* in frequency of the components of the doublet infra-red absorption bands[8]

Oxygen, hydrogen, and nitrogen scatter the exciting line with several equally spaced lines on either side, these are found to be due to changes in molecular rotational energy, with alternate rotational levels missing or relatively weak In oxygen the lines are due to transitions between odd levels only, in hydrogen the lines due to transitions between odd levels are strong, while those between even levels are weak, and in nitrogen the intensities are reversed[30] The difference between the three gases in this respect may be made clearer by the use of heavier type to indicate larger intensities

Oxygen	**odd**	
Hydrogen	**odd**	even
Nitrogen	odd	**even**

It is remarkable that in this respect nitrogen should be unlike hydrogen, for from the point of view of nuclear states one would expect them to be similar

In nitrogen monoxide a Raman line has been photographed corresponding to a change in the direction of electronic spin[31]

Oxygen, hydrogen, and nitrogen were first examined in the liquid state,[32] and in the case of hydrogen two quantum transitions in the molecular rotation were observed, and a one quantum vibrational transition The rotational transitions are $0 \rightarrow 2$ and $1 \rightarrow 3$, the molecules being in the zero vibrational state This is evidence of the existence of both the α and β forms in liquid hydrogen

SCATTERING IN LIQUIDS

The effect was first discovered with liquids, and it is with the scattering material in this state that most of the work has been done With the exception of the work on liquefied gases just mentioned, the results obtained with liquids have been important more with regard to the infra red spectra and chemical constitution of the material than to the elucidation of the effect itself It would be impossible here to refer to many of the papers dealing with liquids, a comprehensive memoir has lately been published by Ganesan and Venkateswaran[33]

As an example of the use of the effect for the study of chemical constitution we may consider the C-H bond This bond is found to involve a Raman shift corresponding to 3 35 μ in tetrachlorethane for example, but when the carbon has a double bond, the C H line is displaced towards the shorter wave-lengths, for example, 3 25 μ in trichlorethylene[34, 35] In a similar way other Raman shifts are connected with chemical linkages In

the instance just quoted, Raman effect measurements are supported by infra red observations, unsupported evidence should be treated with caution, since Raman shifts correspond so frequently to the difference between frequencies rather than to the frequencies themselves

Solutions of salts in water show Raman lines characteristic of the salts in addition to those due to the water As an example of work on solutions may be quoted the recent interesting experiments of I R Rao with nitric acid at different concentrations[36] Lines were found with the concentrated acid, due to the NO_3 ion, as well as lines attributed to HNO_3 On dilution, the NO_3 lines intensified up to a maximum and thereafter diminished in intensity, while the HNO_3 lines progressively grew weaker and faded out altogether The dilution at which the HNO_3 lines disappeared was the same as that at which the intensity of the NO_3 lines was a maximum Thus, literally an ocular demonstration is provided of the increase of ionisation in a solution when it is made more dilute

SCATTERING IN SOLIDS

Quartz and iceland spar were investigated by Landsberg and Mandelstam,[37] who claim to have discovered the effect independently of Raman one of the shifts found by them in Iceland spar corresponds to the optically inactive fundamental frequency of the CO_3 ion Such inactive frequencies occur with great strength in the Raman effect in crystals, they may be observed easily using the crystals as a coarse powder, or in solution

When water of crystallisation is present, the water Raman lines are found, and are considerably sharper than in water itself

Raman lines corresponding to the residual ray frequency of rock salt are *not* found, nor do the residual ray frequencies appear in the Raman effect investigation of lithium or sodium fluoride Schaefer[38] suggests that the Raman effect implies an asymmetrical vibration, while the lattice vibration of NaCl is essentially a symmetrical vibration

THEORY

The original theory as put forward by Raman was that the modified lines were displaced by an energy amount equal to that required to raise a molecule from the normal state to some higher energy state If this were so, all Raman lines would correspond to infra-red absorption lines, and this is certainly not the case The modified lines are implicit in the Kramers Heisenberg[39] dispersion formula, which was developed from the theory of Smekal[40] The existence of the effect was nevertheless not sought for, and remained to be discovered quite independently

The modified lines differ in frequency from the exciting lines by an amount equal to a difference in frequency between infra red absorption lines The absorption lines themselves may appear, but they are usually very weak Three levels are involved in the production of a single Raman line, say k, l, and n If transitions may take place between k and n, and between l and n, then a Raman line may be expected corresponding to the transition between k and l, even though this may be a forbidden transition in the infra red[3, 41] Thus it is at once explained why Raman lines exist having no counterpart in the infra red, and vice versa As the energy of the exciting quantum approaches the value $(E_n - E_k)$, the Raman scattering becomes increasingly intense, and when it reaches it, fluorescence occurs[42]

The theoretical explanation of the polarisation of the lines is not yet fully understood Raman has sought to explain it in terms of the optical anisotropy of the molecule,[12] while I have endeavoured to picture it in terms of the energy transitions between directions of vibration which have different orientations in the molecule[27]

FUTURE PROGRESS

Although a great deal has been done, much remains for investigation The polarisations of the lines, the relative intensities of the Stokes and anti Stokes lines, and the energy levels of molecules deduced from the Raman effect observations combined with infra red work, are a few of the lines of investigation which will provide work for many investigators There is little doubt that when its usefulness is appreciated, it will be constantly employed by the research chemist

A bibliography of 160 papers has been published by A S Ganesan (*Ind J Phys*, **4**, p 281, 1929) and in most cases an abstract of the paper is given This bibliography deals with papers published up to July 1929

The *Transactions* of the Faraday Society dealing with the conference on molecular spectra, just published, contains several papers dealing with different aspects of the Raman effect.

Malaria Prophylaxis in Kenya.[1]

IN the years 1925, 1926, 1927 there were in Kenya at least 10, 10, and 5 deaths, and in Uganda at least 19, 48, and 22 deaths from blackwater fever in the respective years This is a deplorable waste of life, for it may be regarded as axiomatic that malaria and blackwater fever are so closely connected that freedom from the former means absolute freedom from the latter Blackwater fever to-day in Africa, as it did nearly a century ago, kills twenty-five in every hundred of those attacked, and yet, says Col S P James in the report before us, "Several people told me, with obvious pride, that they had had two or more attacks of the latter disease" [blackwater] (p 24) This century long waste of life, in spite of the "obvious pride" of the ignorant, is a totally unnecessary sacrifice It is unnecessary because malaria (and so blackwater) is a preventable disease, but now we are rejoiced to hear that this slaughter will cease in Kenya, for "the Governor had announced that it was his Government's intention to stamp out the disease" (malaria) With it will also disappear blackwater not only from among Europeans but also from among the Indians, of whom there are three times as many in Kenya as there are Europeans, and among whom the incidence and fatality of blackwater is surprisingly high (p 29)

Now "although the Kenya Government had taken various measures within the limits imposed by financial considerations and available staff, the disease [malaria] was still a serious menace" (p 5) Col James points out that the campaign (now to be undertaken) will be long and difficult, it must, in the words of H R H the Prince of Wales, be "intensive and scientifically conducted" How far these conditions are compatible with financial considerations remain to be seen So recently as 1926, Mr Ormsby Gore[2] stated "that malaria can be controlled is well known, but the difficulty and expense of such control, in view of the extent of the West African colonies and the conditions which prevail in those territories, are almost insuperable" (p 67)

Whether or no we can stamp out malaria remains to be seen, but if we try to do so, we should at least use the best methods available It is true that malaria has been 'stamped out' (we ourselves prefer a less ambitious word, 'moderated') here and there in various parts of the world, but it is unfortunately also true that no general wide spread success has attended the efforts of sanitarians Perhaps a clue to the whole situation is afforded by the example of malaria in Great Britain itself Ague has disappeared from the country Perhaps the most satisfactory explanation is that it has disappeared as the result of improved social hygiene Poverty, dirt, malnutrition, ignorance, have been replaced by wealth, cleanliness, well-being, and education to such an extent as to mitigate completely its ill effects Drainage and agriculture and improved housing also play their part Whatever be the exact cause, malaria for all practical purposes disappeared long before antimalarial campaigns were heard of, nor is this an entirely exceptional occurrence

Col James in this report lays great stress again on the view, so ably defended by him, that the methods of malaria prophylaxis are not simply those of the 'Aquatic school' (pouring paraffin on pools), or of the 'Mithridatic school' (poisoning the parasite with potions), if we may use these terms without disrespect, but that while both these methods have their (limited) usefulness there is something more, namely, the great malaria problem is one of social hygiene in its widest application and that mere prophylaxis as usually carried out is not likely to succeed until this is realised Poverty then must be stamped out by wealth, and ignorance by knowledge, malaria also will be stamped out in the process The practical advice given in this report will be of great value to those directly concerned with the actual administrative problems that arise in such a vast undertaking and high aim as the Kenya authorities have in view

[1] Report on a visit to Kenya and Uganda to Advise on Antimalarial Measures By Col S P James Pp 48 (London Crown Agents for the Colonies 1929) 1s

[2] Report by the Hon W G A Ormsby Gore (Parliamentary Under Secretary of State for the Colonies), on his visit to West Africa during the year 1926 (London H M Stationery Office)

Obituary.

PROF KARL VON DEN STEINEN

BY the death of Karl von den Steinen on Nov 4 last, ethnological studies in Germany have lost one of their most distinguished and widely known representatives Born at Muhlheim a Ruhr in 1855, he graduated at Düsseldorf in 1871 and studied medicine at Zurich, Bonn, and Strasbourg While travelling round the world from 1879 to 1881, he met Adolf Bastian in Hawaii Association with that distinguished and enthusiastic ethnologist turned his attention to the study of primitive cultures, especially those of Polynesia.

It was not, however, until 1884, after his return from South Georgia, where he had been attached to the German party in charge of the meteorological station, that von den Steinen definitely turned to anthropological exploration He then organised an expedition through Central Brazil and explored the then unknown region of the Xingú, one of the southern tributaries of the Amazon The results of this expedition were embodied in his book "Durch Zentral Brasilien" He returned to the Xingú in 1887, publishing the results of his intensive studies of the natives of the area in his grammar of the Bakairi language in 1892, and in his "Unter den Naturvölkern Zentral Brasiliens" in 1894

For long von den Steinen was best known to the

outer world for his work in South America, but his interest in the culture of Polynesia never flagged In 1897 he visited the Marquesas and in 1898 the tribes of north western Canada His studies in Brazil had interested him in the problems of primitive art, and this interest was intensified by the curious art forms of the Marquesas From this time forward he devoted himself to the accumulation of material for the study of the history of Marquesan art The result was his monumental work on Marquesan art, of which the first volume appeared in 1925 and the second in 1928—a work which cannot but have a profound effect on method in all future studies of primitive art

Von den Steinen's life was devoted to research, but he held a chair in the University of Marburg from 1891 to 1892, was president of the German Geographical Society in 1896, director of the South American department of the Ethnographical Museum in Berlin from 1902 to 1906, and president of the Anthropological Society of Berlin from 1908 to 1910 He was elected an honorary fellow of the Royal Anthropological Institute so long ago as 1905

Prof Auguste Rateau

With De Laval, Sir Charles Parsons, Curtis, and Ljungström, the late Prof Rateau, who died in Paris on Jan 13, will be remembered as one of the successful pioneers of the steam turbine So long ago as 1890 he published his "Études sur les turbines à vapeur", in 1896 he patented his well known form of multi stage impulse turbine, in 1900 at the Paris Exhibition he exhibited complete designs for a turbine installation of a torpedo boat, and in 1903 he founded the Société Rateau, which from small beginnings rapidly grew into a large undertaking employing some three thousand workmen, with branches in all European countries Though the turbine claimed the greater share of his attention, he did most successful work on the compound centrifugal air compressor, while his turbine super-charger has been fitted to aero engines and to marine Diesel engines

Born at the small town of Royan, near the mouth of the Gironde, on Oct 13, 1863, Rateau attended the grammar school at Cognac and then spent some years as a student, first at the École Polytechnique and then at the École Supérieure des Mines in Paris, gaining the rank of Inspector of Mines in 1886 He was already distinguished by his high attainments, and in 1888 was appointed a professor at the Mining School at St Étienne, about ten years later he returned to Paris as a professor of electrical engineering in the École Supérieure des Mines

It was Rateau's early work on mine ventilation which laid the foundation of his work on turbines and turbo blowers Of world wide reputation, he read papers in England to the Institution of Mining Engineers, the Institution of Naval Architects, and the Institution of Mechanical Engineers, and during the James Watt centenary celebrations in 1919, with other distinguished engineers, received the honorary degree of LL D from the University of Birmingham He was likewise honoured by places so far apart as Charlottenburg, Wisconsin, and Louvain, while he was one of the few engineers to be elected a member of the Institut de France

We regret to announce the following deaths

M Maturin L Delafield, originally of New York, who for the last twenty five years has resided in Lausanne, known for his work on the taxonomy of vascular plants and on phytogeography, on Dec 18, aged sixty years

Mr E T Newton, F R S, formerly palæontologist to the Geological Survey of Great Britain, on Jan 28, aged eighty nine years

Dr J M D Scott, professor of physiology in the University of Saskatoon and formerly lecturer and senior demonstrator at St Bartholomew's Hospital Medical School, London, on Jan 28

News and Views

The centenary of the birth of Lord Salisbury, who delivered a noteworthy address as president of the British Association at the meeting at Oxford in 1894, fell on Feb 3 last It is interesting to recall that, for a great part of his life, scientific experiment was the favourite occupation of his leisure hours In the earlier phases of this hobby, his interest lay in the direction of chemistry, especially as applied to photography, in that stage of its development when the amateur had to be a good deal more independent of expert assistance than he is to day In the biography written by his daughter we are told that, in addition to the camera and tripod, "the paraphernalia of bottles and trays and red lamps and sheets of unsavoury velvet were, at this time of his life, a constant accompaniment in holiday travelling" We are also told that "his wife shared in the painful experiences familiar to relatives of self educating chemists", and that on one occasion he staggered into her presence and fell fainting at her feet, as the result of a too successful manufacture and inhalation—of chlorine. At a later period, when increased means brought more expensive apparatus within his reach, he turned from chemistry to electricity, and in his laboratory at Hatfield spent his leisure on prolonged and minute experiments, at first on problems of polarisation and magnetism, and later on certain spectroscopic phenomena On the latter he published a paper in the *Philosophical Magazine*, and in a German handbook on the subject they are mentioned as the first in point of time in which the conclusion was drawn that a gas at low temperature could emit a bright spectrum

Of Lord Salisbury's work at Hatfield an account written by his friend and helper, Prof H M'Leod, shows him "repeating, checking, analysing, with as much patience and enthusiasm as if such work had been the occupation of his life" There is no disposition on the part of his biographers to claim or to suggest that he would have attained high eminence as a

scientific worker had he adopted science rather than politics as his life work, on the contrary, he was so deficient in the instinct for external observation—to the extent of being on one occasion unable to recognise a colleague in the Cabinet when he saw him—that, as his daughter puts it, "it is difficult to believe that he could ever have acquired that power of recognising unlooked for phenomena among the accidental by products of an experiment to which so many discoveries have been due" But it is easy to understand his addiction to scientific experiment, with its promise of some definite result, as a restful contrast to the inconclusiveness and lack of finality in politics

A BILL for the Protection of Wild Birds in Scotland was introduced in the House of Commons on Jan 23, and obtained a first reading The bill repeals the present laws relating to wild birds, other than game birds, and substitutes a simplified code the essence of which is that all birds and their eggs are to be protected at all times, with a few exceptions The apparent simplicity of such a measure is sure to appeal to unthinking minds, but the principle of the bill is unscientific Equally to protect all birds is in reality to favour the stronger and more successful as against the weaker It has been forgotten that man, with his cultivation and industries, has irretrievably upset the balance of wild Nature The best he can now do is not to perpetuate this upset balance, but so to regulate numbers and species that so far as possible none should suffer unduly from his original interference It would be easy to cite cases where already overmuch protection has resulted in the increase of certain species at the expense of equally or more desirable birds The bill has other defects In some respects it is unnecessary legislation, for it protects many birds which require no protection It would make the schoolboy who takes a blackbird's egg a criminal Even more curious, while preserving intact all the laws which conserve game birds for the wealthy, it makes serious inroads against the old-established right of the ordinary man to obtain, if he can, an occasional meal on the seashore It is unlikely that such a bill will pass unchallenged at its second reading, which is put down for Feb 10

So little notice is taken by the public Press of Great Britain of the award of Nobel prizes, except the prizes for literature and peace, that the banquet given on Feb 3 by the Biochemical Society in honour of the Nobel Laureates in medicine and chemistry last year is of particular interest In Sweden the prizes are rightly regarded as of outstanding and world wide importance, and when they are presented on the anniversary of Alfred Nobel's death, the head of the State is present, and the ceremony is conducted with impressive solemnity and dignity The Swedish people show that they are proud of the great foundation with which Nobel entrusted them, and the nation delights to associate itself with the progressive thought and work of the recipients of the prizes. British Laureates find a very different atmosphere prevailing when they return to their own shores; and it is not surprising to know that this public indifference is not understood in Sweden. The banquet on Monday will, we hope, show that scientific people, at any rate, realise the high distinction conferred by the Nobel awards The three Laureates in medicine and chemistry who were present were Sir Frederick Gowland Hopkins, Prof Hans von Euler, and Prof Arthur Harden Prof C Eijkman was unfortunately unable to attend, owing to ill health

SIR CHARLES MARTIN presided at the banquet, which was largely attended, among the company being the Swedish Minister and Sir Ernest Rutherford, president of the Royal Society In proposing the toast of "The Nobel Laureates", Sir Charles Martin gave a very interesting survey of the growth of knowledge of accessory food factors from the time when Eijkman became director of the pathological laboratory at Weltevreden to the present period of marvellous activity Beri beri was then regarded as an infection, and it was Eijkman's experiments which showed that the disease was similar to a disease in fowls and due to a dietetic deficiency Turning to Sir Frederick Hopkins, the chairman hailed him as a prince of biochemists who has enriched physiology for forty years by his discoveries From his experiments with synthetic diets he was led to conclude that for nutrition certain minute quantities of hitherto unknown substances were essential, and so began our knowledge of vitamins Prof Harden's researches began with the fermentations of bacteria by accurate quantitative methods, and developed into his brilliant work on alcoholic fermentation His discoveries have brought about completely new conceptions of the chemistry of these changes Prof von Euler's explorations in the same field have been most extensive, and there is scarcely any aspect of the subject that he has not illuminated by his researches

MANY British botanists realised anew, during the British Association meeting in South Africa last year, the very interesting nature of the vegetation of South and East Africa and of Rhodesia Between November 1928 and March 1929, Dr T F Chipp, assistant director of the Royal Botanic Gardens, Kew, was travelling in the Anglo Egyptian Sudan and, as a result, presented to the Royal Geographical Society on Jan 13 an interesting account of the vegetation features of this West African botanical region Vegetation belts of very different character are found, lying at varying distances from the Gulf of Guinea and ranging from the luxuriant development of vegetation in the south west area, favoured by the monsoon from the Gulf, to the desert vegetation to the north east in an area desiccated by the north-east Trades from the continent of Asia Whilst climate, therefore, plays an all important rôle in determining the distribution of vegetation, biotic factors, as exemplified by man, may play a very important part in two ways, which seem of fundamental importance from the Cape to Cairo, namely, shifting native cultivation and the burning of the dry grass and bush lands

MAJOR CHIPP, with his experience both of vegetation and of problems of agricultural and horticultural significance, discussed one administrative problem

that deserves examination He pointed out that the political units in Africa are by no means natural vegetation units Each big British territorial unit cuts across a number of the natural belts of vegetation, and so independently, in each territory, as scientific investigation begins to precede further agricultural exploitation, the same problems are taken up afresh by different investigators at different, and very isolated, centres This would not matter if the men and money available were unlimited, but this is very far from being the case As Dr Chipp said "no one country can afford to maintain a staff of specialists sufficient to deal with all the food crops and crops of commercial importance which occur within its boundaries, and the inevitable tendency is for a few individuals in each country to attempt research into vastly different problems" Such a dissipation of our very limited available scientific resources will certainly prove wasteful Possibly, as the new tropical research centre at Amani, in Tanganyika Territory, gets into its stride, we shall see a better co ordination and utilisation of the efforts of a widely scattered body of scientific workers, whose labours should certainly be utilised to best advantage if the tropical resources of the Empire are to be tapped at a pace in any measure commensurate with our needs

THE esteem in which the late Ernst Abbe was held by his countrymen is well illustrated by the fact that, twenty five years after his death, *Die Naturwissenschaften* devotes more than half its issue of Jan 17 to an account of his connexion with the firm of Zeiss, written by Dr H Hartinger Most of the facts are already known from the "History" by Prof von Rohr, but they furnish a romance of science which still bears repetition Carl Zeiss, after learning his trade as an instrument maker at Weimar and working in Vienna, Berlin, and other towns, established himself in 1846, at the age of thirty, as instrument maker to the University of Jena His experience convinced him that great improvements in the microscope were possible, and in 1866 he took into his works Ernst Abbe, a mathematician of twenty six years of age, trained at the University and clever with his hands, and the firm began to construct instruments with Abbe's improvements When, in 1870, their progress was stopped by the want of glass with new properties, they called in Otto Schott, and with the aid of a grant of £3000 from the Government, established the Jena glass works in 1884, proceeded to make the glass required, and in this way produced their apochromatic objective in 1886 Carl Zeiss died in 1888, and his son retired in 1889, leaving Abbe the sole head of the firm Much of the work now fell on the shoulders of Abbe's assistants, Rudolph, Czapski, and von Rohr, and in 1903 he gave up scientific work He died two years later A statue of him by Hildebrandt stands in the hall of the University of Jena, and views of this and a smaller one by Hischen are reproduced in the article An indifferent photograph of Abbe in 1886, a good one of Zeiss in 1883, and a drawing of the house in which he lived in 1834–38 are also reproduced

THE regulations of the Post Office with regard to broadcast licences in Great Britain have been subjected to criticism, some of which is discussed in the *Wireless World* for Jan 29 In particular, a Post Office regulation states that "The Licensee shall not use or allow the station to be used for the receipt of messages other than messages intended for receipt thereby or sent for general reception" Listeners, therefore, who take pleasure in picking up the messages sent out from Croydon air port to aeroplanes flying between England and the Continent have a guilty feeling that they are breaking the law One of them, Mr Cyril E Baron, during the recent gales, picked up SOS calls from a ship in distress in the Channel Finding that the calls were not being answered, he communicated the information by telephone to the North Foreland Radio Station, and by this action was probably the means of saving the ship and the lives of those on board For this action, presumably illegal, he was duly thanked by the Post Office instead of having his licence cancelled The Post Office cannot hope to prevent listeners on radio receiving sets overhearing messages which it is desired to keep secret Those who are expert at the Morse code occasionally are interested in the messages they hear from ships at sea As a general principle, it is not advisable to publish regulations which cannot be enforced

LORD RAYLEIGH discussed, in his Friday evening discourse delivered at the Royal Institution on Jan 31, "Iridescent Colours in Nature" The colours of insects, said Lord Rayleigh, are of two distinct classes Some of them are due to pigmentary substances, for example, the tortoiseshell butterfly owes its red colour to pigments, and accordingly the red colour is seen by transmitted light On the other hand, blue butterflies apparently never owe their colour to a pigment, for example, in *Morpho Rhetenor*, the blue colour seen so brilliantly by reflection disappears entirely by transmitted light, a nondescript brownish colour being alone perceptible The experimental evidence leads to the view that the blue butterfly owes its colour to interference of light, the reflection at the front and back surfaces combining to give this interference for the less refrangible parts of the spectrum, and leaving the blue as a residuum The colours of metallic beetles are of special interest and have excited considerable controversy Some authorities attribute them to the surface reflection of intensely absorbing matter assumed to be present in the wing case, and in fact to be analogous to the surface reflection of aniline colour Lord Rayleigh held that this view presents insuperable difficulties First, the colour by absorption is not saturated, as it always is in the case of substances known to give surface reflection Secondly, the colour of the reflection changes greatly with the angle of incidence, while surface reflection colours do not Lastly, when the spectrum is examined by absorption, it is found that bands are present which can be identified as essentially the same over different parts of the specimen, but vary slightly in position The colour seems to be due to interference in this case also, the peculiarities of the

reflection and also of the absorption being due to the presence of a large number of reflecting layers suitably spaced

Prof J L Myres's presidential address to the Royal Anthropological Institute on "Anthropology, National and International", which was delivered at the anniversary meeting on Jan 28, was a valuable survey of the movements during the last century to promote intercourse between men of science within their own country and internationally Of these the British Association, which will celebrate its centenary next year, is a noteworthy example In the international field, anthropology appeared early with the International Congress of Archæology and Prehistoric Anthropology, which first met in 1864 and continued to meet at more or less regular intervals up to 1912 At Geneva in that year it was decided that the next session should be held in Spain in 1915 The War intervened and the meetings have never been resumed, although an attempt was made to hold a congress at Madrid in 1927, which fell through after the preliminary arrangements had been made

The present position in regard to an international congress of anthropology is one of considerable difficulty, of which the facts are admirably summarised by Prof Myres's address At the close of the War, our French allies, among their praiseworthy efforts to reinstate international co operation in intellectual affairs in accordance with the intention of the treaty of Versailles, founded an Institute of Archæology in Paris to which the title of 'International' was given One of the objects of this Institute was the promotion of international congresses in archæology and anthropology Several such congresses have been held at triennial intervals, beginning with that at Liège in 1921 But, as Prof Myres showed, whatever may have been the case in the period immediately after the War, a congress organised in conditions at present inseparable from the constitution of the French institute can no longer comply with the requirements of a congress which is truly to be regarded as international The problem, though difficult, should not be insoluble It appears essentially one for which a solution might be found through the International Research Council

The relationship between the engineer concerned with petroleum and the industry itself is not easy to define It is usually clouded by argument as to whether the engineer made the oil industry or the industry the oil engineer It is further complicated by lack of agreement as to what really constitutes the engineer in the oil industry, since according to circumstances and national custom the designation may imply anything from a raw driller's assistant to the highly trained and technically qualified consultant This would seem *prima facie* a case for a formula, but Mr John Gillespie's discursive paper on the subject at the Institution of Petroleum Technologists on Dec 10 cannot be said to have supplied one If one takes the stand at the outset that "the engineer *is* in the forefront, and forms, and will always form, the spearpoint in this line of attack upon the resources which Nature has hidden ", then obviously the engineer made the oil industry and the relationship becomes practically parental

We would remind Mr Gillespie, however, that in many instances the geologist might legitimately claim to be in the forefront of the attack on oil resources that it is due to his initial efforts that the engineer is led to the scene where his "spearpoint" will prove most effective On the other hand, there are equally cases where the engineer, either because he has no use for the geologist or because he believes more fervently in his own judgment, occupies the front line from the start The early history of development of the industry is full of examples of the triumphs of pioneers of this kind, and to them all honour is due But in latter days, oilfields are not so easily located, those that formerly were 'there for the asking', so to speak, are now worked out, and new discoveries are more and more determined by intensive technical effort, to the inevitable displacement of the old time oil engineer The vocation of the petroleum engineer to day is entirely professional and specialised, in some countries he is both geologist and civil engineer, in others, he is fundamentally the engineer responsible for winning the oil successfully from the pool, and his geology is second hand The driller is the mechanical engineer on the field he is not a geologist and never will be The matter will for long continue to be contentious, but it will scarcely be helped to settlement by exaggerated claims for one individual or the other

Sir Douglas Mawson announces further discoveries in the Enderby Land region of Antarctica in messages to the *Times* After finding that Enderby Land extends to the south west in long 46° E, he turned eastward and passed in lat 66° 22′ S, long. 48° 30′ E, the tip of a great ice shelf walled by 200 feet ice cliffs This ice shelf extends south east to join the land It is evidently comparable with the Termination and other floating ice shelves already known and is responsible for many of the large tabular bergs already reported in the neighbourhood About three degrees farther east the land faces the sea in a rocky height of 1500 feet on which antarctic petrels and other birds were nesting Several aeroplane flights have facilitated exploration The ice plateau of Enderby Land seems to rise in the interior to about 4000 feet and there are many nunataks protruding through the ice On one flight no less than 73 were visible at one time, one of them being 7000 feet in height The *Discovery* is now short of coal The Norwegian expedition in the *Norvegia* was last reported to be moving westward from Enderby Land carrying out oceanographical researches An aeroplane is being used for coast exploration and reconnaissance of ice conditions

Psittacosis or parrot fever has lately been much before the public The disease is primarily one attacking parrots and some other birds, and is contracted by close association with sick birds In man it causes a fever of a septic or typhoid like type with bronchitic or pneumonic complications, and severe cases are rare,

though milder forms may be more frequent and be mistaken for other maladies A considerable epidemic was reported in Argentina last July, and according to a *Daily Science News Bulletin* issued by Science Service, Washington, D C, 38 cases have recently occurred in the United States The disease has been attributed to infection with *Bacillus psittacosis*, a micro organism first isolated from Parisian cases by Nocard in 1893 and very similar to, or identical with, *B aertrycke* of food poisoning This organism does not appear to have been found in the recent cases investigated, and Bedson, Western, and Simpson, in the *Lancet* of Feb 1, p 235, suggest that it may prove to be a secondary infecting agent, and that the disease may be caused by a filter passing virus

MR F TWYMAN will deliver his presidential address to the Optical Society at the meeting to be held at the Imperial College of Science and Technology, South Kensington, on Thursday, Feb 13, at 7 30 P M The subject of the address is "Optics in Radio Transmission and other Fresh Fields"

SIR HAROLD HARTLEY, fellow and tutor of Balliol College, Oxford, and distinguished for his work in physical chemistry, has been appointed a vice president of the London, Midland and Scottish Railway Co in succession to the late Mr R W Reid, and also director of scientific research to the Company

LIEUT COLONEL THE RIGHT HON WALTER E GUINNESS, M P, has been elected president of the Marine Biological Association of the United Kingdom in succession to the late Sir E Ray Lankester Colonel Guinness was Minister of Agriculture and Fisheries in the recent Conservative Government

MR A H G ALSTON has been appointed Assistant Keeper in the Department of Botany, British Museum (Natural History), where he will be in charge of Pteridophytes Mr Alston was formerly systematic botanist to the Department of Agriculture, Royal Botanic Gardens, Peradeniya, Ceylon

MR G S GORDON, president of Magdalen College, Oxford, Prof O W Richardson, director of research in physics, King's College, London, and Mr H T Tizard, Rector of the Imperial College of Science and Technology, have been elected members of the Athenæum Club under the provisions of the rule which empowers the annual election by the committee of a certain number of persons of distinguished eminence in science, literature, the arts, or for public service

IT is announced in *Science* that the Edison medal, awarded by the American Institute of Electrical Engineers for "meritorious achievement in electrical science, electrical engineering, or the electrical arts", has been conferred on Dr Charles F Scott, professor of electrical engineering at Yale University, who was president of the Institute so long ago as 1902, for "his contributions to the science and art of polyphase transmission of electrical energy"

THE council of the Institution of Naval Architects has awarded the Gold Medal for the year 1929 to Mr John Johnson, chief superintendent engineer of the Canadian Pacific Steamship Line, for his paper "The Propulsion of Ships by Modern Steam Machinery", and the Premium to Lieut Col F Dondona, for his paper "Sea Trials of Italian Destroyers" The medal and the premium will be presented at the opening of the annual general meeting, which will be held on April 9 at the Royal Society of Arts, John Street, W C 2

APPLICATIONS for the Government grant for scientific investigations must be made upon forms obtainable from the Clerk to the Government Grant Committee, Royal Society, Burlington House, W 1, and returned not later than Mar 31

THE annual general meeting of the Institute of Metals will be held in the Hall of the Institution of Mechanical Engineers on Mar 12 and 13 The president is Dr W Rosenhain, and the president designate, Dr R Seligman In addition to the reading and discussion of papers, members will be given facilities for visiting the Birmingham section of the British Industries Fair The May lecture of the Institute will be delivered on May 7 by Dr F A Freeth, joint research manager of Imperial Chemical Industries, Ltd

THE annual meeting of the Iron and Steel Institute will be held at the house of the Institution of Civil Engineers, Great George Street, London, S W 1, on May 1 and 2, under the presidency of Prof H Louis The autumn meeting this year is to be at Prague during the week beginning Sept 15, in response to an invitation from the Society of Czechoslovakian Engineers, in the house of which the meeting will be held As arranged in 1928, the autumn meeting for 1932 will be held in the United States, at the invitation of the American Iron and Steel Institute and the American Institute of Mining and Metallurgical Engineers

THE provisional figures of the birth and death rates and infant mortality for England and Wales during 1929 have been issued by the Registrar General The birth rate, 16 3 per 1000 population, is the lowest recorded, and is 0 4 below that of 1928 The death rate is 13 4 per 1000 population, which is 1 7 above that of 1928 The rise is practically confined to the first quarter of the year, and is due to the prevalence of epidemic influenza and to the severe weather in that period The same causes probably account for a rise in the infant mortality rate (deaths of infants less than 1 year of age per 1000 live births) from 65 in 1928 to 74 in 1929

THURSDAY last, Feb 6, was the centenary of Daniel Oliver, for many years Keeper of the Herbarium at Kew, and also professor of botany at University College, London He was born on Feb 6, 1830, at Newcastle on Tyne His work at Kew began in 1858 he retired from the Herbarium in 1890 and died in 1916 at Kew His official life was entirely devoted to his botanical work, and he was gifted with remarkable insight and a great habit of accuracy Oliver's unofficial life was largely given to art He worked in sepia, chalk, oil, and water colour It is proposed to hold an exhibition of his drawings at Kew this summer, the Director of the Royal Botanic Gardens has arranged for the show to be held in one of the

museums at Kew It is thought that this by-product of the life of a serious botanist may be of interest to both artists and scientific workers The works are of varied character and many are of great delicacy

THE recently issued catalogue (No 448) of Messrs Bowes and Bowes, Cambridge, contains the titles of upwards of 3000 works relating mainly to mathematics, astronomy, and physics It is of special interest because most of the volumes belonged to such distinguished men as the late Dr J W L Glaisher, James Glaisher, Prof G H Bryan, and Dr R A Herman The prices asked appear to be reasonable The catalogue can be obtained upon request

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —An assistant lecturer in biology in the Department of Education of the University College of the South West, Exeter—The Registrar, University College, Exeter (Feb 15) An instructor in commercial fruit growing and an assistant agriculturist under the Kent Education Committee—The Agricultural Organiser, Springfield, Maidstone (Feb 20) A part time master for mathematics at Willesden Polytechnic School of Building—The Principal, Willesden Polytechnic, Kilburn, N W 6 (Feb 22) Two appointments in the Forest Service of Burma—The Secretary to the High Commissioner for India, General Department, 42 Grosvenor Gardens, S W 1 (Feb 24) A demonstrator in the Division of Bacteriology and Immunology of the London School of Hygiene and Tropical Medicine—The Secretary of the London School of Hygiene and Tropical Medicine, Keppel Street, W C 1 (Feb 24) Three research assistants in the Department of Coal Gas and Fuel Industries of the University of Leeds—The Registrar, The University, Leeds (Feb 24) A lecturer in chemistry and a lecturer in mathematics at Raffles College, Singapore —The Private Secretary (Appointments), Colonial Office, 2 Richmond Terrace, Whitehall, S W 1 (Feb 28) A histological assistant under the Joint Board of Research for Mental Disease, Birmingham—The Director, Joint Board of Research for Mental Disease, City and University of Birmingham, Hollymoor, Northfield, Birmingham (Mar 1) An advisory veterinary officer at the Seale Hayne Agricultural College — The Principal, Seale Hayne Agricultural College, Newton Abbot, Devon (Mar 1) A professor of pathology and bacteriology in the Veterinary College, Patna—The Secretary to the High Commissioner for India, General Department, 42 Grosvenor Gardens, S W 1 (Mar 15) An experimental assistant at the Air Defence Experimental Establishment — The Superintendent Air Defence Experimental Establishment, Biggin Hill, near Westerham, Kent A technical officer in the Admiralty Technical Pool for service in an Admiralty Establishment at Portsmouth—The Secretary of the Admiralty (C E Branch), Whitehall, S W 1 Three research assistants under the British Cotton Research Association—Dr R H Pickard, Shirley Institute, Didsbury, Manchester A veterinary advisory officer in the Department of Agriculture and Horticulture of the University of Bristol—The Secretary, The University, Bristol

Our Astronomical Column

Comets —*Popular Astronomy* for January contains an enlargement (six times) of a photograph of Wilk's comet taken by Prof G van Biesbroeck at Yerkes Observatory on Dec 22 The exposure was for 20 minutes, the coma appears exactly circular, 20′ in diameter, its brightness is nearly uniform, but there is a slight fading at the edges A central condensation could be seen visually, but does not appear in the reproduction It is noted that a slender tail, pointing almost exactly opposite to the direction of the sun, can be traced through 20′ on the negative Prof van Biesbroeck also gives reproductions of the two plates taken by M Quénisset in Switzerland of Forbes's first comet on Oct 25, 1928, nearly a month before its discovery Prof van Biesbroeck has measured the enlargement of the first plate, and gives the following position of the comet, which he estimates to be trustworthy within 5″ 1928 Oct 25 1542 U T, R A $10^h\ 56^m\ 54\ 5^s$, N Decl 11° 32′ 3″ (equinox 1928 0)

The Central Solar Eclipse of April 28 next —This eclipse will be total for about 1½ seconds in the western parts of the United States of America It passes a little north of San Francisco and runs from there in a north easterly direction *Popular Astronomy* for January states that the Lick Observatory is sending an expedition to Camptonville, California, under Dr Moore its work will be mainly spectrographic, and Dr Menzel will try to photograph the flash spectrum Dr Aitken states that an attempt will also be made to obtain at least one photograph of the corona three observers with cameras will be stationed at intervals of ¼ of a mile along a line at right angles to the central line, as there is inevitable uncertainty of at least this amount in the prediction of that line This is one of the eclipses that, though 'invisible at Greenwich', is visible in portions of the British Isles A small partial eclipse will be visible before sunset over the whole of Ireland and the northern part of Scotland

The Grootfontein Meteor —*Popular Astronomy* for January contains an account of this enormous meteor by Dr W J Luyten, who made the long journey (1550 miles) from Bloemfontein to Grootfontein in order to study it Several photographs of the meteor are reproduced It is roughly rectangular in shape, about 10 ft by 9 ft, and the thickness at the sides varies from 2½ ft to 4 ft Analysis of portions of it indicates that it is about one sixth nickel, the rest nearly pure iron Its specific gravity may be estimated as 7 3, and its mean thickness as 3 2 ft its mass in tons would then be roughly 58 7 tons it cannot be much less than this, but may be more if there is a 'nose' in the middle of the base It is probably the most massive meteor known, that brought by Peary from Greenland weighed 36 5 tons Dr Luyten, who removed a small fragment, noted that it was as hard as the hardest steel He states that the existence of the meteor has been known in the neighbourhood for "a considerable length of time", but no record of the date of fall is mentioned He also mentions a valley "east of Gibeon" that contains a number of smaller meteors, weighing about 500 lb each, but these have been known for a long time They contain less nickel than the great meteor —only 7 or 8 per cent

Research Items

Plant Remains in Sun-dried Bricks—Prof George W Hendry, of the University of California, looking for the source of the black oats grown in Sonoma County, California, noticed that adobe bricks contain well preserved specimens of vegetation Since that time, 14 sun dried brick buildings in different parts of California have been examined, and whilst not one sprig of black oats has been found, many interesting data have been obtained as to plant introductions and were reported by Prof Hendry at the meeting of the American Association for the Advancement of Science at Des Moines in December last (*Daily Science News Bulletin*, Science Service) The approximate dates of introduction and sources of many plants and weeds, however, have been accurately determined from a careful study of the ages of the buildings in which they occur In spite of the fact that much of this vegetation has been embedded in the clay for more than a century and a half, it is still preserved well enough for identification Contrary to popular belief, it has been definitely established from these finds that wheat was introduced into California during the Spanish period Barley has been found in 12 of the 14 missions examined, which shows that its culture lasted from 1701 to 1837 Only one kernel of wild oats has been discovered, and that was taken from the pulpit stair of the old church of the Mission of San Juan Bautista It is thought that the present wide dissemination of wild oats in California has occurred since 1837 Remains of garden crops, ornamental plants, fruits and fibre plants taken from the sun made bricks have also been identified

The Gaits of Quadrupeds—Having already analysed in a lengthy and detailed monograph the motions and limb stances of galloping animals, P Mayne de la Croix has now turned his attention to the elucidation of the laws which he thinks rule the evolution of locomotion in the vertebrates (*Anal Soc Cient Argentina*, t 108, p 383, 1929) A long series of observations leads him to postulate the great law of the evolution of quadrupedal locomotion as follows Progression takes place from the alternate use of quadrupedal and tripedal stances to the sole use of unipedal stances, and this evolution is made possible by means of a discord, always increasing, between the period of the swing of the anterior and that of the posterior Further, he finds that, just as in rapid gaits times of suspension are intercalated, when the animal is entirely free from the ground, so in slow gaits there are intercalated times of 'arrest' when the animal reposes upon all fours By this means are distinguished four great groups of gaits—reptilian creeping gaits, reptilian leaping gaits, walking gaits, and leaping gaits—and the author proceeds, aided by a series of figures of the successive poses in these types of movement, to trace what he calls the phylogeny of locomotion

Habits of the Manx Shearwater—Much acute field observation makes R M Lockley's account of the breeding habits of the Manx shearwater (*Puffinus puffinus*) of special interest (*British Birds*, vol 23, 202, 1930) The birds were studied upon Skokholm, a rock bound isle off the coast of Pembrokeshire, where some five thousand pairs breed Nesting burrows having been marked and traced to their end, a large sod was very carefully cut immediately over the nest, so that, when need be, this improvised window could be opened for observation Although shearwaters are nocturnal birds, spending the day in the farthest recesses of their burrows, it was found that while the nesting holes were visited nightly with great regularity, during the day one or both of the paired birds might be absent Both parents incubate the eggs, but one bird may sit for several days at a stretch, its only exercise being the turning of the solitary egg Probably during this period it is fed by its mate The passage of the young birds from the nest to the sea is attended by considerable mortality Most of the young at this stage still bear some of the down plumage, and since they are unable to rise on the wing except in face of a stiff breeze, they make an awkward and exhausting journey on foot across country if the weather be calm Should daylight find them still in the open, gulls and other marauders almost certainly destroy them The young which reach the cliff edge launch themselves straightway into the air, and flap downwards to the dark sea

Evolution of the Pelvis of Primates—Miss H C Waterman (*Bull Amer Mus Nat Hist*, vol 58, pp 585 642, 1929) has made a detailed study of the pelvic region of thirteen genera of Primates, with the purpose of determining the relation between the loco motor habits of the animal and the external form of the pelvis It was hoped thus to provide material of value in the attempt to separate habitus from heritage characters in these forms and to obtain some light on the evolution of the pelvis within the group The results of her studies lead Miss Waterman to support Gregory's views as to the main stages in the evolution of the pelvis from primitive arboreal quadrupeds to man These stages are (1) a primitive lemuroid stage, (2) the stage of the primitive monkey in which there are incipient adaptations for upright sitting, (3) the stage of the quadrupedal monkey in which adaptations for upright sitting are perfected, (4) the brachiating stage, and (5) the stage of bipedal man

Solution of Coral Reef Limestone—In the *Geographical Journal* for January, Mr W A Macfadyen describes the result of some of his observations on coral islands in the Red Sea His work was done on the Ashrafi and Jubal Islands at the mouth of the Gulf of Suez and on the Farsan Islands and Kamaran Island in the south east of the Red Sea These are practically all islands of reef limestone fringed with growing corals They project above a submerged platform and are fringed with shallow water which largely protects the coast from erosion by wave action The coasts are usually fringed by undercut cliffs The undercut may reach a depth of three or four feet The sharpened and roughened surface of the undercut suggests solution rather than wave action, which would give a smooth surface The presence of barnacles on miniature pedestals also suggests solution At the same time, Mr Macfadyen admits that boring and other organisms probably play some part in the formation of the undercut cliffs The small range of the tide confines action to a narrow depth and makes it more conspicuous

Physico-Chemical Phenomena in the Silkworm's Egg—The results of an investigation of the various chemical and physico chemical phenomena observed in the egg of *Bombyx mori* are described by Dr Mario Tirelli in the *Atti della Pontificia Accademia delle Scienze* (*Nuovi Lincei*) for 1929 It appears that the silkworm's egg is the seat not only of a morphological, but also of chemical and physico-chemical ontogenesis, which is to some extent independent of the first Embryonal development is accompanied by characteristic variations in the viscosity, cryoscopic

point, and amino acid content of the egg, which contains a proteolytic enzyme The liquid of the egg exhibits the power of undergoing stratification, which takes place in different manner with different strains and may be easily reproduced by adding toluene to the liquid and drawing the latter up into tubes The viscosity of the egg is characteristic of the race and, in the case of crosses, is sometimes intermediate to the values for the parental races, so that the male element also exerts an influence in modifying the physico chemical characters, and hence the chemism, of the egg

Studies on Tetrarhynchids —Descriptions of larvæ of *Tetrarhynchus* deal for the most part with external features and systematic characters The late Dr H Cammerloher (*Sitzungsber Akad Wiss Wien*, Mat nat Kl, 138 Bd, pp 125 143, 1929) describes the structure of the larva of *Anthocephalus elongatus* from cysts on the liver of *Orthagoriscus mola* All the specimens, which were obtained at Trieste, Naples, and Messina, had completely formed proboscides, younger stages were not found In the fresh liver the worms lie motionless in their cysts, but when the cyst is dissected in sea water, active rhythmic movements of the larva are observed which are also seen in specimens in the liver when the latter begins to decompose Larvæ preserved in extended condition are about 25 mm long After a brief account of the larva as seen in a whole mount, the author describes transverse sections through three different regions of the body and one through the tail appendage One of the most interesting points in the histology is that giant fibres are present in two of the nerves, seen in transverse section of the bothridial region, which innervate the muscle bases of the proboscides The muscle in the parenchyma in relation to the proboscides exhibits a spiral striation In the following paper Dr T Pintner describes the original example of *Diesingium (Rhynchobothrium) lomentaceum* Diesing, 1850, preserved in the State Museum in Vienna, from *Mustelus* taken at Palermo

Hyperfine Structure in Line Spectra —It is by now well established that there is a hyperfine structure to certain spectral lines which requires for its description an additional quantum number, and that the effect has its origin in the rotation of the nucleus The nature of the information which can be obtained from a study of this effect is well illustrated by two papers by H E White in the first December issue of the *Physical Review* The first of these deals with the spectrum of singly ionised praseodymium, data being given for the structure of 173 lines, all of which have six components spread over an interval of only about a quarter of an Ångström unit High spectral resolution is naturally needed to bring out such detail, and has been obtained in this instance by working in the fourth order of the 75-ft grating spectrograph at Mt Wilson, reproductions of the photographs obtained for ten typical lines are shown The praseodymium nucleus has been shown to possess an angular momentum of $\frac{5}{2}$ Bohr units, which compounds with the angular momentum of the outer electrons of the ion according to the usual rules of the quantum theory The second paper treats of the theory of the effect at greater length, with particular reference to the spectra of cadmium, bismuth, and lanthanum, and it is stated in a note that the theories advanced also fit in well with the structure reported by Prof McLennan and his collaborators for the spectrum of ionised thallium (Tl II), and with the author's own preliminary observations with manganese The same issue of the *Physical Review* contains a letter from S Goudsmit and R F Bacher on the subject of the Paschen Bach magnetic effect with hyperfine structure

Quenched Arc Switches —The large currents and the very high voltages now used in the networks distributing electrical energy have greatly increased the difficulty of breaking the supply in the event of a fault developing in a section of the network The problem of constructing an oil switch which breaks the current under oil has been solved up to a rupturing capacity (the product of the open circuit volts at the break and the short circuit current) of 800,000 kilo volt amperes When the switch contacts separate under the oil a high temperature arc ensues and a gas bubble is formed which rapidly increases in size even after the arc is extinguished In a medium sized switch the bubble may grow to be a foot in diameter and the gaseous pressure even when a large air chamber is provided may rise to 200 lb per square inch The energy evolved in a break depends on so many variables that it is impossible to predict accurately what will happen In a paper read to the Institution of Electrical Engineers on Jan 23 by L C Grant, the breaking performance of high power switchgear is discussed and a new form of quenched arc switch is described He quotes interesting results on the effects produced by oil switches which have one, two, or four breaks within them He concludes that the average 'distress' produced by the three kinds of switches are in the ratio of 100 62 50 With six breaks there seems to be only a slight improvement on the four break The size of the contact pieces and the speed with which they separate have a great influence on the performance of the switch The author insists on the necessity of manufacturers having high power available to test their switches A new quenched arc circuit breaker which he described measures six inches in diameter and six inches long and weighs only 28 lb, and yet it easily broke 50,000 kilovolt amperes at 6000 volts He stated that a device of this type could be constructed to break three million kilovolt amperes

Promoter Action —It is well known that the activities of many catalysts are enhanced by the addition of small amounts of other substances, called promoters In a study of the catalytic oxidation of methane with steam (*Bulletin of the Chemical Society of Japan*, October), Kuboto and Yamanaka have observed a relation between the type of reaction and the properties of the promoters They suppose that the reaction takes place successively in the following manner

$$CH_4 \xrightarrow{H_2O} CO + 3H_2 \xrightarrow{H_2O} CO_2 + 4H_2$$

The catalyst was nickel, and it was found that the largest quantity of carbon dioxide was obtained by using a catalyst promoted by Al_2O_3, whilst when water vapour was regulated the catalyst promoted with MgO gave the largest yield of carbon monoxide The effect of the promoters may be to transfer water molecules to the reaction centres of the catalyst where the action of water on methane is occurring, and the products will then be determined according to the capacity of the promoter to adsorb water molecules and also to the size of the promoter molecules The results are in good agreement with this hypothesis in the special form given to it by Balandin in a recent communication The reactions are assumed to occur in associations of reacting molecules called multiplets, and the two factors mentioned then come into consideration

Electrical Breakdown in a Solid Dielectric

IT is now well known that if we have two spherical electrodes in a gas, then in certain cases, over a very wide range of the distance between them, the disruptive voltage can be determined with great accuracy In computing this voltage, it is necessary to know first the nature of the gas and its temperature and pressure, secondly, the radii of the electrodes and the distance between them, and thirdly, the electric strength of the gas

The only problem that is laborious and difficult is the computation of the maximum electric stress between the electrodes When the electrodes are equal, these values can be found from tables well known to electrical engineers For example, when the electrodes are each one inch in diameter, the disruptive voltage in air can be computed with at least a one per cent accuracy at distances varying from one tenth of an inch to three inches, the corresponding voltages varying from about 10,000 volts to 50,000 volts When the spheres are closer together than a tenth of an inch, other physical factors have to be taken into account Everyday experience seems to show that there is a minimum sparking potential which is about 350 volts in air at ordinary atmospheric pressure and temperature

The early experimenters, only having a few thousand volts available, were naturally unable to find any simple law connecting sparking voltage and distance Kelvin, however, in his Reprint of Papers, pointed out so far back as 1860 that if we regarded the maximum electric stress as the determining factor, then it was 'most probable' that the numbers obtained in this way at higher voltages would be found to be sensibly constant, a surmise which has been rigorously proved in recent years by electricians

With electrodes in a gas, there are three cases which need to be considered separately First, when they are very close together, secondly, for distances apart up to about three diameters of either electrode, and thirdly, for greater distances when coronæ form before the breakdown discharge occurs It is very easy to calculate in the last case when the corona appears

In the *Journal of the Franklin Institute* for December, P H Moon and A S Norcross prove that in a solid dielectric there seem to be three different physical causes that lead to its disruption by electric stress The experiments were made on the lead glass of the approximately spherical bulbs of flasks Mercury inside the flask formed one electrode, and it was immersed in a bath of mercury which forms the other electrode This arrangement gets rid of the edge effect All the tests were made with direct current voltage obtained either from a hundred kilovolt kenotron set or a 4000 volt motor generator set

It was found, first, that for low temperatures and for low values of the thickness, the relation connecting the breakdown voltage with the thickness of the glass is a linear one Secondly, for higher temperatures and greater thicknesses, the breakdown voltage is no longer independent of the temperature but decreases as the temperature is raised Finally, when the temperature is raised above 150° C, the effect of temperature becomes much more pronounced and we reach the region of thermal instability which has been much studied by electricians Tests with sodium lime glass give similar results Apparently there is no connexion between resistivity and breakdown in the disruptive region Messrs Moon and Norcross consider that there are three distinct mechanisms of breakdown, the one that actually takes place depending on the temperature, thickness, and constants of the material

Transport of Stones by Attached Seaweed

MR SYMINGTON GRIEVE directed attention to the ocean transport of stones through the buoyancy of attached seaweed, with their consequent piling up as a stony beach where obstacles intercepted the ocean currents, in a paper in the *Transactions of the Botanical Society of Edinburgh*, vol 14, pt 2 (1882) This paper is reprinted in the *Trans and Proc Bot Soc*, vol 30, Part 2, 1929, together with further papers which give results of additional observations by the author since that time Charles Darwin discusses in "The Voyage of the *Beagle*" the transport of stones to Keeling Island and other atolls, through their attachment in the roots of floating trees, and it is interesting to learn that shortly before his death (Mar 22, 1882) he wrote to Mr Symington Grieve from Down a brief note that indicated his interest in the subject, in which he states that he had "long known that stones were transported by floating Fuci"

Probably almost every naturalist who reads these interesting papers will recall some observation from his own experience which might have enlightened him as to the buoyancy added to stones by the canopy of attached seaweed, but it has been left to the author to realise the significance such an apparently incidental occurrence may have, both in building up beaches of water worn rocks, in contributing to the erosion of the cliff surface by its bombardment by *Fucus* transported missiles in the waves, and even in contributing to the dislodging of massive masonry exposed to the waves and which, in time, has become covered with a canopy of seaweed Around the British Isles the seaweeds that contribute most in giving buoyancy to the stones on which they grow are *Fucus vesiculosus* and *Fucus (Ascophyllum) nodosus*, to a lesser extent *Fucus serratus* and *Chorda filum*

The author points out that the shape of the stone and the extent of the surface it exposes for the growth of the seaweed will be factors of importance in determining whether it is lifted from its bed by the tide, as also will be the amount of growth of the seaweed and the height of the water above it when under the influence of this tidal scour He has noted stones with seaweed attachment drifting along the bottom of the tide, so that the stones left a grooved trail on the bottom In the earlier paper it was pointed out how such a trail may be left on the sand or mud as the tide recedes, an alternative suggestion thus arising for some of the 'reptilian marks' or 'ripple marks' described for ancient or modern beaches

The author also raises the question as to whether the sargasso seaweed, composed of the two species *Sargassum vulgare* and *S bacciferum*, as it floats away from its breeding places upon the shores of the islands of Martinique, Guadeloupe, and Dominica, may not carry with it stones on its journey in the Caribbean Sea or the Atlantic or Pacific Oceans The late Prof James Chilton directed attention, in the *Transactions of the New Zealand Institute* (vol 56, pp 523 524), to the habit of the free swimming larvæ of an ascidian of attaching themselves to pebbles, which are thus lifted from gravel beds so that, in stormy weather, they are thrown up on the beach

Developments of Electrodeposition.

THE Electroplaters' and Depositors' Technical Society held its annual convention on Jan 31 at the Northampton Polytechnic Institute, St John Street, Clerkenwell, one of the features of the meeting being an exhibition representative of modern scientific and practical advances in electrodeposition This may be claimed to be the first exhibition devoted purely to the interests of the many phases of electro deposition ever held in Great Britain and is indicative of the big strides which have occurred in the technical development and the resultant commercial applica tions of the deposition of metals since the War The exhibition aroused great interest, and the subsequent meetings were attended by members and visitors from all parts of the country

The afternoon meeting was addressed by Dr W Rosenhain, of the National Physical Laboratory, Teddington, who discoursed upon "Research and Practice" In the evening, a discussion was held on the "Present Position of Chromium Plating", at which more than two hundred people were present, Dr R S Hutton, director of the British Non Ferrous Metals Research Association and president of the Electroplaters' and Depositors' Technical Society, being in the chair The discussion dealt with the practical aspects of chromium deposition

The exhibition was fully representative of practi cally every phase of the science and art of electro deposition Exhibits illustrated the application of electroplating for decorative (as in nickel and chromium deposition) and protective effect (as in the deposition of cadmium and zinc on ferrous metals), the 'building up' of worn parts by depositing iron or nickel and grinding afterwards to the required size, electrotyping and galvanoplasty, deposits being shown upon such non conductors as glass, porcelain, plaster, vulcanite, and cellulose acetate

One of the most remarkable exhibits consisted of very thin gold and nickel films, prepared by Dr Carl Muller of the Physikalisch Technisches Reichsanstalt, Charlottenburg, Berlin These gold films are 60 mm in diameter, and, although transparent, quite non porous The thickness of the films is no more than 0 00002 mm One of the applications of these films is for use as windows for cathode ray tubes, for which purpose they are supported on grids It is interest ing to add that Dr Müller has exhibited elsewhere similar electrolytic films, ranging from 0 00002 mm up to 0 001 mm in thickness, in both a polished and matt condition In one of these exhibits the trans parency of these films was illustrated in a striking way, printed type being distinctly read through six foils placed one behind the other The Royal Aircraft Establishment, Farnborough, at the same time exhibited films of aluminium oxide obtained in the anodic oxidation process which are of the order of one eighty thousandth of an inch in thick ness

Among the comprehensive exhibits of the Research Department of the Woolwich Arsenal, X ray spectra of deposited nickel were shown, indicating in striking fashion the difference between hard and soft nickel deposits The soft deposit is build up of nickel crystals, nearly all of which have their cube faces nearly parallel to the plane of the deposit, but have a random orientation about the direction of the current The hard deposit is built up mainly of a random arrangement of nickel crystals, but there is an appreciable number of crystals with their dodeca hedral planes parallel to the plane of the deposit, thus giving a weak symmetrical pattern in the perpendicular spectrum

Native Fish-Poisons as Insecticides.

THE use of certain orders of plants for purposes of stupefying and catching fish is almost world-wide, this practice in countries under British control is now deprecated and in many cases prohibited There are references to this custom scattered through-out the literature of exploration, and in the course of time a considerable list of the plants used has been compiled

Derris or tuba root (*Deguelia elliptica*) of the East Indies is the most widely known of these plants owing to its increasing use as an insecticide An examina tion at the Rothamsted Experimental Station of derris and many other tropical fish poisons, collected by Empire officers, indicated that for insecticidal purposes those of the order Leguminosæ were, in general, the most potent Among those of a high order of toxicity are two plants used by the Indians of British Guiana and known to them as white and black haiari (*Lonchocarpus* spp), which contain the characteristic principle of derris root—now known as rotenone—a most potent insecticide These plants, which are lianes, have been collected in the forests of British Guiana by Mr R A Altson, but such is their habit of growth that the definite species has not been so far recognised An attempt is now being made to cultivate the haiari plants for commercial use as insect sprays and animal dips, and the Empire Marketing Board has made a grant for an investigation at an agricultural experimental station in British Guiana In the meanwhile, it is hoped that the woods and forests of British Guiana will not be denuded of plants of such prospective value

Other Leguminosæ of interest, from the fact that they possess both fish poisoning and insecticidal properties, are yarraconalli (*Tephrosia toxicaria*) of British Guiana and iLozane (*Tephrosia macropoda*) from South Africa The fact, however, that *Cocculus Indicus* (*Menispermaceæ*) possesses the same dual properties would indicate that they are not entirely limited to leguminous plants The constitution of the active principles, which are neither alkaloids nor glucosides, is unknown, although much useful research on rotenone has been in progress for several years They are possibly closely related compounds, and should well repay investigation In addition, there is much to be done to clear up the confusion of the identification of the plants arising out of the use of native names The encouragement of the Empire Marketing Board may well lead to a wider use and more extended knowledge of these interesting plants

Sea Trout from the Moray Firth

THE Scottish sea trout is a creature of much more variable habit than the Scottish salmon Mr G Herbert Nall has shown that it is a plastic species capable of adapting itself readily to its environment and reflecting in a marked degree the feeding possi-bilities of the area which it inhabits (*Fisheries, Scotland, Salmon Fish*, 1929, No 111)

The south westerly area of the Moray Firth, com-prising the Inverness Firth and the Beauly Firth, is an extensive sheet of somewhat shallow water It forms a rich feeding ground for the sea trout of the Ness and Beauly and a few minor streams Many of the fish feed most actively and grow most rapidly in summer But in mid winter, shoals of sprats and small herrings enter the firths and a large portion of the trout feed heavily upon them, and in spite of lower temperature have a period of maximum growth and fatness between

November and February Moreover, the scales of certain fish reveal on examination strong evidence that individuals may be winter feeders one year and summer feeders the next Thus, the trout of the district seem to be in a transitional stage of partial adaptation to their special environment

Between January 1921 and January 1924, nearly sixteen hundred sea trout, brown trout, and parr were marked in the Beauly Firth and in the lower reaches of the Beauly and Ness Rivers in order to glean information regarding their migratory movements About 16 per cent of these have been recaptured, the recaptures proving that there is a constant movement and interchange of fish through the firth between the tidal reaches of the two rivers As only three marked fish have been recaptured outside the firths, there is little direct evidence that the Beauly Ness fish travel far from their rivers It is scarcely likely, however, that their movements are confined to this area, since from other districts there is abundant evidence that both finnock and adult trout undertake extensive coastal migrations, and that adult trout are caught at times far out at sea

Careful study of the scales of these sixteen hundred fish has also been carried out The reversal of the ordinary seasons of growth and rest render inadequate the usual methods of scale interpretation, and special methods had to be adopted to overcome this difficulty Like most sea coast trout, the Beauly Ness fish have short lives, and few survive to spawn more than two or three times One exceptional fish, however, was in its eleventh winter and had spawned seven times

University and Educational Intelligence

CAMBRIDGE —Dr A B Appleton, University lecturer in anatomy, has been elected to a fellowship at Downing College

Mr J C Dobbie, of Trinity College, has been appointed first junior observer at the Solar Physics Observatory

Dr H McCombie and Mr H Thirkill have been appointed members of the council of the School of Physical Sciences, and Dr E K Rideal and Prof Engledow members of the council of the School of Biological Sciences

EDINBURGH —On the recommendation of the University Athletics Committee, the University Court has appointed Colonel Ronald B Campbell as director under the scheme for the promotion of the physical welfare of students and the development of University athletics, the appointment to date as from May 1

LONDON —The following doctorates have been conferred D Sc in chemistry on Mr R P Linstead (Imperial College—Royal College of Science), for a thesis entitled "Three Carbon Tautomerism", D Sc in the history, methods, and principles of Science on Mr J H Woodger, University reader in biology, for a thesis entitled "Biological Principles", D Sc in zoology on Mr E A Spaul (Birkbeck College), for a thesis entitled "On the Activity of the Anterior Lobe Pituitary"

THE examinations for the award of scholarships in engineering, science, domestic science, and hygiene at the Battersea Polytechnic will be held on Wednesday, June 11, and succeeding days The scholarships vary in value from £20 to £30 per annum with free tuition, and are tenable for two or three years The latest day for applications is April 19 Full particulars may be obtained from the Principal

Two Theresa Seessel research fellowships for the promotion of original research in biological studies are being offered by Yale University The value of each is 1500 dollars Applications, accompanied by reprints of scientific publications, letters of recommendation, and a statement of the particular problem which the candidate expects to investigate, should be made to the Dean of the Graduate School New Haven, Conn, U S A, before Mar 1 next

THE Board of Education is again prepared to receive applications for full time studentships from teachers of five years' standing who desire financial assistance in order to attend approved full time courses of advanced study at universities or other institutions at home or abroad The amount of grant will not exceed £100 for an academic year The course proposed if academic, should be of at least post graduate type, but the Board is prepared to consider also proposals involving travel or the practical study of industrial conditions connected with the teaching of technical subjects Further information and application forms, to be returned by May 31, can be obtained from the Board of Education, Whitehall, London, S W 1

THE Cecil Peace Prize, of the value of £100, is offered yearly for an essay on some subject connected with the maintenance of international peace, and having some bearing on the principles or work of the League of Nations It is open to students of any university or university college in Great Britain or Northern Ireland who have not attained the age of twenty five years on the last day for submitting essays The subject for the year 1930 is 'Possible Developments of the Economic Activities of the League of Nations" The essay must be sent in to the Secretary, Universities Bureau of the British Empire, 50 Russell Square, London, W C 1, so as to arrive on or before Nov 1 next

FELLOWSHIPS and scholarships for advanced work in science and technology are listed in a bulletin (154 pages) recently published by the National Research Council of the National Academy of Sciences, Washington The number, variety, and value of these aids and encouragements are impressive A significant feature of the situation is the important part played by industrial firms and trade associations Eighty five such bodies support fellowships or scholarships Conspicuous among these is the E I du Pont de Nemours of Wilmington, which maintains 24 fellowships, each worth 750 1000 dollars, and four scholarships of 300 400 dollars The company selects each year the institutions in which the work is to be carried on The National Canners Association, on the other hand, which grants annually 19,000 dollars for research work in connexion with the wholesomeness and nutritive value of food, leaves the disposal of the grant entirely to the University of California, which uses it in large part for the payment of salaries of assistants and fellows who conduct the work under the direction of members of the faculty Among the methods employed by the Mellon Institute of Industrial Research, Pittsburgh, is a system of 'multiple fellowships', in which the services of one or more researchers are utilised under the direction of a senior fellow who, in turn, is responsible to the executive staff of the Institute These twenty one fellowships are financed from foundation sums covering all expenses of the specific researches for which they are given, including salaries, and ranging from 8000 dollars to 80,000 dollars While the activity of industrial firms in fostering research tends to the exaltation of applied science at the expense of pure science, the latter is of course not neglected in the allocation of funds in universities Under the head of astronomy, for example, twelve fellowships are mentioned, under mathematics, twenty six

Historic Natural Events.

Feb 9, 1913 Group of Meteors—A remarkable group of meteors was observed over Saskatchewan in Canada at 9 5 P M and was last seen from ships beyond Bermuda It travelled across Canada in seven minutes and probably struck the sea after a total path of 6000 miles, traversed at from 5 to 10 miles per second The whole group consisted of at least ten smaller groups, each containing 20 to 40 meteors, which kept perfect formation while the groups followed one after another along the same path, the whole taking more than three minutes to pass a given place The groups left long trails and were accompanied by a noise like distant thunder, and in some localities the earth vibrated, but only the leading meteor of the procession burst

Feb 10, 1236 Floods—Rain continued all through January, February, and a great part of March, and for eight days it rained almost without ceasing On Feb 10, immediately after the change of the moon, there was such a high tide in the Thames that boats might have been rowed up and down in Westminster Hall

Feb 11, 1895 Great Frost—The frost of 1895 lasted from Dec 30, 1894, to Mar 5, 1895, except for a week of mild weather on Jan 14–21 During almost the whole of this period easterly winds prevailed, which were especially strong in February The greatest intensity of cold occurred from Jan 26 to Feb 19, for which period the average temperature at Greenwich was below 26° F Minimum readings below 0° F were recorded somewhere in the British Isles every day from Jan 8 to 10 and 28, Feb 6 to 14 and 16 to 20, the coldest day being Feb 11 with -17° F at Braemar and -11° F at Buxton At Greenwich the lowest temperature was 7° F on the same day From Feb 9 to 17 the whole of the Thames was more or less blocked by ice, and it was impossible for full powered steamers to force their way up and down except with the tide Some of the ice floes were six or seven feet thick On Feb 18 the ice on the lake in Regent's Park was ten inches thick, in the Fens it was two feet, and at Oxford a coach and six were driven over the Cherwell Water mains were frozen at depths of three feet The frost was the most severe in Great Britain since that of 1813–14, but in Europe the winter, though severe, was not so rigorous as in 1879–80 7° F was recorded at Paris, and the Seine froze on Feb 10 There was heavy snow in France

Feb 12, 1493 Storm—On returning to Spain from his discovery of America, Columbus and his fleet were overtaken by a severe storm, which lasted three days and threatened them with destruction, so much so that Columbus wrote an account of his discoveries and threw it overboard

Feb 12, 1920 Snowstorm in Jerusalem—Twenty-nine inches of snow fell during the six days Feb 8–13 in Jerusalem This was the greatest fall of snow ever recorded there It began with heavy rain and sleet on Feb 8 and 9, a blizzard with wind of gale force blew on the Mount of Olives on Feb 9, but the snow did not lie until that night After that it snowed continually until Feb 12 The total depth of rain and melted snow was equivalent to 10 inches of water The minimum temperature recorded on the Mount of Olives during that time was 25° F Snow fell over a wide area and not only on the hills

Feb 12–14, 1899 Cold Wave—On the morning of Feb 11 pressure over northern Montana rose to 31 42 inches (1064 mb), and temperatures of -20° F were recorded so far south as central Kansas, the lowest being -61° F at Fort Logan, Montana During Feb 12 and 13 the 'high' passed southward over the Great Plains region to the Gulf of Mexico, and temperatures 8° and 13° F lower than previous records were registered at New Orleans and Mobile, Ala, respectively At Tallahassee, Fla, -2° was recorded Snow began to fall in the Ohio Valley on the morning of Feb. 11, and spread southward over the east Gulf and Atlantic States By 8 P M of Feb 13 the storm had become a raging blizzard centred over Cape Cod, with winds of 40 70 miles per hour Many people were frozen to death in the central and northern States, damage valued at millions of dollars was done to fruit orchards, game birds perished by the thousand, and poultry froze in their roosts Swiftly flowing streams froze over and fish were killed, even the Mississippi had one inch of ice at its mouth

Feb 13–14, 1892 Magnetic Storm—A violent magnetic storm accompanied by a magnificent display of the aurora which was visible, in spite of full moon, from Europe (so far south as Rome), Canada, and the United States above lat 36° Telegraphic systems in general suffered dislocation for a few hours The range in declination at Kew and Greenwich exceeded 2° and $1\frac{1}{4}$° respectively, the range at Washington was $1\frac{1}{4}$° At the time a very large sunspot, covering $\frac{1}{350}$ of the sun's visible hemisphere, was one day past the central meridian The region of the spot, which showed abnormal developments on Feb 11 and 12, was one of the first to be explored by Hale with his recently devised 'spectroheliograph' On Mar 11, that is, one solar rotation later as timed from the earth, another magnetic storm of somewhat lesser intensity took place, also accompanied by an aurora

Feb 13–14, 1923 Blizzard—The wind over the plains of North Dakota and Minnesota reached a velocity of more than 50 miles per hour with a temperature below freezing In spite of warnings by the Weather Bureau, more than twenty people froze to death and many cattle died, some of them suffocated beneath the snow The train services on branch lines were interrupted for more than a week, and on Feb 13 no trains ran even on main lines

Societies and Academies

LONDON

Royal Society, Jan 30—R N Salaman Crinkle 'A', an infectious disease of the potato Infection by grafting reproduces the disease in various varieties with certain modifications In one group the clinical picture is still that of crinkle, in another it is mosaic, and in a third, streak Infection by needle inoculation produces a reduced set of symptoms in all cases Crinkle 'A' is a complex of two or more viruses Infection of *Datura* gives characteristic reactions, but the leaves modify the virus, lessening the virulence Passage through tobacco does not increase its virulence —**R N Salaman and R H Le Pelley** Para-crinkle, a potato disease of the virus group Para crinkle is distinguished from crinkle 'A' by the fact that certain varieties highly susceptible to it are perfect carriers of para crinkle, while others, which suffer relatively mildly from crinkle 'A', are seriously affected by para crinkle Para crinkle is due to a single virus, its action can be completely destroyed by the products of metabolism of the leaves of *Datura* Its virulence is increased in those plants which are themselves raised from diseased tubers —**E C Smith and T Moran** The formation of lactic acid in desiccated amphibian muscles Formation of lactic acid in the

frozen state is due to the removal of water alone The peak in the production curve at $-2\cdot2°$ to $-2\cdot5°$ C (79 per cent water removal) is apparently coincident with the point at which death occurs instantaneously in the muscle No sudden change in concentration of any plasma constituent seems to be associated with these events —**H G Thornton** The influence of the host plant in inducing parasitism in lucerne and clover nodules When inoculated lucerne seedlings are placed in the dark, formation of fresh nodules soon ceases, and those already formed cease to grow This is associated with, and probably due to, cessation of cell division The bacteria become parasitic upon the host tissues In old nodules in lucerne and clover, growing in the light, bacteria behave similarly Lack of carbohydrate is the cause of change of behaviour of the bacteria, which then derive their energy from the host tissue —**F Kidd** and **C West** Physiology of fruit (1) Changes in the respiratory activity of apples during their senescence at different temperatures Carbon dioxide production by apple fruit rises for a period and then falls off continually, until the fruit dies as the result of invasion of the tissues by fungal organisms The accelera tion and deceleration of respiration rate have high temperature coefficients Change of respiratory activity is not due to changes in substrate concentra tion related to hydrolysis of sugars, starch, or cell wall materials, but to a change in state of the protoplasm

Geological Society, Jan 8 —Stanley Smith (1) Some Valentian corals from Shropshire and Montgomeryshire, with a note on a new stromatoporoid The Valentian coral fauna is not primitive, and is more closely allied to Salopian than to Caradocian assemblages, nevertheless, the important place occupied by the species of *Streptelasma* in the *Pentamerus* Beds links these up with the Ordovician The Purple Shales, on the other hand, have yielded several species of Rugose corals which are typically Salopian The Tabulate corals are of little interest, except in so far that they prove the very long range of the Lower Palæozoic species, there seems to be little, if any, difference between the Caradocian, the Valentian, and the Salopian forms —(2) The Carboniferous inliers at Codrington and Wick (Gloucestershire) The largest and most interesting is the Wick Rocks Inlier, on the same line of latitude as the Avon Gorge and some 9 miles to the west The several outcrops expose, although not quite completely, a succession of beds ranging from the Tournaisian (Z_2) to Coal Measures The arenaceous beds which succeed the limestone sequence are better exposed in the Wick Inlier than anywhere else in the Bristol district These belong in part to the Lower Carboniferous, in part to the Upper, and within the series (formerly mapped as 'Millstone Grit') a considerable break in the Carboniferous succession must occur The general succession of the Carboniferous in the area under discussion is given The gap between the Lower and the Upper Carboniferous is placed tentatively at the top of the massive grits which contain the 'Mollusca Band'

Linnean Society, Jan 9 —W H Thorpe Further notes on biological races in *Hyponomeuta padella* (Linn) It has been shown previously that the small ermine moth, *Hyponomeuta padella* (Linn) [*H variabilis* Zell, *H malinella* Zell] is split into two well marked biological races, one attached to apple, the other to hawthorn, blackthorn etc Further evidence suggests that the latter form is itself split into two less strongly marked biological races, one attached to blackthorn (*Prunus spinosa*) and the other to hawthorn (*Cratægus Oxyacantha*) —**J T Cunningham** The origin of adaptations Two recent general reviews of the subject of adaptation in animals entirely omit consideration of (1) metamorphosis and recapitulation, (2) sexual dimorphism, especially the relation of these phenomena to internal secretions or hormones Consideration of these subjects is essential to the discussion of animal adaptation The chief general conclusion is that evolutionary changes are of two kinds, namely, those which consist of mutations of internal origin, with no relation to external conditions, and those which have such a relation and can be ascribed to the action of external stimuli

EDINBURGH

Royal Society, Jan 13 —George Bond Occurrence of cell division in the endodermis Endodermal cells frequently show a considerable increase in tangential dimension at a comparatively late stage in their existence This increase in size is often accompanied by their division, the new walls being radially orientated in the main The divisions may actually cause the increase in size of the original cells, or they may follow passive stretching Two types of division are distinguishable (a) Those occurring in primary endodermal cells, (b) divisions in tertiary endodermal cells The second type is the more common, and as many as twenty five successive divisions of this type may occur in one original cell The condition of the endodermal cell at the time of stretching and division determines which type of division appears In neither case does the development of new walls interfere with the efficiency of the endodermis as a physiological barrier — **David G Catcheside** Chromosome linkage and syndesis in *Œnothera* Cytological studies were made upon pollen mother cells of two close pollinated, small flowered species of *Œnothera*, *Œ pycnocarpa* Atk & Bartl and *Œ nutans* Atk & Bartl A single, continuous spireme is formed, the whole diploid complement of fourteen chromosomes is arranged in a ring at diakinesis, the chromosomes being attached end to end A triploid plant of *Œ pycnocarpa* had the twenty one chromosomes arranged end to end in a closed circle The telosynaptic view of chromosome conjugation is supported for the genus the recent parasynaptic hypotheses being examined critically Darlington's theory, that ring formation in *Œnothera* is due to segmental interchange between non homologous chromosomes of the same complex, fails to account for the formation of a ring in the triploid form Support is given to Sheffield's theory that ring formation is an heritable phenomenon controlled by genes in the chromosomes —**D R R Burt** On a case of intersexuality in *Bos indicus*, with a theory of the significance of the genetic male intersex An abnormality is described in which there is a functional ovary on the right side associated with a complete Mullerian duct, and a cryptorchid but small testis on the left associated with a complete Wolffian duct The animal is a genetic male intersex A hypothesis is suggested which postulates the action of a maternal sex hormone in initiating and controlling sex reversal during intra uterine development, the difference between the left and right sides being attributed to earlier differentiation of the left gonad in cattle Actual confluence of the blood vessels of the crypts and villi during development may be responsible for the abnormality This hypothesis reduces the two classes, the free martin and the genetic male intersex, to the same order

PARIS

Academy of Sciences, Dec 30 —A Cotton Asymmetric synthesis and the existence of racemic compounds in solution Some remarks on a recent paper

by Werner Kuhn and E Braun It has been generally held that racemic compounds cannot exist in solution an experiment with a mixture of solutions of lævorotatory and dextrorotatory copper tartrates is described which is regarded as furnishing evidence of the contrary view —**Jean Perrin and Mlle. Choucroun** Fluorescence sensibilised in liquid medium (transfer of activation by molecular induction) —**Marcel Brillouin** The dynamical tides of an ocean comprised between two parallels Simultaneous normalisation —**Charles Nicolle, Charles Anderson, and Jacques Colas-Belcour** The rôle of *Ornithodorus erraticus* in the natural transmission of two recurrent spirochætes The danger of the propagation of recurrent Hispano-Moroccan fever in Algiers and Tunis —**A Gelfond** Transcendental numbers —**Mme M Piazzolla Beloch** The number of odd branches of curves belonging to a surface of the third order —**G Pfeiffer** The integrals of partial differential equations and of systems of equations of the first order of an unknown function, which possess S Lie integrals —**Marcel Brelot** The problem of Dirichlet external in the plane relatively to the equation $\Delta u = c(x, y)\ u$ —**Léonidas Kantorovitch** Projective ensembles of the second class —**J A Lappo-Danilevski** Analytical functions of a single variable substitution —**Oystein Ore** Hypergeometric functions of several variables —**Miloch Radoitchitch** Inverse functions of meromorph functions —**J Petrovsky** Functions primitive with respect to a continuous arbitrary function —**J Haag** The general theory of synchronisation —**Joseph Pérès** A formula for the calculation of the resistance of a solid in an incompressible perfect fluid —**Alex Véronnet** The theory of the formation of large ions and droplets —**L Décombe** Melde's experiment and the conditions of Sommerfeld —**Th Vautier** The dissipation of the energy transported by an aerial wave —**G Reboul** A method of activation of matter —**Michel** The calculation of a galvanometer —**Emmanuel Dubois** The Volta effect The influence of the oxidation of the electrodes For the various metals examined, the presence of oxygen, either adsorbed by the metal, or combined with it, makes the metal electronegative —**Trajan D Gheorghiu** The absorption of dextro- and lævorotatory copper tartrates and of their mixture The measurements were made with a photoelectric photometer The absorption of the two tartrates is the same, but the absorption shown by the mixture is clearly greater —**J Dufay and Mlle R Schwégler** The visual measurement of very small luminosities The object of the experiments was to determine the accuracy with which measurements of faint luminosities of less than 10^{-6} candles could be made —**H Volkringer** The band spectra of zinc vapour Zinc vapour, heated to a red heat in a silica tube, gives a band spectrum when excited by discharge without electrodes Measurements are given of lines between the wave lengths 2983 A and 3282 A From the large distances separating the lines it is concluded that the molecule has a very small moment of inertia The possibility of the spectra being due to zinc hydride is discussed —**René Audubert** The photolysis of water and the photovoltaic effect of electrodes of gold and platinum —**Mlle Marguerite Quintin** The influence of the medium on the photovoltaic effect of iodide of copper The results given show that the phenomenon depends upon the action of light both on the liquid and on the photosensitised substance —**Mlle Iréne Curie and Frédéric Joliot** The nature of the absorbable radiation which accompanies the α-rays of radium Strong preparations of polonium produce in air an heterogeneous H radiation (maximum path about 16 cm of air) and these probably result from a transmutation of nitrogen It is this radiation which was taken for a γ radiation of polonium in the experiments of Russell and Chadwick —**E Rinck** The equilibrium in the fused state between potassium, sodium, and their iodides In this reaction the law of mass action $(Na)(KI)/(K)(NaI) = c$ has been verified, the mean value of the constant c being 56 —**Néda Marinesco** Dielectric polarisation and structure of absorbent colloids —**J Séailles** A new method for the preparation of alumina in the wet way —**L Andrieux** The preparation and properties of the borides of tantalum and colombium The general method is the electrolysis of fused baths of mixtures of the oxide of tantalum (or columbium), magnesium (or calcium, lithium, sodium), borate and a fluoride The borides obtained proved on analysis to be TaB_2, CbB_2 They are very hard and easily scratch quartz —**E Carrière and Rouanet** The estimation of fluorine as calcium fluoride —**P Fleury and P Ambert** The precipitation of sugars and of polyols as a cupro baryta complex —**Raymond Charonnat and Raymond Delaby** The constitution of dioxypyramidon By total and partial alkaline hydrolysis the constitution of this substance is proved to be CH_3 CO $N(CH_3)N(C_6H_5)CO$ CO $N(CH_3)_2$ —**Georges Darzens and André Lévy** The primary phenyl dimethyl ethyl alcohol and some of its derivatives —**C Gaudefroy** Half wave and quarter wave achromatics by the superposition of several crystalline plates —**P L Mercanton** Observations made on board the *Pourquoi Pas?* with the pycnosonde of La Cour and Schou (summer 1929) Proofs of the value of this new instrument —**R Bureau** The daily variation of atmospherics monthly means, annual variation, meteorological influences —**J J Thomasset** The calcospherites of fossil tissues —**Mlle Germaine Py** Cytological researches on the nutritive layer of the pollen grains of *Helleborus fœtidus*, *Euphorbia Sauliana* and *E Peplus* —**B P C Hochreutiner** A new genus modifying slightly our conception of the family of the Malvaceæ —**N Wagner** The chondriome of the embryo in *Cucurbita Pepo* in the dry seed and during germination —**M Bridel and J Rabaté** The distribution of piceoside (Ch Tanret's piceine) in the vegetable kingdom Piceoside, the glucoside of *Picea excelsa*, salinigrine, glucoside from the bark of the black willow and ameliaroside, glucoside from *Amelanchier vulgaris*, are all the same substance, the β- glucoside of *p* hydroxy-acetophenone —**E Michel-Durand** The influence of treatment with alcohol on the extraction of tannin from plants A preliminary treatment of the acorns of *R robur* with boiling alcohol renders the tannins insoluble in acetone —**Aug Chevalier** *Striga hermonthica*, a Scrophularia parasite on cereals in tropical Africa —**A Demolon and G Barbier** The fixation and mobilisation of phosphorus pentoxide in muds —**Pierre Lesne** The distribution of *Glossina* in the region of the Zambeze de Chemba (Portugese Eastern Africa) —**C N Dawydoff** The presence of the genus *Ctenoplana* in the waters of French Indo China —**Jacques Colas-Belcour** The identity of *Ornithodorus erraticus* and *Ornithodorus marocanus* —**N K Koltzoff** The element of time in physico-chemical excitability —**Jean Régnier and Fernand Mercier** Dextrorotatory pseudococaine and lævorotatory cocaine, comparative trials of rachianæsthesia in the dog —**J Lemarchands** The proportions and the localisation of the carbohydrates in the seed of *Helianthus annuus* and their variations in the course of germination —**Léon Velluz** The action of soaps on the toxicity of certain alkaloids (cryptoalkaloids) The toxic action of strychnine and veratrine is reduced by solutions of soaps (sodium palmitate, sodium ricineolate) —**Ch Champy and M. Heitz-Boyer** The mechanism of the action of the high frequency electric cautery Study of the me-

chemical effects of high frequency currents their hæmostatic action on the vessels —**Léon Binet** and **Charles Mayer** A new technique of blood perfusion — **C Levaditi** and **F R Selbie** The mode of transmission of acute epidemic polymorphous erythema The mouse is subject to a spontaneous generalised infectious polyarthritis, caused by *Streptobacillus moniliformis*, the pathological agent of certain infectious polymorphous erythemas It appears to play an important part as the reservoir of the virus and agent of transmission of the disease

Diary of Societies

FRIDAY, FEBRUARY 7

ROYAL SOCIETY OF MEDICINE (Otology Section), at 10 30 A M —Prof Neumann, E M Atkinson and H W B Cairns Discussion on Brain Abscess

ROYAL SOCIETY OF ARTS (Indian Meeting) at 4 30 —G H Tipper Recent Mineral Developments in India

ROYAL SOCIETY OF MEDICINE (Laryngology Section), at 5

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 —Sir John Rose Bradford Massive Collapse of the Lung

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute, Newcastle upon Tyne) at 6 —S. S Cook High Pressure Steam for Marine Work

SOCIETY OF CHEMICAL INDUSTRY (Birmingham and Midland Section) (at Chamber of Commerce, Birmingham), at 6 30 —A. G Lobley Electric Furnaces for Heat Treatment

SOCIETY OF CHEMICAL INDUSTRY (Manchester Section) (jointly with Institute of Fuel) (at Engineers Club, Manchester), at 7 —Prof M W Travers The Fundamental Problems of Fine Gas Purification

INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section), at 7 —G F Shotter A New Null Method of Testing Instrument Transformers and its Applications —R J S Spilsbury and Dr A. H M Arnold Some Accessory Apparatus for Precise Measurements of Alternating Current.—Dr A H M Arnold Precision Testing of Current Transformers

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group) at 7 —Practical Evening

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Graduate Section) (at Bolbec Hall, Newcastle upon Tyne), at 7 15 — W G Thompson The Electrical Propulsion of Ships

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (at Royal Metal Exchange Swansea), at 7 30 —W R Barclay Nickel Alloys in Modern Engineering

JUNIOR INSTITUTION OF ENGINEERS at 7 30.—G F O Riordan Co-operation between Technical Institutions and Industry

GEOLOGISTS ASSOCIATION (Annual General Meeting) (at University College), at 7 30 —Prof A Morley Davies The Geological Life Work of Sydney Savory Buckman (Presidential Address)

LEICESTER TEXTILE SOCIETY (at Victoria Hall, Leicester), at 7 30 — A Welch Celanese Yarns and Fabrics and their General Characteristics.

PHILOLOGICAL SOCIETY (at University College), at 8 —Prof V G Childe Philology and Archæology

ROYAL SOCIETY OF MEDICINE (Anæsthetics Section) at 8 30 —C L Hewer and I W Magill Discussion on Anæsthesia in Thoracic Surgery

ROYAL INSTITUTION OF GREAT BRITAIN at 9 —Prof L Hill Diving

OXFORD UNIVERSITY JUNIOR SCIENTIFIC CLUB —Dr R. G Canti The Canti Cancer Film, showing the Effect of Radium on Cancer

SATURDAY FEBRUARY 8

MINING INSTITUTE OF SCOTLAND (at 79 Grassmarket, Edinburgh), at 3 — Sir Thomas H Holland Address —Discussion on J E Lambert's paper on Some Notes on Colliery Blasting Practice H A. Peach's paper on The Lochaber Water Power Scheme and its Geological Aspect.

ROYAL INSTITUTION OF GREAT BRITAIN at 3 —Rev G Cooke Tonality and Form

PHYSIOLOGICAL SOCIETY (at St Bartholomew's Hospital Medical College), at 3 30 —Demonstrations —Prof F L Hopwood Some Physiological Effects of Ultrasonic Sound Waves —Prof H Hartridge (a) Vacuum Reaction Velocity Apparatus (b) Reversion Eriometer —E M Landis and T Lewis A Case of Raynaud's Disease treated by Cervical Sympathectomy —A W Spence On the Effect of a Vitamin Deficient Diet on the Thyroid Gland of Rats —R Hilton (a) A Nose Piece for Administering Oxygen (b) A Simple Mouthpiece of Low Resistance for Collecting Expired Air during Dyspnœa —M Landis Micro-injection Method for Direct Determination of Blood Pressure in Single Capillaries of Human Skin —M O P Wiltshire Effect of Liver Tissue on the Rate of Destruction of Adrenaline —E A Carmichael and A Q Wells The Tissue Culture and Vital Staining of Microglia.—Prof H Hartridge and R. G R West Apparatus for Testing Electrical Reactions —At 4.45 — Cinema Films Demonstrated by A C Denny and J F Rogers.—Movements of Alimentary Tract in Experimental Animals by Drs. Carlson and Luckhardt —Drugs on Gastric Intestinal Motility, by Drs Kellogg and Dowd —At 5 30 —Communications —F Haynes Physiological Aspects of the Reaction of the Lungs to Inhaled Dusts —H G Reeves Dihydroxy acetone on Smooth Muscle —Prof H Hartridge and R G R West Chronaxie and Rheobase —Prof A V Hill The Change of Water Vapour Pressure caused by Substances added to Blood —F R Winton Tonus in Mammalian Plain Muscle.—M O P Wiltshire On the Rate of Oxidation of Adrenaline and the Assumed Sensitisation of Intestinal Muscle by Blood, Serum and Tissue Cells.—Mary Pickford and Dr E B Verney A Method of producing and studying the Effects of Acute Arrest of the Renal Circulation in the Unanæsthetised Dog.

MONDAY, FEBRUARY 10.

CAMBRIDGE PHILOSOPHICAL SOCIETY (in Comparative Anatomy Lecture Room), at 4 30 —Prof J Barcroft Blood Storage —Dr J. Needham Nuclein Synthesis in Developing Eggs.—J T Saunders Water Movements in Lakes.—Dr A. Bishop The Culture of Trichomonas

BIOCHEMICAL SOCIETY (at Lister Institute), at 5 —R. Robison, M MacLeod, and A M Rosenheim Calcification *in vitro* —C R. Harington and W T Salter Enzymic Hydrolysis of the Thyroid Gland —P J G Mann and B Woolf The Action of Salts on Fumarase. I —V B Wigglesworth A Theory of Tracheal Respiration in Insects.—E Boyland Pyrophosphate in Yeast Preparations.—R. H Marriott The Action of Alkalis on Collagen —F Wokes Note on the Specificity of the Colour Tests for Vitamin A.

ROYAL SOCIETY OF MEDICINE (United Services Section), at 5 —Wing Comm H A Treadgold Cardiac Functional Efficiency in the Young Male Adult.

INSTITUTION OF AUTOMOBILE ENGINEERS (Joint meeting of Birmingham Centre and Graduates Branch) (at Queen's Hotel, Birmingham) at 7 —L H Dawtrey Automobile Brakes

INSTITUTION OF ELECTRICAL ENGINEERS (North Eastern Centre) (at Armstrong College Newcastle upon Tyne), at 7 —T W Ross and H G Bell Recent Developments in the Protection of Three phase Transmission Lines and Feeders

INSTITUTION OF HEATING AND VENTILATING ENGINEERS (Associate Members and Graduates Section) (at Borough Polytechnic), at 7 —B T Wingfield Automatic Control in Heating and Air Conditioning Installations

MANCHESTER ATHENÆUM TEXTILE SOCIETY (at Manchester), at 7 —W Wilkinson The Weaving of Fancy Cloths

INSTITUTE OF METALS (Scottish Local Section) (at 39 Elmbank Crescent Glasgow), at 7 30 —S H Hawkins Pyrometry

MEDICAL SOCIETY OF LONDON, at 8 —Dr Maurice M Davies, and others Discussion on The Surgical Treatment of Pulmonary Tuberculosis

SURVEYORS INSTITUTION at 8 —J L Milne The Rating and Valuation (Apportionment) Act, 1928

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8 30 —Col F L Giles Boundary Work in the Balkans

INSTITUTION OF ELECTRICAL ENGINEERS (Western Centre) (at Cardiff).

ROYAL IRISH ACADEMY (Dublin)

TUESDAY, FEBRUARY 11

ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15 —Sir William Bragg X Ray Determination of the Structure of Cellulose and Similar Substances (1).

INSTITUTION OF CIVIL ENGINEERS, at 6 —R. W S Thompson The Diversion of the River Ashop

INSTITUTE OF MARINE ENGINEERS at 6 30 —C H Faris The Applications of Electro deposited Metals to Marine Engineering

INSTITUTION OF ELECTRICAL ENGINEERS (East Midland Sub Centre) (at Loughborough College), at 6 45 —G R J Parkinson Electrical Development.

INSTITUTION OF ELECTRICAL ENGINEERS (North Midland Centre) (at Hotel Metropole Leeds) at 7 —Dr J Hartmann The Jet Wave Rectifier The Experimental and Theoretical Basis of its Design

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN at 7 —Dr I C Martin Studies in Colour Vision

INSTITUTION OF ELECTRICAL ENGINEERS (Scottish Centre) (at Royal Technical College, Glasgow), at 7 30 —W B Hird The Visit of the Institution to France

INSTITUTE OF METALS (North East Coast Local Section) (at Armstrong College, Newcastle upon Tyne) at 7 30 —W Richardson Electric Heating

QUEKETT MICROSCOPICAL CLUB (Annual Meeting) (at 11 Chandos Street W 1), at 7 30 —J Ramsbottom Presidential Address

EUGENICS SOCIETY (at Linnean Society) at 8 —E J Lidbetter and others Discussion on Poor Law

LEICESTER LITERARY AND PHILOSOPHICAL SOCIETY (Chemistry Section) (jointly with Leicester University College Biological Society) (at University College Leicester), at 8 —Prof R. H A Plimmer Proteins in Nutrition

ROYAL ANTHROPOLOGICAL INSTITUTE at 8 30 —Miss G Caton Thompson Recent Excavations at Zimbabwe and other Ruins in Southern Rhodesia

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN at 8 30 —Prof T G Hill The Biologic Factor in Plant Anatomy

WEDNESDAY, FEBRUARY 12

INSTITUTION OF HEATING AND VENTILATING ENGINEERS (at Holborn Restaurant) at 2 30 —S Fox Half a Century of Boiler Making.

INSTITUTE OF METALS (Swansea Local Section) (at Thomas's Café Swansea), at 7 —Dr A G Ramsay The Corrosion of Non ferrous Metals.

SOCIETY OF CHEMICAL INDUSTRY (Newcastle Section) (at Armstrong College, Newcastle upon Tyne), at 7 30 —Dr E G Ritchie Steam Storage in the Manufacturing Industries.

INSTITUTION OF ENGINEERS IN CHARGE (at St. Bride Institute), at 7 30 —H E Stilgoe The Water Supply of the Metropolis

HALIFAX TEXTILE SOCIETY (at White Swan Hotel, Halifax), at 7 30 —C R. Spedding Rags—their Origin and Uses

ROYAL SOCIETY OF ARTS, at 8.—H Jackson Colour Determination in the Fashion Trades

THURSDAY, FEBRUARY 13.

ROYAL SOCIETY, at 4 30.—Probable Papers —G Slater Studies on the Rhone Glacier, 1927 The Structure of the Ice in a Compressed Zone on the South Eastern Part of the Rhone Glacier —T Goodey On a Remarkable New Nematode *Tylenchinema oscinellae* gen. et sp. n parasitic in the Frit-fly, *Oscinella frit* L, attacking Oats.—D E Sladden Distortion of Development in Amphibia caused by Lack of Oxygen in very Early Stages in Development.—*To be read in title only* —Sir Frederick Keeble, M G Nelson, and R. Snow The Integration of Plant Behaviour Part II The Influence of the Shoot on the Growth of Roots in Seedlings —A W Greenwood and J S S Blyth The Results of Testicular Transplantation in Brown Leghorn Hens.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15 —T A. Joyce Architecture and the Industrial Arts of Pre-Spanish America (1).

INSTITUTION OF CIVIL ENGINEERS (Informal Meeting), at 6 —L. A. Legros The Influence of the Progress of Aeronautical Engineering on other Branches of Engineering Work.

INSTITUTION OF ELECTRICAL ENGINEERS at 6 —Dr J Hartmann The Jet Wave Rectifier The Experimental and Theoretical Basis of its Design

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 6 30—J de la Cierva Recent Progress with the Autogiro

INSTITUTE OF MARINE ENGINEERS (Junior Section), at 6.30—S N Kent Discipline as applied to the Engine Room etc.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Colour Group—Informal Meeting), at 7

INSTITUTION OF ELECTRICAL ENGINEERS (Dundee Sub-Section) (at University College, Dundee) at 7 30 —G H Chalmers Lubrication

INSTITUTE OF METALS (London Local Section) (at 83 Pall Mall), at 7 30 —H H Smith Temperature Measurement and Control in Works

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Tees side Branch) (Informal Meeting) (at Cleveland Institution Middlesbrough) at 7 30 —W T Butterwick and others Discussion on Are Government Regulations Effective in Preventing Marine Casualties?

OPTICAL SOCIETY (at Imperial College of Science and Technology), at 7 30 —F Twyman Optics in Radio Transmission and other Fresh Fields (Presidential Address).

FRIDAY, FEBRUARY 14

GENETICAL SOCIETY (at John Innes Horticultural Institution Merton), at 2 30 —Experiments on *Primula Sinensis* —Miss de Winton and J B S Haldane Demonstration of the Genetics of Diploid and Tetraploid Forms —Dr C D Darlington Exhibition of Cytological Preparations of the Tetraploid —Dr F W Sansome Exhibition of Slides Illustrating Pollen Behaviour in the Tetraploid —J B S Haldane The Genetics of the Tetraploid

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 4 —E W Hey Groves The Hunterian Oration

ROYAL ASTRONOMICAL SOCIETY (Annual General Meeting) at 5 —Presidents Address on the Award of the Gold Medal to Dr J S Plaskett for his Valuable Observations of Stellar Radial Velocities and the Important Conclusions derived from them

PHYSICAL SOCIETY (at Imperial College of Science) at 5 —W E Summerhays The Diffusion Constant of Water Vapour —M C Johnson A Method of Calculating the Numerical Equation of State for Helium below 6 Absolute and of Estimating the Relative Importance of Gas Degeneracy and Interatomic Forces —F D Smith The Magnetostriction Constant for Alternating Magnetic Fields —Demonstration by D Kempson of A Working Model illustrating the Mosaic Theory of the Compound Eye due to Altenburg

MALACOLOGICAL SOCIETY OF LONDON (at Linnean Society of London) at 6 —Annual Meeting

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting) at 7 —G S Taylor Lantern Lecture

OIL AND COLOUR CHEMISTS ASSOCIATION (Manchester Section) (at Milton Hall Manchester) at 7 —R G Daniels Common Sense and Nitro cellulose Lacquer

INSTITUTION OF AUTOMOBILE ENGINEERS (Coventry Centre) (at King's Head Hotel Coventry) at 7 30 —L H Pomeroy The Double six Engine

JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting) at 7 30 —Technical Film—The Manufacture of Staybrite and Stainless Steels

INSTITUTE OF METALS (Sheffield Local Section) (at Sheffield University) at 7 30 —S Matthews Recent Developments in Measuring Instruments

Unemployment and Hope

EVEN the most strictly scientific mind may, at the approach of spring, be allowed to wander somewhat out of the old and beaten track—indeed the scientific mind should be constantly on the search for new tracks—to indulge in flights of imagination and of hope, especially of hope It is the season of new hopes, new resolves, new thoughts, and though the hardened cynic may smile at their apparent futility, yet, however often we fall and fail, it is best to go on trying and keep the shining portals of hope, far distant though they be, still in view *Dum spiro, spero* So, in our title we have included hope, even in connexion with unemployment, and thus very flagrantly broken that excellent rule of the strictest school of economics which would rigidly exclude from consideration everything outside the indicative mood, and certainly everything appertaining to the optative mood (*vide* Prof Florence in his recent work on statistical method in economics)

In the following few notes and crude suggestions the point of view is taken that we should make the best of our present industrial civilisation, that that best is better than is often imagined, that perfect safety in the cosmic adventure, perfect ease, pleasure, and a generally 'soft time' for everybody, are unattainable, that danger and difficulty are always present and will increase in proportion as we advance, and that this progressive advance in the face of increasing danger and difficulty is the thing best calculated to develop a nation's highest qualities Nothing revolutionary is proposed, for a fairly thorough comparative study of economic systems past and present, including many so-called Utopias, has convinced us that nothing revolutionary can be proposed on any rational basis

Our present industrial society has many elements of strength and stability, and even of nobility, to which attention has been only slightly or not at all directed, and many elements of weakness on which attention has been unduly concentrated There is much that is sound and healthy, as is evidenced by the amazing fact that, despite the overwhelming ills with which it is supposed to be afflicted, society has continued as a going concern to this day in wonderful vigour, whereby millions are enabled to live a fairly healthy, active, and more or less happy life, and wherein hundreds of thousands find scope and opportunity—of which, to their unbounded credit, they fully avail themselves—for exercise of the highest virtues of integrity, skill, and courage These elements and

scope for their exercise can be increased almost indefinitely, and much that is evil will thus automatically be reduced or held in check; but not, perhaps, altogether exterminated, for the mysterious shadow of evil remains a sinister spectre in the background of all man's endeavour, leading him constantly into danger, and spurring him ever to greater efforts. It is well that it is so.

The aims of industry are, or should be, as indicated in a previous article, chiefly two: (1) to furnish a field for exercise of faculty and growth of character; and (2) to produce commodities to satisfy man's varied wants, mostly of a material kind, though of course there are large exceptions outside the material category, and the term 'material' is here used in no derogatory sense. Attention has hitherto been directed mainly to (2) and the primary aim of industry has been ignored. Such one-sided view of industry coupled with a too narrow use of the much abused word 'evolution'—as we shall see later—has led to over-concentration on quantity and mass production and a ridiculous neglect of the human element; and there can be no doubt that had a little thought been given to the first aim, then the second would have been much more completely and satisfactorily attained; also unemployment would not have been heard of, and, as pointed out, too, in the article referred to, the right use of leisure would have been treated rationally as a dominant factor.

Revolution being excluded, one has naturally turned to evolution as correctly expressing society's progress, assuming that progress in the right direction is being made; Ely's "Studies in the Evolution of Industrial Society" being a noteworthy contribution to the evolutionary view. But the use of the term evolution should not lead us to suppose that modern industry is evolving into some perfect and complete type or consummation. Existence would be very dull and dreadfully boring when such a state had been reached, with nothing left to hope and strive for. Then again, the best form or type of industry may not be and surely is not necessarily one particular fixed static type or form only, but may consist of many different and constantly changing forms, distinguished above all things by adaptability and elasticity—a living organism.

The prevailing idea, with exceptions here and there, appears to be that industry is evolving and must evolve towards one fixed type, for example, that of large scale production, with division of labour and specialism and consequent monotony of work pushed to still more disastrous extremes. But it is doubtful if this supposed ideal or consummation would work very long, or prove to be the best even from the merely material point of view of quantity production, and it would of course altogether ignore the spiritual aims of industry, namely, scope for development of faculty, character, and sound citizenship. This latter is a vital consideration, for the political strength of a nation is dependent on a spiritual or ethical view of industry.

What is to be more specifically understood as elasticity in the industrial structure is the provision of opportunity for other forms than that of large-scale production only, to develop and see what they can make of themselves. Beside large-scale production, or, more strictly, large-scale capitalistic production, there is co-operative production, which of course may be only another variety of large scale working but may also include much on the small scale. Large scale also may mean a conglomeration of several small and nearly independent units, such as an association of small dairy farmers, small village artisans or handicraft workers, and many such like. Elasticity further means the possibility of reviving, under new and improved forms to meet modern conditions, two at least of the older types of industry which are supposed to have been superseded or rendered obsolete by modern large scale production; namely, (1) small cottage industries or handicrafts, sometimes known as 'village industries' or 'home work' (in the factory inspector's reports) and sometimes as 'sweated industries'—as many of them are, though they need not, of course, be 'sweated', for this is an evil excrescence not essentially inherent; (2) a combination of manufacturing with agricultural or garden industry, including the possibility of providing the industrial classes with some form of land interest (see NATURE, Mar. 9, 1929, p. 341). If the evolutionary doctrine, as applied by Herbert Spencer and others to the social body, means that these and perhaps other and older forms of industry are useless anachronisms and may not contain something of vital value at the present day, then its application here has been profoundly erroneous and disastrous, stupid and short-sighted. Industry still has its roots firmly and deeply fixed in the past, and foolishly to tear up a great part of those roots as old and useless is the surest way to weaken the industrial tree. Perchance the source of the unemployment curse is to be found here.

The restitution of these two principles of an older industrial order, so essentially and characteristically English, under improved forms made possible by modern scientific achievement, including notably

electrical power distribution, would furnish, in the first place, a new and almost infinite field for human employment of all kinds, absorbing all or most of the present unemployed, giving extra occupation to those on short time, also scope for much organising talent and business ability now running to waste—a lot of it among the idle or leisured classes—through lack of opportunity. By unemployed we mean chiefly the unemployed in Great Britain only, but it would be vastly better to extend our consideration to cover unemployment throughout the whole world. For, first, this would provide a splendid additional bond for international co-operation and friendship, of which we cannot have too many; and, secondly, the solution or even partial amelioration of the unemployment problem in other countries would be bound to have advantageous repercussions on unemployment in Britain.

By accepting these two principles as a basis, with or without some kind of financial reform in the direction of a measurable amount of inflation, possibly on the lines suggested by Arthur Kitson, Douglas, and others, an approach can be made to the unemployment problem, as was done a few years ago rather successfully with the Greek refugees. The application of these two principles to unemployment is, of course, only one part of their scope, for they have a far wider range even than this, especially in counteracting one of the greatest evils of modern industry, namely, extreme specialism, monotonous work, and lack of scope for developing skill, with all that that implies.

Amid much controversy on unemployment, its causes and cures, one fact stands out in unmistakable clearness, and may safely be taken as a starting point. That is, the unemployed must have the wherewithal to live—food, raiment, shelter, and probably a few things above this wretched minimum. Can they be put in a position to supply most of these things for themselves? At present they lack a market for their labour, and yet they are themselves a huge potential market for labour and the products of labour. Another indubitable fact, standing clear above controversy even though it comes from the realm of economics, is that the instruments of production are land, labour, capital, and organisation or management. There is plenty of land available or reclaimable in Great Britain. Millions of pounds of capital could be provided by capitalising the 'dole' for five or ten years. The requisite organising and managerial ability is doubtless also in existence, but will have to be diligently sought out; much of it would probably be found or developed among the unemployed themselves, who also would supply the greater part of the labour.

The aim would be to establish a vast productive organisation, consisting in the main of village communities and garden cities, containing both large factories—if need be—and also cottage or home industries and handicrafts. A considerable amount of whole-time intensive farming probably on a large scale, together with market gardening and fruit growing, would be provided for; but a fundamental feature of the scheme would be a land interest for everybody, mostly a part-time interest wherein they could spend much of their leisure, and would include the possibility of owning homesteads containing up to quarter of an acre or more of land, part of which would be orchard. Training in some form of skilled handicraft would also be available to everybody.

These ideas could of course be applied to British industry generally, and not only to the organisation above mentioned, and thus some sort of antidote at least would be provided against two of the most serious evils of modern industrialism—complete alienation from the land and all that this means, on one hand, and entire lack of scope for exercising skill, on the other. A further evil, that of fluctuating employment, could also be met and means afforded for absorbing or 'damping out' a great part of these miserable fluctuations in labour demand; and something would have been done towards encouraging the right use of leisure, a vital matter in modern society, the implications of which are as yet too little appreciated. Science and research would play a dominating part, and large research institutes, especially in connexion with horticulture and growing under glass, would be established; also electrical or other forms of power would be utilised to the utmost, and though the term 'handicraft' may well be retained, it is fully intended that all the resources of modern science and engineering should be applied and every encouragement given to the further development of such resources.

It is probable that, under the more bracing atmosphere of varied work and interest and skill thus envisaged, the inventive faculties of mankind would be greatly stimulated, and a much needed spur be given to originality. It is doubtless difficult enough to generalise in regard to such an elusive thing as a nation's inventive talent or to trace the laws of its rise and fall; but it does seem to keen observers that, in view of the attention now devoted to education and research, the amount of originality and creative talent shown is a little

disappointing We refer not only to the mechanical or physical realm—perhaps it is fairly satisfactory here—but also to other departments of intellectual activity In the social sciences particularly, the lack of originality is deplorable, and outside empiricists are allowed to have their own way without let or hindrance or effective rejoinder

If there is any such decline in originality and inventiveness, the chief cause is probably extreme specialism In Adam Smith's time, division of labour may have been rightly included among the sources of invention to day, in its present extreme form, it is very likely a potent agent of torrefaction, and the springs of intellectual creativeness are dried up But never before in the history of the world has there been a greater or more urgent need for originality and freshness of view than now, and freshness of view includes seeing old ideas in a new light, old principles in new applications and environment

W G LINN CASS

The Structure of St Paul's Cathedral

St Paul's Cathedral By Arthur F E Poley With introduction by Sir Reginald Blomfield (Printed for the Author, "Willowbank", Hampton Hill, Middlesex) £7 7s net

THE author of this magnificent monograph to the genius of Sir Christopher Wren, as exemplified in the neo-classic masterpiece of St Paul's Cathedral, has produced with immense skill a work adequate for its subject Just and yet sensitive feeling, a perfection of refinement in draughtsmanship, and a devoted patience in execution, are distinctive throughout this work The standard set is high indeed and has reached the peak of accomplishment, it has been held there throughout, with an almost grim determination If there is a sense of effort in the monograph—a feeling as of a continuous striving—throughout this great record, which is not too apparent in the original work itself—that must be set down to the invariable difference between the soaring accomplishments of genius and those of the more mundane service of the historian, which last must pursue naturally a more pedestrian route, and follow the way of prose This, of course, will always be apparent unless the supreme artist enlightens us with his appraisement and knowledge, as reflecting on the work of another artist, for he alone could bring to the matter that unimpeachable intuition of the artist and the craftsman, native to the medium in which both work

The text of Mr Poley's monograph is also excellent, but its outstanding merit is the painstaking, amazingly patient, and skilful draughtsmanship reproducing with complete accuracy all the details of this supreme work of architecture

The volume contains matter historical and biographical, with building accounts and practical data, all entirely admirable in their way, but, perhaps wisely, no attempt has been made to examine into and explain the vast statical problem which faced Sir Christopher Wren in the technical resolution of his design

Wren was a fine mathematician, and it is perhaps fair to assume that coming comparatively late to the practice of architecture, he was not intimately acquainted with the practical science of the nature of materials and their behaviour under loading, or their interaction when erected into a structure in intimate association, all parts of the problem of architecture which call for the closest scrutiny into their maximum resistances under compressive and tensional stress

As a slight evidence of this supposition, witness Wren's surprising action in building into the eight great piers supporting the immense load of St Paul's dome (some 50,000 tons approximately), a core of rough mortared, uncoarsed and unbonded fragments of soft Caen stone, and indurated chalk, many fragments calcined by the fire of the old cathedral,* and all taken from the demolished building which preceded his own

It might well have been thought that Wren would have recognised that such a core would be unequal in bearing capacity to the external skins of his piers, faced with Portland stone This one factor in the problem of the preservation of St Paul's must have presented a serious difficulty to the highly expert committee dealing with the repair of the Cathedral, and must indeed remain a matter of anxious concern for all those in charge of the structure in the future

Again, Wren in his work at Hampton Court suffered odium from his enemies as a result of the fall of the east wall of the Palace consequent upon his building this wing across the recently filled section of the long canal at its west end

At St Paul's, Wren apparently built the foundations of his mighty church partly on soil compressed and loaded by the previously built cathedral, and partly upon unloaded and virgin soil, inevitably incurring a risk of relative settlements, as can indeed be found to have occurred in an examination of the structure to-day

Instances of this apparent lack of the strictly technical or merely practical knowledge of the use

of materials and the incidence of loading in building, can be multiplied, yet so profound and masterly was Wren's grasp of the main statical problems of his work, that these presumed defects in his science of construction—or shall we say this early lack of experience in building practice?—have not apparently imperilled as yet the great work which he did throughout the metropolis They must, however, cause serious heart searching on the part of those charged with the important responsibility of preserving all the work of his genius for posterity, unaltered and in their complete integrity

The authorities of St Paul's are, we believe, fully alive to their responsibility in this matter, and the wise assiduity with which Canon Alexander discovers and criticises any proposal which may be held likely to disturb the *status quo* or the conditions of solum, etc, surrounding the Cathedral, is evidence of this

The new architectural technique which has been slowly developed within the last half century, directed to the examination and understanding of the structural stability of old buildings, and the statical conditions which remain as a result of centuries of depreciation and change in the materials of which they were constructed, will, in the future, we feel sure, be capable of making accurate and yet conservative judgments as to how all the buildings and structures which we consider of vital importance as regards their preservation, can be retained for the future without prejudice to their architectural and historic amenity

It is a great advance in any event that structural work of preservation should be recognised as involving a different technique from that required by the erection of new structures, and Wren's great cathedral will, in the future, set many and intricate problems for resolution to those who are peculiarly qualified to deal with the changed stability factor in the buildings which survive the onrush of our modern civilisation Nothing, however, can dim Wren's genius He treated the renaissance with a freedom, audacity, and original sense of beauty which has never been surpassed, certainly in England His character contributed to his success, he was a man of deep and simple faith, witness his last words when very old, out of favour with the Court, fallen on evil days and evil tongues, in his little house which he had leased on the Green at Hampton Court He wrote "If I glory, it is in the singular mercy of God, who has enabled me to prosecute and finish my great work so conformable to the ancient and true model"

These words show his benign and serene spirit he had served the Crown and the public for fifty years, with supreme genius and confident activity, and saw the patent which he had received from Charles II withdrawn He was succeeded in office by an incompetent, who was unable to maintain the position for even a year, but Wren's work remains an outstanding possession for all time F B

Intensive Drying of Gases and Liquids

The Effects of Moisture on Chemical and Physical Changes By Dr J W Smith (Text Books on Physical Chemistry) Pp xii + 235 (London, New York and Toronto Longmans, Green and Co, Ltd, 1929) 15s net

THIS is a book which has long been needed It is a laborious compilation of all the work, until 1928, which has been done on intensive, or as it has been called by Longinescu, ultra drying A really satisfactory book it is not All the researches described are put on a level, there is no attempt made to deal critically with the different pieces of work The consequence is that in cases still under discussion, such as the dissociation of ammonium chloride, some researches which are obviously faulty are given the same weight as those which have been done with the greatest care Dr Smith has done one successful piece of work in this field, but he would probably be the first to acknowledge that he has neither the experience nor the knowledge which would enable him to deal faithfully with the work he describes Perhaps only half a dozen persons in the world could have done this adequately, and probably no one of them would have undertaken the labour of compilation so well done by Dr Smith

H B Dixon must be regarded as the founder of this branch of chemistry His discovery, just fifty years ago, of the inertness of a dried mixture of carbon monoxide and oxygen to an electric spark, was the *fons et origo* of all the true cases of intensive drying He was a pupil of A G Vernon Harcourt, perhaps the most careful worker in the history of chemistry, and a good deal of his care and attention to minute detail Dixon has been able to hand on to some of his own students It is noteworthy that only one substance is capable of acting as a true drying agent Phosphorus pentoxide owes its unique excellence in this respect to the fact that the product of its action on water is extremely stable Metaphosphoric acid can be distilled without decomposition at a bright red heat without giving up water Hence the water which phosphorus pentoxide absorbs, it retains It has, in addition, the

advantage of being, when pure, inert to a large number of chemical substances

For those who intend to work in this fascinating field, special training and a special attitude of mind are necessary It is not work for the slap-dash, get results quickly type of chemist It is hard to possess one's soul in patience when one reads papers, even in journals of good repute, which describe so-called repetition of older work In one series of papers on the boiling point of liquids, phosphorus pentoxide was introduced into an apparatus containing benzene, and the glass walls were given no chance of drying, since the desiccating agent was submerged in the liquid In another paper ammonium chloride (guaranteed by the makers as chemically pure !) was used, in spite of the fact that, as the authors admit, the salt turned yellow on heating In the work of which this is supposed to be a repetition, the ammonium chloride was boiled with nitric acid to destroy amines, sublimed and re crystallised eight times from the purest distilled water In the ideal book on the subject, such papers would either have been ignored or their errors pointed out, instead of allowing them to cloud the issue as Dr Smith has done

A good preliminary training for this class of work would be the determination of an atomic weight, since any error at once manifests itself by a discrepancy in the result It must be remembered, however, that the standard of purity of material and care in handling are very much higher than in atomic weight work, since the harmful quantities are imponderable Dust, often invisible, is probably at the root of many failures A practice has risen, in both the United States and Germany, of attempting to dry a glass surface by heating in an electric furnace while the apparatus is exhausted This method " which must produce at least as dry a surface as that attained by Baker " (*sic*) does not get rid of dust as does the standard method of heating the apparatus while a current of purified and dried air is passed through it It is necessary to burn up the invisible dust particles, for water is not the only effective catalyst It is also to be noted that in successful experiments the apparatus has been as simple as possible There should be, theoretically, no limit to the drying by phosphorus pentoxide at the ordinary temperature The maximum drying in a gas is said to be attained in two years (Bone) For liquids, as might be expected, the drying is much slower Judging by the boiling point of benzene, its rise in ten years was 38°, in seventeen years it is 56°, and even now the process is probably not complete

Dr Smith gives a good account of the various theories which have been advanced to account for the influence of extremely minute traces of water vapour Prof H E Armstrong, the *doyen* of British chemists, without whose encouragement one at least of the 'dry' chemists would have done little, was the first in the field with the theory of reversed electrolysis Others, ignoring the theory of probabilities, assume in ordinary actions a linking of water vapour with the reacting gases Smits, of Amsterdam, one of the most persevering and indefatigable workers, has published a theory based on his well known theory of allotropy Sir J J Thomson's theory, published in 1894, extended to include the precipitation of water vapour on ions, seems to me to explain all the facts, if one can conceive of a liquid drop of water persisting when surrounded by at least a million other molecules

With the limitations mentioned, the book may be recommended to students, but they would be wise, if, before beginning experimental work, they read a lecture by Sir Arthur Rucker, published in the *Journal of the Chemical Society* in 1888, and two papers on manipulation in the same journal for 1929

H B Baker

Reactions of the Nerve Cell to Injury

Degeneration and Regeneration of the Nervous System By Prof S Ramón y Cajal Translated and edited by Dr Raoul M May In 2 volumes Vol 1 Pp xx + 396 Vol 2 Pp viii + 397 769 (London Oxford University Press, 1928) 50s net

HIGH in the achievements of modern Spain must be ranked the development of a school of biological science which evolved from the work of the Madrid histologist, Prof Ramón y Cajal His perfections of the silver impregnation of nerve fibres so that their axis cylinder (or essential conducting element) could be revealed to microscopical observation, led to a long series of researches on the structure of the nervous system from about 1890 to the present time

Prominent in these researches are those devoted to the study of degenerative and regenerative processes in the nervous system, and while many of the main conclusions and methods had become known outside Spain, yet the multitudinous detail, the wealth of experiment and deduction, remained, at any rate to most English-speaking histologists, unknown There were several reasons for this, of which the more apparent are their publication in Spanish in journals enjoying small circulation,

and the publication of a limited number of copies of a work on the subject in Spanish, close before the outbreak of the War. The two volumes under review are the first English translation of this work.

The controversies over the polygenist and monogenist doctrines which took place in the first decade of this century have now only an historical interest. Nevertheless, the accumulated evidence collected in the first volume of this work not only provides a lasting memorial to the virile championship and establishment of the monogenist doctrine, but also is invaluable for all future work bearing on this subject. With a wealth of detail of fine critical microscopy, Prof. Cajal traced the replacement of damaged nerve fibre separated from its cell of origin. The detail of the process is so complex, the vagrancies of the wandering amœboid growing terminal so varied and multiple, that their unfolding and rationalisation by systematic experiment, clear cut and boldly planned, is a fascinating study.

The work of Ross Harrison in America still remains the crucial demonstration of the independence of the axis cylinder process, but the essential symbiosis of these two elements in their biological partnership depends for its illustration and proof on the findings of Cajal. Of the various hypotheses put forward to explain the re-establishment of conducting paths by regeneration, he comes now to favour a combination of the established attraction of the proliferated cell of Schwann, and the attraction of the end organ itself, to explain on one hand the obvious attraction that degenerated nerve has for regenerating processes, and on the other the occurrence of regeneration when no degenerated segment delineates the path of growth. These studies of the growing point of nerve fibres and its reactions appear to offer insuperable obstacles to any other explanation.

The second volume, dealing with the reaction of the nerve centre to injury, is, like the first volume, but even to a greater extent, a mine of information for all engaged on the physiology and pathology of the nervous system. It is only necessary, for example, to indicate the bearing of the complexity of collateral formation in neurones under "regenerative turgescence", on recent work by authors who, unmindful of these complexities of the subject, have adduced experiments on the dorsal nerve roots in support of efferent fibres (parasympathetic) in these roots. This exposition of the work of Prof. Ramón y Cajal and his school on the dorsal-root ganglion cells throws considerable doubt on the widely accepted physiological hypotheses built round the pericellular plexuses of these cells described by Dogiel.

Outstanding features of the second volume are the description of the phenomena of degeneration in the cerebral and cerebellar cortex following interruption of the axis cylinder processes. The hypertrophy of collaterals and the atrophy of the damaged axon are of great significance both physiologically and pathologically. Cajal reaffirms his belief in the lack of regeneration in the central nervous system, although he adduces the experiments of Tello to show this lack is not in the neurone, but in the absence of Schwann's cell.

At the end of most of the chapters an additional note has been added summarising work which has appeared since the publication of the Spanish edition. These notes in most part fulfil their purpose, but one could wish that the chapter on neuroglia and its reactions had included the recent work of del Hortega, and that on the cerebellum, the work of Cajal himself on the newer silver methods for studying this cortex.

The book is admirably produced and includes a very large number of excellent illustrations portraying the wonderful contrasted effects which only the reduced silver method can produce. The translation is perhaps in some few places too literal to read comfortably, but is always intelligible. In three places "afferent" is used where "efferent" is evidently intended (p. 269, l. 3, p. 271, l. 7, p. 272, l. 7), and "sensory" is obviously intended for "motor" on p. 272, l. 29, and the reviewer would also suggest that Nissl "granules" is more common usage in English that Nissl "grumes".

Allen's Commercial Organic Analysis: a Treatise on the Properties, Modes of Analysis, and Proximate Analytical Examination of the Various Organic Chemicals and Products Employed in the Arts, Manufactures, Medicine, etc., with Concise Methods for the Detection and Estimation of their Impurities, Adulterations, and Products of Decomposition. Vol. 7: *The Vegetable Alkaloids.* By the Editor, and the following Contributors: F. H. Carr, Oliver Chick, Norman Evers, J. J. Fox, T. A. Henry, P. J. Sageman, T. M. Sharpe, F. O. Taylor, R. W. Tonkin, and R. Whymper. Editor: C. Ainsworth Mitchell. Fifth Edition, Revised and Partly Rewritten. Pp. xi + 869. (London: J. and A. Churchill, 1929.) 30s.

THE editor of this volume can rightly claim that it is a complete thesis on the analysis of the vegetable alkaloids. It shows improvement over the previous edition for reference purposes, as all the material

on this important section of organic chemistry is now collected and classified in one book, which includes the subject matter from Vol 6 of the last edition on alkaloids generally, and on the volatile bases of vegetable origin, as well as the subject matter from Vol 7 on the vegetable alkaloids Special sections, arranged alphabetically, owing to the difficulty of chemical classification, are given to products of definite commercial importance in connexion with food and drugs (for example, caffeine, cocaine, nicotine, opium, etc , receive separate treatment) The other known alkaloids are systematically dealt with in a general introduction, again with alphabetical grouping In the introduction the reactions and properties of the vegetable alkaloids as a group are also reviewed

In contrast with the ordinary text-book, the drafting of a comprehensive technical thesis of this nature, with its great mass of specialised information, requires the assistance of many experts to make the venture a success As a result, we find each section written by a specialist in that particular field The whole work is ably edited by Mr C A Mitchell, who also contributes the chapter on strychnos alkaloids

There is lack of complete uniformity in the revision of material from the various editions of the British and foreign pharmacopœias, in some instances the latest data are not given, and there is want of agreement between the statements recorded A number of typographical errors have also been noted, and in a few instances information that would be expected in such a volume has not been found These slips and omissions, however, are probably not more than might be expected in a work of this nature The book, which is printed in the United States, is excellently produced with regard to paper, type, and binding J Reilly

The British Journal Photographic Almanac and Photographer's Daily Companion, with which is incorporated The Year Book of Photography and Amateurs' Guide and The Photographic Annual, 1930 Edited by George E Brown Pp 784 + 64 plates (London Henry Greenwood and Co , Ltd , 1930) 2s net

This welcome annual (for it is in no sense an almanac) again makes its appearance The general arrangement is very much the same as heretofore As this is the twenty fifth year in which the present editor has had the arranging of it, the article which he contributes consists of his personal reminiscences (or some of them), which will be read with much interest But we think that he has overstepped the mark to the detriment of the memory of Sir William Abney in stating that his various text-books display a pronounced disinclination to deal with the work of other investigators, and that therefore we have in English no comprehensive work similar to those of Eder in Germany and Fabre in France Abney never attempted such a comprehensive work, although the editor states that "he was the one man to supervise" it, and perhaps the editor himself gives the reason when he says that "it was an obvious effort to him to present a subject in simple terms" If Great Britain "suffered from the Abney predominance", as stated here, that surely was the fault of his contemporaries, as this is a free country

The volume includes the many items that we are accustomed to find in it, tables, formulæ, lists of addresses, new apparatus, and so on, and excellently reproduced gravure copies of photographs

Essentials of General Physiology By Prof Eric Ponder Pp viii + 497 (New York, London and Toronto Longmans, Green and Co , Ltd , 1929) 15s net

This is a sound and clearly written text book which should prove useful to students beginning physiology The opening chapters, of an introductory character, are advisedly concerned with a plain description of surface phenomena, colloids, permeability, dissociation, and the action of enzymes, the student may already be conversant with these aspects of physical chemistry, but his interest will be maintained by the well chosen biological examples Equipped with these elements of physical chemistry, the reader is better able to appreciate the actual physical and chemical basis of the processes underlying vital phenomena

The contraction of muscle, conduction in nerve, secretion, tropisms, digestion, respiration, and circulation are the branches selected by the author for treatment from the physico chemical point of view With the rapid and many sided development of physiology, the subject is becoming so unwieldy that, if it is to be approached from a scientific point of view, there will have to be a complete inversion of the present order of study, this book constitutes a step in the right direction, since a grasp of the underlying general principles should precede a descriptive study of the phenomena of the usual human and mammalian physiology As the book is intended mainly for beginners, perhaps more illustrations might be of value, this, however, is not a serious deficiency since the text is so lucid

Les paysages catalans leurs aspects, leur structure et leur évolution Par Marcel Chevalier (Aspects physiographiques de l'Espagne) Pp vi + 172 + 48 planches (Paris Albert Blanchard, 1929) 30 francs

There is comparatively little material available on the details of the geography of the Iberian peninsula This study of the north eastern corner of Spain is therefore welcome, although the author has dealt with little outside the purely physical aspects Apart from the comparatively recent plains, M Chevalier recognises three structural divisions in the mountains of Catalonia The Pyrenees in the north with their exposures of ancient crystalline and palæozoic rocks, then the sierras of secondary and tertiary rocks of a newer topography with no evidence of glacial action, and then, lastly, the worn-down remnants of old Hercynian foldings Structure and surface features are fully discussed There are many illustrations and sketch maps The book is an enlarged edition of a volume in Catalan that appeared recently

Letters to the Editor

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

Hydrogen-like Spectra of Lithium and Beryllium in the Extreme Ultra-violet

IN preceding communications (NATURE, Nov 2, 1929, and *Comptes rendus*, Jan 1930) we have given a brief account of the extension of the extreme ultra violet down to 100 resp 88 A in the spectrum of doubly ionised beryllium (Be III) Using a vacuum spark with a considerably increased capacity and ionisation power, it has now been possible to record the strongest radiations in the hydrogen like spectra of completely ionised lithium (Li III) and beryllium (Be IV), thus extending optical spectra to 76 A

According to the Bohr theory, a system consisting of a nucleus with the positive charge e Z and a single electron will emit radiations with the following wave numbers (neglecting the slight correction for relativity)

$$\nu = Z^2 R\left(\frac{1}{n^2} - \frac{1}{m^2}\right) \text{ cm}^{-1},$$

the Rydberg constant R being slightly dependent on the mass M of the nucleus Thus,

$$R_M = R_\infty \frac{M}{m+M}, \text{ where } m = \text{the mass of the electron}$$

Using Paschen's value for the Rydberg constant (Paschen Götze, 'Seriengesetze der Linien spektren", Berlin, 1922) we obtain

$M_H = 1\ 008$	$R_H = 109\ 677\ 7$ cm $^{-1}$
$M_{He} = 4\ 0$	$R_{He} = 109\ 722\ 1$,,
$M_{Li} = 6\ 9$	$R_{Li} = 109\ 728\ 6$,,
$M_{Be} = 9\ 1$	$R_{Be} = 109\ 730\ 6$,,
	$R_\infty = 109\ 737\ 1$,,

The above relation gives for the spectrum of hydrogen the Paschen Ritz series for $n = 3$, the Balmer series for $n = 2$, and the Lyman series for $n = 1$ The calculated wave lengths of the first lines in the Lyman series are shown below Several lines of this series have been found by Lyman, Hopfield, and others

In the corresponding series of singly ionised helium (He II) Lyman found the first two members (*Astrophys Jour*, 60, p 1, 1924)

Book Prices and Reading

"THE first of those 'little books on great subjects' is considerably shorter than the other two and costs five times as much [2s 6d] it cannot be regarded as over priced, it is rather the others that are extra ordinarily cheap" One of the others is a Benn 6d, "Earthquakes and Volcanoes", by Prof Gregory I think of the story told long ago of Lant Carpenter lecturing at the 'Vic' When gas came off but slowly, as 'water' was electrolysed upon the screen, a galleryite was heard to remark to his dissatisfied companion "Well, Bill, you can't 'spect to 'av many bubbles for a a'penny" What can't you now get for 6d from either Benn or Woolworth?

I have quoted from "Our Bookshelf", in NATURE of Jan 4 On previous pages I see books are noticed priced at 18s, 21s and 14s How can students afford to buy at such prices? They simply do not and do not read, they only use cram books As a consequence, Principal Tizard complains that young 'researchers' are uncultured, having read nothing, they also cannot write There seems to be a conspiracy of publishers to repress authorship A couple of years ago, a book of mine appeared of which I can say—adopting the Shavian principle that self praise is the only recommendation—that it was dear at 8s but at 7s 6d, the price at which the publisher led me to believe that it would be issued, it was as well worth a student having as any Shavian romance up to 10s, if only for the dedication, it was issued at 15s and killed Is it worth the publishers' while to kill at 15s when they might maintain in healthy activity at half the price? Prof Bone's Vol 3 on "Combustion" costs two guineas How can we poor chemists study our future fate at such price?

What is going to be the effect upon the writing and upon the sale of real books, upon reading, of Benn's pemmican—or shall we say, 'Bennican'? Mayhap the jam is spread too thickly upon the bread Or will it be, that, soon, the volumes will be issued with an insurance ticket—against more open reading?

To day you do not get any discount on your shilling Scientific journals, especially German, are sold at prohibitive prices Reading is not merely a disappearing art but becoming impossible no one can read in a library, the more as you must not mark the margins, let alone follow Darwin's good example and tear out the few pages that are of worth In addition, wireless is fast making headway as a reading soft option I know of two very distinguished men who formerly read omnivorously o' evenings now they just 'listen in' My daughter writes, that, on the Pacific coast, the theatre is deserted, because the effort of listening and attending to the play is too much for the boys—'the pictures' have reduced them to mental somnolency Why was not the recent London Opera Festival properly supported by the public? The performances were more than interesting Was not the price too high? Art lovers are as poor as are artists Is science, as wireless, in the hands of a few, to kill the intelligence of the many?

Into whose pocket is the book money going? Sir Ernest Benn is a great exponent of economics—has he at all fully studied the intimate economics of the bookshelf? The policy of failing to encourage good books, other than those written by popular favourites or shockers? He might well call, say, Marie Stopes, Mr Wells, the author of "All Quiet", into conference It would be interesting to hear from him what his Woolworth series is doing It is a fine effort

Truth is being withheld from the public—we only play with it Take biblical criticism Is it not *our duty* to present its results dispassionately, in clear readable form, even to the young? We seem now to be agreed that the mysteries of sex shall be displayed to the adolescent We are still afraid openly to discuss the foundations of the faith that is forced upon so many

Chemistry is in dire need of critical discussion we have not a single work that is broadly critical A recent Americanistic attempt is not encouraging The astronomers seem to be sailing close to the wind—when the fifth and other dimensions come along anything may happen we may then have what my Sunday paper calls 'gaudy incarnations of common vanity, day dreams *ad lib*' figuring as science

Our present treatment of books threatens to be a very serious hindrance to the development of habits of sound scientific thought, indeed of scientific progress Naughty ones seem to sell, whatever the price, nice ones do not Are we all to be forced to be naughty, only nice in a dim background?

HENRY E ARMSTRONG

Flint Implements of Upper Palæolithic Types from Glacial Deposits in Norfolk and Yorkshire

MY researches in East Anglia have demonstrated that palæolithic flint implements occur in the glacial Boulder Clays of this region, and that these deposits, and their contained artefacts, are of widely differing ages Thus, in the Tills overlying the Cromer Forest Bed of Norfolk, have been discovered specimens of Chellean type,[1] while, in what I term the Upper Chalky Boulder Clay of Suffolk, which appears to be separated from the Cromer Tills by a series of sands, gravels, and brick earths, I have found specimens referable to Late Acheulean and to Early Mousterian times[2] Upon the surface of the Upper Chalky Boulder Clay in the Ipswich district are situated, at certain places, two superposed and ancient occupation levels yielding implements of Upper Mousterian and of Aurignacian types, and these floors are covered by a considerable thickness of hill wash which, some years ago, I correlated with the latest glacial conditions obtaining in Suffolk[3]

Recently, during a research carried out under a grant from the Percy Sladen Memorial Fund, I have discovered, *in situ*, in the Brown Boulder Clay, and associated glacial deposits of the Hunstanton district in north west Norfolk, a number of flint implements of Upper Palæolithic types These specimens, which comprise blade scrapers, *burins*, or graving tools, cores, and flakes of various sizes, are to be referred to either the Aurignacian or to the Magdalenian epoch The artefacts lie at varying depths in the deposit, which is often rich in erratic rocks, and a number of them exhibit definite striations The Brown Boulder Clay is fully described in the Geological Survey memoirs[4] dealing with the area examined, and the sections from which I have recovered my specimens are classed by the surveyors as of glacial origin It is, however, necessary to point out that, while in the memoirs mentioned, the possibility, from a geological point of view, of the Brown Boulder Clay being of later date than the chalky variety of the district is suggested, no decision upon this important matter was reached by those who conducted the survey in north west Norfolk My researches, nevertheless, lead me to believe that the

Brown Boulder Clay, judging from the artefacts it contains, is clearly later than the chalky form

Further, the discoveries in north west Norfolk (which are to be described before the Society of Antiquaries on April 3 next) support, very strongly, the conclusions I had come to regarding the glacial origin of the hill wash overlying the floors, above mentioned, in the Ipswich district

Following upon the initial stages of my work in Norfolk, Mr J P T Burchell has carried out researches in Yorkshire, which confirm, in a striking manner, the archæological results obtained by me farther south, and it now seems possible to form an accurate and complete picture of the relationship of the various palæolithic industries to the glacial deposits of England

J REID MOIR

FOLLOWING upon Mr Reid Moir's notification to me that he had discovered flint implements of Upper Palæolithic types, at the base of, and scattered throughout, the uppermost Boulder Clay of north west Norfolk in the neighbourhood of Hunstanton, I determined to conduct similar investigations in a locality situated considerably farther northward The area I chose for examination comprised the intensely glaciated districts of Holderness and Flamborough Head in Yorkshire Detailed descriptions of the glacial deposits of these two localities occur both in Geological Survey Memoirs[5] and papers and books by Carvill Lewis, Dakyns, Lamplugh, Kendall, and others[6]

The researches, which I carried out under a grant from the Percy Sladen Memorial Fund and the Society of Antiquaries, resulted in the discovery, *in situ*, of a considerable number of flint implements of Upper Palæolithic types at the base of the uppermost Boulder Clay of the area This deposit contains an abundance of erratics, largely consisting of North British and Scottish rocks Similar implements I found scattered freely throughout this Boulder Clay, many of which show marked striations This industry, which consists, for the most part, of flake implements struck from tortoise cores, I would refer to Upper Mousterian Aurignacian times The specimens comprise hand axes, scrapers, gravers, blades, knives, and tortoise cores both struck and unstruck This discovery, which indicates a complete deglaciation of Holderness and Flamborough Head during the Pleistocene period, is of particular interest in view of Prof J K Charlesworth's paper of September last,[7] in which it is postulated that the terminal moraine which builds a gravel ridge on Flamborough Head and is traceable through Holderness to its south easternmost portion (the Cromer ridge) is Magdalenian in date That the moraine in question is earlier than the St Acheul period can be proved both on archæological and geological grounds

On the Correct Formulation of Pauli's Exclusion Principle

PAULI'S 'Exclusion Principle' applied to the simplest case of the two electron or two proton system (helium atom, hydrogen molecule) is usually stated as follows if the electrons (or protons) are parallel, that is, if their spins point in the same direction, their eigenfunction must be antisymmetrical with respect to the co ordinates, if the electrons (or protons) are antiparallel, that is, pointing in opposite directions, their eigenfunction must be symmetrical

I wish to point out that this formulation of Pauli's principle is erroneous There is actually no direct relation between the symmetry character of the eigenfunctions (as functions of the co ordinates alone) and the orientations of the electrons (or protons) In every stationary state of a single electron with a given energy E, *both* orientations are in general possible, although they have different probabilities (in the same way as the different values of the co ordinates) In Pauli's theory of the spinning electron (*Zs f Phys*, **43**, p 601, 1927) these probabilities can be defined by means of two eigenfunctions $\psi_\alpha(x, y, z)$ and $\psi_\beta(x, y, z)$ which are the solutions of a system of two simultaneous differential equations

$$H_{\alpha\alpha}\psi_\alpha + H_{\alpha\beta}\psi_\beta = E\psi_\alpha, \quad H_{\beta\alpha}\psi_\alpha + H_{\beta\beta}\psi_\beta = E\psi_\beta$$

replacing Schrodinger's 'scalar' equation $H\psi = E\psi$ To every eigenvalue, that is energy level, E_μ, of the latter there correspond *two* energy levels of the former, E_μ^+ and E_μ^- with the eigenfunction couples ψ_α^+, ψ_β^+ and ψ_α^-, ψ_β^- respectively, $\int|\psi_\alpha^+|^2dv$ being the probability of one and $\int|\psi_\beta^+|^2dv$ of the other orientation

In the limiting case of a very strong magnetic field one gets $\psi_\beta^+ = \psi_\alpha^- = 0$,—whence the confusion between the type of orientation (α, β) and the character of the stationary state ($\pm$) As a matter of fact, these are quite different notions, the $\pm$ character of the state in question corresponding to the two possible values of the fourth (inner) quantum number, introduced by Sommerfeld and Pauli for the complete specification of the electronic orbits

Now Pauli's principle (in its original corpuscular form) requires that there should not be in the same atom two or more electrons with the same values of all the four quantum numbers This does not, however, imply—except in the case of a very strong magnetic field—that two electrons (or protons) with identical orbits should have opposite orientations

The wave mechanical formulation of Pauli's principle due to Dirac, amounts to a restriction to functions which are antisymmetrical with respect to variable quadruples x, y, z, σ for different electrons, σ denotes the spin variable taking two values, $+\frac{1}{2}$ and $-\frac{1}{2}$, say, for α and β respectively (and being interpreted as the projection of the spin moment in $h/2\pi$ units on one of the co ordinate axes) Thus in the case of n electrons a wave function $\psi(x_1, y_1, z_1\ \sigma_1, \quad , x_n, y_n, z_n, \sigma_n)$ for a given stationary state represents actually a complex of $2n$ functions of the co ordinates alone, corresponding to all possible (but in general not equally probable) orientation types of all the electrons with the same energy These functions need not, of course, be antisymmetrical with respect to the co ordinates of the different electrons

In the simplest case of two electrons which, taken separately, are specified by the eigenfunctions (or rather eigenfunction couples) $\psi(r_1, \sigma_1)$ and $\phi(r_2, \sigma_2)$ (r standing for x, y, z), the stationary state admitted by Pauli's principle is described in the first approximation by the function (or function quadruple) $\frac{1}{\sqrt{2}}[\psi(r_1, \sigma_1)\phi(r_2, \sigma_2) - \psi(r_2, \sigma_2)\phi(r_1, \sigma_1)]$ Taking for ψ and ϕ the two functions $\psi^\pm$ and $\phi^\pm$ considered above, we get *four* stationary states if ψ and ϕ correspond to different orbits (in Schrödinger's sense), and only *one* state in the opposite case, with definite probabilities both for the antiparallel and parallel spins

In Dirac's theory of the electron each state is specified not by two but by four functions, two of them (ψ_α, ψ_β, say) being large and the other two (ψ_γ, ψ_δ) small This can be interpreted by introducing along with

the two real eigenvalues of the electron's magnetic moment (or rather its projection on a given axis) $\pm\frac{he}{4\pi mc}$, two *imaginary* eigenvalues $\pm\sqrt{-1}\frac{he}{4\pi mc}$, which can be easily shown to correspond to two real values of the *electric* moment (or its projection) associated with the electron's spin (the electric moment in the corpuscular interpretation is equal to the magnetic one multiplied by $\sqrt{-1}$) The smallness of ψ_γ, ψ_δ with respect to ψ_α, ψ_β corresponds to the fact that the real part of the electric moment is equal to that of the magnetic one multiplied by v/c, v being the electron's velocity and c that of light

Leningrad, Dec 30, 1929

Rate of Vaporisation and Vapour Pressure A Method of Measuring the Specific Area of a Surface

LANGMUIR (*Phys Rev*, 2, 329, 1913) has developed a method for the determination of the vapour pressure of metals from measurements of the rate of vaporisation of metallic filaments *in vacuo* The vapour pressure is calculated from the Knudsen equation,

$$p = m\sqrt{\frac{2\pi RT}{M}} \qquad (1)$$

where m is the rate of evaporation *in vacuo*, after making the assumption, which Langmuir supports with a considerable amount of experimental data, that the accommodation coefficient is unity In this way he determined the vapour pressure at high temperatures, first of tungsten (loc cit) and later, with other workers, of platinum, molybdenum, silver, gold, copper, and nickel (Jones, Langmuir, and Mackay, *ibid*, 30, 201, 1927)

In order to determine the rate of vaporisation from unit area of the filament, Langmuir also assumes tacitly that the specific area of a metal surface is equal to the apparent area This assumption is, however, in general, not justifiable for irregularities of atomic dimensions are present to a greater or lesser extent in all surfaces (See Bowden and Rideal, *P R S*, A, 120, 80, 1928 Zwicky, *Proc Nat Acad Sci*, 15, 253, 1929 Constable, *P R S*, A, 119, 196, 1928) The work of Bowden and Rideal demonstrates that the specific area in suitable circumstances may be many times greater than the apparent area

The error involved in the vapour pressure measurements from this assumption may be calculated quite easily Let m' equal the measured rate of vaporisation from unit 'apparent' area then

$$p' = Km',$$

where K is a constant given by (1) and p' is the vapour pressure as determined by Langmuir Now if A is the ratio between the specific and apparent areas, the true rate of vaporisation from unit specific area is m'/A, and the true vapour pressure p is given by

$$p = \frac{Km'}{A},$$

that is

$$p' = Ap$$

The values of the vapour pressure determined by Langmuir's method will, therefore, be too large by a factor equal to A Further, the values of the chemical constants calculated from Langmuir's data appear to show that at least in the case of tungsten and molybdenum this correcting factor may be quite large, for the deviations from the theoretical chemical constant are $+1\ 40 \pm 0\ 50$ for tungsten, $+3\ 02 \pm 0\ 50$ for molybdenum, and $-0\ 25 \pm 0\ 40$ for platinum *If* these deviations are to be attributed *exclusively* to the factor A, it would appear that while in the case of platinum the specific and apparent areas are approximately equal, in the case of tungsten the former is approximately five times the latter, and in the case of molybdenum twenty times For the determination of the vapour pressure from the rates of vaporisation it is, therefore, necessary to know A accurately It is important to note that A is a measure of the area accessible to condensing molecules of the vaporising solid This is likely to be very different from the value of A determined, for example, by the method of Bowden and Rideal, which measures the area of a surface accessible to hydrogen ions

We have so far been concerned with the possibility of the determination of the vapour pressure from the rate of vaporisation, given that A is known It is quite clear, however, that the converse can be carried out that is, knowing the true vapour pressure and the rate of vaporisation to determine A, since A is simply the ratio p'/p of the vapour pressure p' calculated from the rate of vaporisation to the true vapour pressure p Moreover, since the true vapour pressure p can be measured accurately by some equilibrium method, such as the Knudsen effusion method, and p' can often be determined accurately from the rates of vaporisation, we have a fairly exact method for measuring A which is capable of extended application

The Classification of the Primates

MR TATE REGAN's letter in NATURE of Jan 25 on the classification of the Primates, with special reference to the microstructure of the dental enamel, again raises the vexed question of Primate phylogeny Attention has lately been redirected to this problem by the reiteration of the 'unorthodox' opinions of two eminent anatomists, H F Osborn and F Wood Jones

A consideration of the conflicting points of view regarding the origin of the human stem will, I think, reveal that there are two sources of confusion which tend to prevent a lucid survey of the problem, (1) an arbitrary use of the conception of irreversibility of evolution, and (2) the careless employment of a nomenclature which is often insufficiently defined

As regards the first point, it is to be noted that, in the absence of an abundant palæontological record, the construction of a phylogenetic tree must depend almost entirely upon a study of comparative anatomy, with a proper appreciation of the distinction between primitive or generalised, and specialised anatomical characters If, in the interpretation of the anatomical data, reliance is placed on the 'law' of irreversibility of evolution, it is possible, by a sort of theoretical triangulation, to infer the nature of the common ancestor of the existing members of a natural group But if the 'law' of irreversibility be accepted at all as a basis for argument, it should be carried to its logical conclusion unless strong evidence to the contrary is forthcoming in exceptional cases Further, if *all* the available anatomical evidence is taken into account, such lines of argument will inevitably lead to the conclusion that the Catarrhines cannot have been derived from the Lemuriformes (Lemuroidea of Mr Tate Regan)—as the 'Lemuriformes' are commonly defined, nor can the Platyrrhines have been derived from the Tarsioidea—as the 'Tarsioidea' are commonly defined

In regard to the second point, the adoption of a

loose terminology in some expositions of man's evolutionary origin has evidently been the cause of much profitless controversy Terms such as 'gorilloid', 'anthropoid', 'tarsioid', and 'lemuroid', are constantly being used by different authors with different connotations It is not permissible, for example, to talk of the 'gorilloid heritage' of man, for the term 'gorilloid', unless specifically defined otherwise, can only be interpreted as an adjectival form of the word 'gorilla' which refers to an anthropoid ape with specialisations such as few anatomists can believe to have been features of the precursor of the human stem The term 'anthropoid ape', also, by its common definition, implies an arboreal animal showing certain adaptive specialisations which would presumably be absent from any form ancestral to man Unless, therefore, the term 'anthropoid ape' be given a wider application than it is usually accorded, it is highly questionable whether it is legitimate to say that man has ever evolved from a form which can be strictly called an anthropoid ape Opponents of the theory of the 'anthropoid' origin of man may, in this case, be justified in their criticisms even though they may be derided for basing the latter on what appears to be a verbal quibble Similar criticisms apply to the terms 'lemuroid' and 'tarsioid'

As Mr Tate Regan implies, the interpretation of the available data in regard to the classification of the Primates is a matter of great difficulty, and largely depends upon the taxonomic value accorded to different anatomical characters by different authorities But the problem is rendered the more difficult by the lack of a precise definition of the nomenclature commonly employed in its discussion

A Relation between Ultra-violet Absorption Spectra and Heats of Combustion

THE ethylene linkage in the aliphatic hydrocarbons is characterised by two ultra violet bands, an intense one 1800 1900 A, and one of low intensity between 2200 and 2600 A (Stark et al, *Jahr Rad*, 10, 139, Luthy, *Zeit Phys Chem*, 107, 285, Carr, *J Am Chem Soc*, 51, 3041) The thermal equivalents ($Nh\nu$) of the two middle positions are 154 0 and 118 8 Kcal and the difference is 35 2 Kcal, this is almost identical with the difference in heats of combustion between a saturated hydrocarbon and the corresponding olefine, which for the first five members of the series is 36 8, 36 1, 36 2, 39 9, 37 2 Kcal (Kharasch, *Bur Stand Jour Research*, 2, 359) The average value for the thermochemical characteristic of the C C and C H linkage in the liquid state is 52 1 Kcal The heat of combustion of an hydrocarbon (liquid state) containing m double bonds can be represented by

$$Q - (3n + 1)52\ 1 - m(Nh\nu_2 - Nh\nu_1)$$

where ν_1 and ν_2 are the centres of the absorption bands For example, Q, calculated from Stark's data for diallyl, is 926 7 Kcal, experimental, 921 1

The only spectral measurements of acetylene hydrocarbons for which thermal data are available are those of Henri for acetylene and Stark and Lipp for acetylene and dipropargyl which are summarised as follows

	λ max	$\Delta Nh\nu$	$Q_1 - Q_2$
HC≡CH	2631		
	2040	31 4	60 1 = 2 × 30 0
$(HC{\equiv}C-CH_2-)_2$	2450		
	2010	25 5	114 4 = 4 × 28 6

The general formula would be

$$Q - (3n + 1)52\ 1 - 2m(Nh\nu_2 - Nh\nu_1)$$

where m is the number of triple bonds in the molecule

On the assumption that the band in the short ultra violet is related to the activation energy of the C − C or C − H linkage, calculations were made for the aliphatic alcohols In ethyl alcohol Leifson (*Astrophys Jour*, 63, 73) found six equally spaced bands between 2039 and 1892 A with the centre at 1952 A For alcohols in a homologous series the band is shifted 20 frequency units for each CH_2 (Henri's results) For the first four alcohols $\Delta Nh\nu$ (calculated from Bielecki and Henri's measurements) is 18 8, 18 3, 18 8, 20 4 Kcal, $Q_1 - Q_2$ is 37 8, 37 0, 38 3, 39 8, therefore $Q_1 - Q_2$ is equal to $2 \times \Delta Nh\nu$

By assuming for the aldehydes and ketones an analogous band near 1900 A, the value of $\Delta Nh\nu$ for seven ketones is 48 2 Kcal, $Q_1 - Q_2$ is 96 6 or 2 × 48 3, in three aldehydes $\Delta Nh\nu$ is 46 3 Kcal and $Q_1 - Q_2$ is 87 5 = 2 × 43 8 For compounds containing three different types of linkage the calculated values compared with experimental (in parenthesis) are, in Kcal allyl alcohol 435 8 (442 4), croton aldehyde 537 7 (542 1), mesityl oxide 844 3 (846 7), allyl acetone 869 0 (856 7), citral 1439 3 (1437 0)

A more extended treatment together with the theoretical interpretation of the relationship will appear shortly elsewhere

Raman Effect with Optically Active Substances

IT is already known from various investigations that the different isomeric forms of organic molecules give strikingly different Raman spectra A noteworthy case is that of the cis and trans forms of dichlorethylene, which have been studied by Bonino and Brull (*Zeit fur Physik*, 58, p 194, 1929) These investigators have found that the most striking differences appear in the characteristic molecular frequencies lying in the remote infra red and made so readily accessible to observation by the Raman method

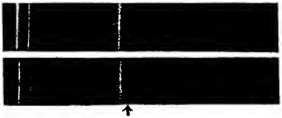

FIG 1 —Raman spectra of lævo- (upper) and dextro pinene (lower)

It is evidently of great theoretical importance to ascertain whether optical isomers, that is, the dextro and lævo rotatory forms of the same molecule, give spectra which differ in any respect To test this question, the two optically isomeric forms of pinene were examined The materials as supplied by Kahlbaum were carefully purified by fractionating at constant boiling point (154° C) All the numerous Raman lines which appear in the scattering by the dextro isomer are also observed with the lævo form and vice versa, and in identically the same positions, as we should expect There are, however, appreciable differences in the relative *intensities* of some of the lines This is particularly conspicuous in the case of

the Raman line corresponding to an infra-red wave-length of about 74μ marked by an arrow in the photographs reproduced in Fig 1, which is conspicuous in the dextro form and scarcely visible in the lævo form This result is sufficiently surprising, and is therefore put forward with all due reserve Nevertheless, the authors feel reasonably confident of its reality

Further work has been undertaken to study other optically active substances (both fluid and crystal line) It is also proposed to investigate whether the state of polarisation of the light has any influence on the observed results

The Gibbs-Ewald Reciprocal Lattice

THE Gibbs Ewald reciprocal lattice is now of such general use in the discussion of problems in crystal physics that it seems worth while to record a simple analytical expression for its definition

The usual vector definition of the reciprocal lattice is expressed by the relations [1]

$$(\mathbf{b}_i\mathbf{a}_i) = 1 \qquad (\mathbf{b}_i\mathbf{a}_k) = 0 \qquad i \neq K,$$

where $\mathbf{a}_i$ refers to the vector defining any one of the primitive triplet of translations of the crystal lattice, and $\mathbf{b}_i$ refers in a similar way to the primitive triplet of the reciprocal lattice

I now suggest an equivalent formula of a purely analytic type Let us consider the equation

$$e^{2\pi i\sum_1^3 u_i x_i} = 1,$$

and discuss the simple case in which the x_i are the co ordinates of a point referred to orthogonal axes We now consider another space referred to similarly situated axes in which the co ordinates of a point are u_i To every point u_i in the second space, there corresponds an infinite number of planes

$$u_1x_1 + u_2x_2 + u_3x_3 = n,$$

where n is an integer The distance between any two adjacent planes is equal to $n/(u_1^2 + u_2^2 + u_3^2)$ If now we apply the law of rational indices to specify the crystallographically possible planes, we see that the values of u_i are then the co ordinates of the points of the reciprocal lattice as usually defined

For the discussion of the case of oblique axes, the tensor form of the equation is probably the simplest We write immediately

$$e^{2\pi i x_i x^i} = 1,$$

where the x_i are the covariant components of the vector x the contravariant components of which are x^i The co ordinates in the reciprocal space can then be associated directly with the covariant components of the co ordinate vector in the original space [1] In the use of the tensor form it is interesting to make use of an affine co ordinate system [2] of constants a, b, c, and angles α, β, γ, appropriate for the crystal under discussion

I hope to develop the present transformation and also the more general transformation expressed by the equation $F(x_i x^i) = 0$ in connexion with the Fourier integral transformation previously published [3]

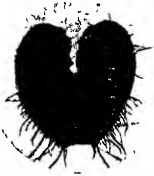
The Blowfly's Mouth

THE proboscis of the blowfly has been so often figured and described that students generally have no difficulty in understanding its structure and mode of working There is, however, one small ambiguity that beginners are liable to find somewhat perplexing, especially when only balsam preparations are used, namely, the use of the word mouth to describe the opening in the centre of the terminal disc That this opening is not the mouth in the sense of being the entrance to the pharynx is apparent when one dissects a well distended proboscis that has been cleared in potash If the disc is snipped off and examined under water without pressure (see Fig 1), the opening is



Photo] [*J Manby*
FIG 1 —Disc of blowfly's proboscis

found to be identical with the gap lying between the two lobes (*labella*), particularly with the small central region, which is nearly but not quite partitioned off from the upper part and which is continuous behind with the channel like groove in the haustellum

If the name mouth is retained for this region of the disc, the question arises what the aperture at the other end of the haustellar groove should be called Unlike the gap in the disc, this small and deeply placed aperture is concealed from view and somewhat troublesome to find unless the overlying parts be first removed When this is done—when, for example, the haustellum is cut away—the aperture is seen lying between the epi- and hypopharynx at the end of the rostrum, and since, besides being associated in this manner with appendages that are plainly oral in character, it opens directly into the front portion ("buccal cavity", Patton and Cragg) of the pharynx there seems to be good reason why it, rather than the opening in the disc, should be called the mouth

T H TAYLOR
The University,
Leeds

Organic Chemistry at University College, London

IT is now an open secret that the Academic Council of the University of London is being moved not to appoint an eminent organic chemist to succeed Prof. Robinson in the chair of organic chemistry in University College, London, but to fill the two chairs of chemistry in this institution by distinguished physical chemists The acceptance of such a fantastic proposition would disturb the balance of natural philosophical studies in University College so profoundly that immediate public protest is necessary, and the more so in that organic chemistry is not directly represented on the Academic Council

Physical chemistry is a modern subject, its achievements, based, on one hand, upon the recent rapid

developments in physics, and, on the other, upon the vast accumulation of experimental facts of inorganic and organic chemistry, have led to great advances in pure and applied chemistry But when the pure physics and the pure chemistry are removed, little is left of physical chemistry as an individual science This border line subject, indeed, could not exist without its essential props of physics and chemistry

Meanwhile, organic chemistry pours out, through its research workers, a stream of new facts far broader than that issuing from physical chemistry its problems, particularly of biological significance, are becoming more fascinating and more profound, and its experimental technique is growing in intricacy and certainty The Royal Society continues with fair regularity to elect annually one organic chemist and one from the inorganic or physical side to its fellowship, the great chemical societies, the world over, still publish many more papers on organic than on physical chemistry It is becoming increasingly more difficult to find young organic chemists to meet the ever growing needs of the research laboratories in our great industrial organisations

Until the advent of the day when the mathematical physicist shall have rendered obsolete the experimental worker in inorganic, organic, and physical chemistry, and indeed also in physics and biology, the suppression of the chair of organic chemistry in so broad a science school as that of University College, London, will be an academic disaster

W J POPE

Cambridge, Feb 8

SIR WILLIAM POPE's letter raises an issue of such importance to the future of chemistry in Great Britain that every effort should be made to place the position before the University authorities before any final and irrevocable step is taken

During the last decades of the past century the condition of organic chemistry in Great Britain was such that many of our younger chemists had to go to one or other of the great continental universities to learn the science At the present time all that is changed, and schools of organic chemical research are established in all our chief universities From these, as Sir William Pope has said, there issues a steady stream of published research comparable in quality and quantity with that emanating from any other country We must, therefore, be careful not to take any action which may set the clock back forty years and lead to a state of affairs which will again place us in the hands of the great research schools abroad

Indeed, it is almost incredible that this could now happen, although a retrograde action, such as that mentioned in Sir William Pope's letter, would undoubtedly deal a serious blow to organic science by preventing the more brilliant of the younger men from adopting a branch of chemistry which was considered in some quarters to be moribund Such a view is, moreover, so alarming that unless one had heard it expressed in conversation one would hesitate to trouble readers of NATURE by suggesting that any justification of organic chemistry is either necessary or desirable

Nevertheless, the people who have to decide these grave issues are not necessarily chemists, and a short article in NATURE dealing with the present position and prospects of organic chemistry would certainly bring enlightenment to many Advantage of the occasion might also be taken to refer to the admirable address given by the president of Section B at the recent South African meeting of the British Association I should add that I am writing this letter in my personal capacity and not as president of the Chemical Society

X-Ray Measurements with a Plane Diffraction Grating

RECENTLY Prins [1] computed the Porter correction [2] for Bearden's wave length value,[3] and found it amount to half the difference between Bearden's value and that obtained from crystal measurements, which is 0 23 per cent

1 With some necessary assumptions I have computed the same correction to 0 0007 per cent for Bearden's and to 0 002 per cent for my own value,[4] which was also mentioned

2 It is to be noticed that this correction increases the difference, and that the function of the slits in these cases only is to screen off sufficiently narrow beams

3 Effects as those calculated by Fagerberg [5] also seems to have had little influence on my value Variations in the wave lengths which may depend upon such variations of the grating constant, could not be observed As already indicated in my dissertation, the variations obtained were all explainable as accidental errors in the measurements of the plates

Tanning Materials of the British Empire

By Prof. JOHN READ

THERE is much truth in the old saying that there is nothing like leather; and one rejoices that the tanner continues to thrive in an age which has produced substitutes for so many of the common commodities and witnessed the decline and extinction of so many of the ancient crafts. The exceptional calls which were made upon the leather industry during the War led to an enormous demand for tanning materials, but even under the more settled conditions of the last few years the consumption has shown a steady increase. The total value of such materials used in Great Britain in 1928 was £2,413,000, of which more than half was imported from foreign countries; this position cannot be considered satisfactory when the supplies available within the British Empire are reviewed.

The examination of tanning materials has taken an important place among the many valuable series of investigations which have been conducted at the Imperial Institute upon natural products from all parts of the Empire. In 1926 an Advisory Committee on Tanning Materials was constituted, and a recent publication[1] prepared by members of the Institute staff, affords a general account of the chief tanning materials of Empire origin, together with a useful bibliography, and statistics and graphs illustrating consumption and prices in Great Britain. The review includes materials which show promise, in addition to those which have already secured recognition; the classification is under the headings of barks, woods, leaves, fruits, tubers, and miscellaneous materials.

The chief tanning materials grown in Great Britain are oak and larch barks; the combined annual production of about 10,000 tons furnishes, however, only about 7 per cent of the total supply of tannin required for domestic industrial purposes. In spite of its slow rate of penetration into the hide and its high cost, oak bark tannin is used extensively in producing the best grades of heavy leather. The best English oak bark, grown in Hampshire and Sussex, yields 12-14 per cent of tannin, while good European samples contain 10-13 per cent. Tannin extracts are prepared on the Continent and in North America also from oak wood, which contains 5-13 per cent of tannin; moreover, the cups of the acorns of *Quercus Ægilops*, with a content of more than 30 per cent, are imported extensively from Asia Minor and Greece under the name of valonia. Within the Empire, oaks occur notably in India, Burma, and New Guinea, but it is in the last named country only that the possibility of utilising the bark or wood as a source of tannin appears to offer promise.

In 1928 the two main vegetable tanning materials used in Great Britain were quebracho (extract) and myrobalans, and these were followed closely by wattle (bark and extract) and chestnut (extract). A glance at the sources of these four materials reveals several points of much interest. Quebracho extract is imported exclusively from the Argentine, and the value of this trade has increased from £142,000 in 1913 to £669,000 in 1928. There appears to be no fundamental objection to the replacement of much of this material by Empire tannins. Myrobalans, the astringent fruits of various species of *Terminalia*, are produced extensively in India. The combined value of the fruits and extract used in Great Britain in 1928 was £381,000, and shipments of almost equal value were made from India to the United States. The pyrogallol tannin of myrobalans has a low rate of penetration and produces a spongy leather; it has consequently been blended with quebracho and other tannins with greater astringency and penetrative power. "Experiments conducted with Empire tanning materials during the War, when there was a shortage of foreign supplies, established the value of the mixed tannage of myrobalans and wattle bark. The astringent, readily penetrating wattle liquors are mellowed by the addition of myrobalans which, through natural fermentation, provide the necessary degree of acidity, and render the leather brighter in colour while diminishing its tendency to become red on exposure to light."

Wattle bark is one of the most abundant and widely used tanning materials of the Empire, and its increasing popularity has led to a careful consideration by the Imperial Institute Advisory Committee of its actual and potential sources of supply. In Australia, the native home of the wattles, there are more than four hundred indigenous species, of which the most important for commercial purposes are *Acacia pycnantha* (the 'golden wattle' of South Australia) and *A. mollissima* (the 'black wattle', a variety of *A. decurrens*). The best commercial specimens of golden wattle bark ('Adelaide bark') contain about 38 per cent of tannin, but in some instances the air-dried material yields as much as 50 per cent, so that *A. pycnantha* provides one of the richest known sources of tannin. Black wattle bark sold in the Sydney market gives an average tannin value of about 30 per cent, unless it has been mixed with the inferior bark of the silver wattle (*A. dealbata*).

At the beginning of the century, Australia enjoyed a thriving export trade in wattle bark, but in 1926–27 the total exports of tan barks (consisting largely of mallet bark from *Eucalyptus occidentalis*) amounted only to £4010. Moreover, in the same year the excess of imports over exports of tan barks reached £23,674. Australia, by virtue of its profusion of wattles, *Callitris* 'pines', eucalypts, and mangroves, possesses unrivalled natural sources of astringents; and yet the paradoxical position has arisen that the Australian leather industry is dependent upon imported tanning materials produced from Australian species of *Acacia* which have been cultivated in South Africa. The decline in the Australian industry is due to a combination of factors, such as wages, labour supply, depletion of natural forests, and lack of market for the wood.

[1] "Tanning Materials of the British Empire." Reprinted from the *Bulletin of the Imperial Institute*. London: Murray, 1929. Price 2s.

Of the total financial return from a wattle plantation in Natal, 56 per cent was derived from the sale of bark, 33 per cent from mine props, and 11 per cent from fuel Natal, which is now one of the main centres of the wattle bark industry, offers a favourable climate for the cultivation of the black wattle, and at present cheap native labour is available for stripping and handling the bark ' According to the secretary of the Wattle and Timber Growers' Association, the present value of the South African wattle industry may be assessed, at a conservative estimate, at £2,000,000 a year, of which more than half is money brought into the country by the export of bark and extract " It is therefore not surprising that the Forest Department of the South African Government has organised a comprehensive scheme of sylvicultural research, dealing with growth measurements, standard yields, optimum age, incidence and extent of insect attacks, fertilisers, etc Encouraging results have also attended the experimental cultivation of *A mollissima* and other species in Kenya Colony, Tanganyika, and India

Chestnut extract is produced mainly from the wood, which when air dried contains about 8 13 per cent of tannin The chief producing countries are France, Italy, and the United States, and of the overseas countries of the British Empire only India and Burma offer possibilities for the exploitation of species of chestnut as sources of tannin Researches carried out at the Forest Research Institute at Dehra Dun have indicated that trees from Burma yield a richer extract than the European trees, but it is doubtful whether the product could be marketed economically under the prevailing conditions

In these remarks it has been possible to comment only upon a few of the many facts, figures, and investigations finding mention in an unusually interesting publication, which, we are informed, has already been published on the continent in the form of a German translation

Research in Freshwater Biology and the Functions of a Freshwater Biological Station

By Prof F E FRITSCH

FRESHWATERS are put to many different uses Primarily they are the source of domestic water supplies, including the huge amount of water required for sanitary purposes Fresh water is, further, employed in enormous quantities in most, if not all, manufacturing processes Flowing water is increasingly used as a source of power, while many British waterways serve as a means of communication An appreciable section of the population, moreover, find relaxation in freshwater fisheries, while many a lake or stream is the centre point of a beauty spot

At the same time streams (and sometimes other kinds of waters) serve as the natural recipients of sewage, only too often incompletely purified, and of the waste effluents from a great diversity of chemical works and factories During the course of the nineteenth century the quick growth of urban populations and the rapid industrial development combined, as a consequence, to bring about a very serious state of pollution in many British rivers, with the result that fish life was appreciably diminished, and certain kinds, like salmon and trout, disappeared altogether from the more strongly polluted waters This led to the appointment of a series of Rivers Pollution Commissions, which sat from 1865 onwards, and the reports of which are classical pieces of work which gave to Great Britain a lead of thirty to forty years in water investigation Yet, since then, and particularly on the experimental side, we have been far outdistanced by other countries In the present century, and especially since the War, however, public opinion has again become alive to the evils attendant upon wholesale water pollution, and various committees have been set up to deal with the matter Among these, special mention may be made of the Standing Committee on Rivers Pollution appointed by the Ministry of Agriculture and Fisheries in 1921, and the Water Pollution Research Board established in 1927

The three non technical reports published by the former Committee (1924-26) contain abundant references both to the lack of scientific knowledge on the organic life of stream and lake and to the need for its acquisition In the second report (p 19) it is emphasised as essential that ' those responsible for the work of river regeneration should have at their disposal the fullest scientific information bearing on the subject ", whilst on p 24 the same report continues " At bottom, the problem is doubtless a question of the balance between all the different forms of animal and vegetable life under the particular environmental conditions which prevail ", and (p 12 of the third report) " it is upon the abundance and well being of these small organisms that the fish life ultimately depends "

It is, however, not merely in relation to pollution and fisheries that a complete knowledge of the biology of British freshwaters must be of paramount economic importance It is no less essential from the point of view of domestic water supplies, while ignorance on this subject is no doubt often the unrecognised cause of difficulties or deficiencies in various manufacturing processes in which water plays a considerable rôle Moreover, a biological treatment of the effluents may well become a practicable matter in certain cases Nor can it be doubted that fish-breeding would profit from a more adequate knowledge of aquatic biology

What, then, is the state of our knowledge as regards the biology of freshwaters in general and of our own in particular? Professional biologists and amateur naturalists have done much to acquaint us with the multifarious aquatic fauna and flora, but there are immense gaps in our knowledge Collecting has been carried out mostly during the warmer period of the year, and few data are available as regards

the fauna and flora during the winter months Again, the organisms that thrive in the deeper water of rivers and lakes, and especially those that inhabit the stream-bed or the lake-bottom, are, as a result of their relative inaccessibility, very imperfectly known Our ignorance in this respect is much greater on the botanical than on the zoological side A recently published account of the attached algal communities of certain British streams includes the description of a new genus and several new species, and analogous investigations in other quarters would probably afford a like result We are thus at the present time quite inadequately familiar with the organisms that occur in freshwaters, yet whose individual presence or absence may be an index of the purity of the water and the cause of important biological changes Our knowledge of the life histories, except in a very few forms, is incomplete, and in only too many cases nil

Moreover, although at present only clearly demonstrated for small ponds and for the macroplankton communities of larger waters, it is apparent that the microscopic fauna and flora exhibit a very definite annual periodicity and one, too, that varies appreciably in successive years Such variations in the amount and time of occurrence of the diverse organisms are certainly an expression of corresponding variations in the environment, and by correlating the two, a number of important hints as to the causes underlying the appearance and extent of development of the various denizens of a piece of water are to be obtained

Conclusions of this kind, however, require to be supported by experiment and by a far more comprehensive chemical and physical analysis of the environment than has hitherto been undertaken Such work would lead to results of fundamental value, not only from the purely academic point of view, but also because it would provide means of controlling to some extent the nature and degree of development of the organic life in freshwaters

Again, we possess at present but very fragmentary ideas as to the interrelationships of the diverse animal and plant communities in lake and stream Although data may be available as to the direct food of certain fish, the nature of the nutriment upon which their prey in its turn relies for sustenance is almost always unknown Birge and Juday, working on the lakes of Wisconsin, have shown the great importance of the nannoplankton which furnishes a large proportion of the available organic food Of the nature and extent of the nannoplankton in other waters, however, practically nothing is known Nor are the interrelationships of the organic communities of freshwaters merely a question of food relations

The diverse problems just indicated are not by any means the only ones awaiting solution in the realm of aquatic biology, but have been selected because they are perhaps the most obvious They are of a similar nature in many kinds of water, and a long stride will have been taken towards their solution by the selection of a typical area of freshwater for intensive investigation over a period of years For this purpose a properly equipped laboratory, with a permanent staff of scientific workers, needs to be established in the immediate vicinity of one or more suitable water-surfaces The problems are not such as can be solved by occasional visits followed by work in a university laboratory, but in practically all cases require daily observations and records made on the spot Even a water sample does not remain the same if carried some distance before analysis

The staff of such a laboratory would make it their business, not only to become acquainted with the fauna and flora all the year round, but also would undertake regular chemical and physical investigation of the water in order to correlate changes in the one with changes in the other Plentiful experimental work would be necessary in order to substantiate the conclusions thus arrived at Moreover, a detailed study of the life history of many of the organisms present would have to be undertaken, since their whereabouts and state of existence during the 'absent' period would in many cases, no doubt, prove to have a direct bearing on their time of maximum abundance An important function of such a station would further be to initiate new methods of limnological investigation and to test the efficacy of those in current use

Freshwater biological laboratories of this kind have long been in existence on the continent, among the more important being those of Plön in Germany, Lunz in Austria, and Aneboda in Sweden, all supported by public funds and growing in importance year by year While the work at such stations should primarily be of the nature of fundamental pure research, it is highly desirable that those concerned with applied problems should already, at an early stage, occupy working places in the laboratory While they may obtain considerable help from the permanent scientific staff, the latter would profit greatly from contact with the economic problems that have to be solved

It is not considered necessary to stress the scientific importance of such an institution, which was made sufficiently clear in the widely attended joint discussion between sections D and K at the Glasgow (1928) meeting of the British Association on "The Biological Investigation of British Freshwaters" An additional point to be made, however, is that a station of this kind would soon furnish a quota of limnological workers who could be drawn upon for the solution of applied problems, whilst it would stimulate work in other parts of the Empire and provide instruction in modes of attack

It is with the prime purpose of securing the establishment of such a laboratory that the Freshwater Biological Association of the British Empire (inaugurated at a meeting held in the rooms of the Linnean Society of London in June of last year) has been founded In order to arouse public interest and to initiate the raising of the necessary funds, the Council of the Association has invited all interested parties to a meeting to be held at 2 30 P M on Feb. 21 next, at Fishmongers' Hall, by kind permission of the Court of the Fishmongers' Company The chair will be taken by the Right Hon Lord Rothschild, president of the Association.

Obituary.

MAJOR P A MACMAHON, F R S

ON Christmas Day of last year, Major Percy Alexander MacMahon died at Bournemouth By his death, the science of pure mathematics has lost a distinguished devotee with a striking individuality Not that MacMahon was solely a scientific investigator He had been a soldier, he retained the title of his military rank to the end of his days He had been engaged in teaching for not a few years, his powers of exposition were marked by a clear directness that could be envied He had been a Civil Servant, for fourteen years, until his retirement in 1920 under the age limit, he was Deputy Warden of the Standards of the Board of Trade But throughout all the stages in his varied avocations, MacMahon achieved and maintained a high reputation as a pure mathematician

The outward facts of MacMahon's life may be recorded briefly Born at Malta on Sept 26, 1854, he was the second son of Brigadier General P W MacMahon His school was Cheltenham on leaving school, he went to the Royal Military Academy at Woolwich and entered the Royal Artillery in 1872 He was professionally connected with that arm for many years until he was of standing for promotion to colonelcy, but he abstained from qualifying for promotion, and he retired with the rank of major Some early years of military duty were spent in India On his return to England he was drafted into the educational side of military training He was appointed an instructor in mathematics at Woolwich in 1882 there, he was a colleague of his former teacher, Prof A G (afterwards Sir George) Greenhill, for whose powers he ever retained the highest respect Later, in 1890, he was appointed professor of physics in the Ordnance College, and from 1904 to 1920 he was attached to the Board of Trade, in the office already mentioned

Concurrently with all these successive professional occupations, MacMahon was diligently engaged in research In no long time he had established a mathematical reputation by his investigations, published in the *Quarterly Journal of Mathematics*, the *Proceedings of the London Mathematical Society*, the *American Journal of Mathematics*, and the *Proceedings of the Royal Society* Soon, a gradually growing share in the official activities of learned societies was assigned to him He was elected a fellow of the Royal Society in 1890 was president of the London Mathematical Society in 1894–96 was president of the Royal Astronomical Society in 1917 and for many years, either at intervals, or for long continuous periods, he was a member of the respective councils of those bodies He also acted as a General Secretary of the British Association for twelve years in 1914 he was appointed a Trustee while in 1901, at the meeting in Glasgow, he was president of Section A (Mathematical and Physical Science) of that body, delivering an interesting address upon the general aspects of the subjects of his own mathematical preference

The value of MacMahon's original work was widely recognised by the conferment of honours, such as academic and scientific corporations alone can worthily confer Unconnected with any university by training, he received a number of honorary degrees, he was made doctor of science by Dublin in 1897 and by Cambridge in 1904, and doctor of laws by Aberdeen and by St Andrews in 1911 It is no secret that he was all but appointed Savilian professor of geometry in the University of Oxford in succession to Sylvester, on the latter's death in 1897 In his later years, until his health broke down in 1928, when he removed to the south coast of England, he and his wife settled in Cambridge After his honorary doctorate, and by express invitation, he had joined St John's College, Cambridge, a college including in its foundation many personal friends such as the present Master (Sir Robert Scott), Sir Joseph Larmor, and Prof H F Baker, among the mathematicians

Nor were scientific honours less profuse than those of an academic quality MacMahon was elected an honorary member of the Royal Irish Academy and of the Cambridge Philosophical Society The Royal Society appointed him its representative as a governor and fellow of Winchester, and awarded him a Royal Medal in 1900 and the Sylvester Medal in 1919 The London Mathematical Society awarded him the De Morgan Medal in 1923

Thus MacMahon's military career had gradually merged into avocations connected specially with pure science and the worth of his scientific life had met with ample recognition But the real crown of his scientific life is constituted by the additions to knowledge which he achieved in the course of his mathematical investigations

MacMahon's contributions to mathematical science are contained in many separate memoirs, more than one hundred in number, and in one treatise on the grand scale, his 'Combinatory Analysis" in two volumes, published (1915, 1916) by the Cambridge University Press The development of his genius, when once he had settled into his main region of original research (and he settled early), was swift and clear, as exhibited by the sequence of topics in his memoirs regarded chronologically, and that development was maintained with a continuity which was remarkable and persistent His earliest papers were rather scattered in their subjects he dealt with isolated topics, with some properties of special curves or the integrations of some differential equations connected with elliptic functions But very soon his true line had been found thereafter, progress was steady and unhalting

His real beginning was made not later than 1883 by a simple discovery which opened up a new field of investigation and completely transformed one range of the theory of invariantive forms, created and amplified by Cayley, Sylvester, and Hermite In that theory it had long been known that any seminvariant—that is, an invariant or the leading coefficient of a covariant—of a binary quantic of quite general rank satisfies a central linear partial differential equation of the first order, which depends

solely upon the parametric coefficients of the quantic It was also a matter of established knowledge that, subject to one proviso, a symmetric function of the roots of an algebraic equation of quite general degree satisfies another linear partial differential equation of the first order, which likewise depends solely upon the parametric coefficients in the equation The limiting proviso is that the partition of the symmetric function must be non unitary that is to say, if the symmetric function of the roots $\alpha, \beta, \gamma,$ of the equation be denoted by the expression $\Sigma\alpha^p\beta^q\gamma^r$, no unit integer shall occur in the partition $p, q, r,$ of the number $p+q+r+$ which is the weight of the function

MacMahon's discovery (hailed as 'very remarkable' by Cayley) was that, by mere arithmetical changes connecting the coefficients of the quantic $(a_0, a_1, a_2, \quad)(x, 1)^n$ with the coefficients of the equation $c_0x^n + c_1x^{n-1} + c_2x^{n-2} + \quad = 0$, the critical differential equation satisfied by the seminvariants of the quantic becomes identical with the critical differential equation satisfied by the non unitary-partition symmetric functions of the roots of the equation These arithmetical changes, by which the coalescence is effected, are

$$a_0 = c_0,\ a_1 = 1!c_1,\ a_2 = 2!c_2,\ a_3 = 3!c_3,$$

The property, thus discovered, entails the consequence that seminvariants of the quantic and non-unitary partition symmetric functions of the roots of the equation are formally equivalent, if the foregoing relations hold between the two sets of coefficients For example,

$$a_0^2\Sigma\alpha^2 = a_1^2 - a_0a_2,\ 2a_0^3\Sigma\alpha^3 = -(a_0^2a_3 - 3a_0a_1a_2 + 2a_1^3),$$

$$12a_0^2\Sigma\alpha^2\beta^2 = a_0a_4 - 4a_1a_3 + 3a_2^2$$

Thus seminvariants of a quantic can be treated as non unitary partition symmetric functions of an associated ordinary algebraic equation This range of invariantive forms can therefore be constructed from the results of the pure algebra of symmetric functions, the weight of the form being the same as the weight of the function In turn, by its dependence on the non unitary partitions of the weights, this pure algebra invokes the theory of the partitions of numbers MacMahon's initial discovery thus made a link between the theory of invariants and one branch of the theory of numbers As invariants can arise through continuous variation of the magnitudes which occur, while partitions are necessarily concerned with discrete magnitudes, all the cognate work established another connexion between the calculus of continuous quantity and the calculus of discontinuous quantity

The ensuing researches had one important, almost an immediate, result Progress in the theory of covariantive forms had, to some extent, been barred through lack of a complete mastery over the syzygies, that is, the homogeneous relations among the seminvariants But owing to this new correspondence between seminvariants (or perpetuants, as Sylvester styled them) and the non unitary-partition symmetric functions of the roots of an equation, the syzygies in question were transferred to the region of the selected symmetric functions The last can be enumerated by means of the partitions, the relations, which connect them, are established by algebra of a simple character initiated by Newton and the calculations thus became matters of pure arithmetic and algebra

The way thus was indicated for a new algebraical proof of one theorem of fundamental importance—the finiteness in number of the aggregate of the asyzygetic concomitants of a binary quantic, it had previously been known only by Gordan's proof, which used the methods of umbral representation By Cayley and MacMahon, among others, especially in relation to syzygies, to generating forms, and to ground forms, the algebraic work was developed By MacMahon himself, utilising earlier researches of Sylvester and others on the partition of numbers (and, as a happy incident, securing for publication some forgotten unedited lectures of Sylvester on the subject) a full development of partitions in general, with many ramifications and amplifications, was revealed The work was (what, in another connexion, Sylvester had called) a new world of analysis

Accounts of the work, while still it was in progress, will be found (though with much self effacement) in MacMahon's presidential address to the London Mathematical Society (*Proc Lond Math Soc*, vol 28, pp 5 32, 1897) in 1896, and in his address as president of Section A at the Glasgow meeting of the British Association in 1901 (British Association Report ", pp 519 528, 1901) Memoir succeeded memoir in his consecutive development of the theory over a number of years He dealt with matters apparently so diverse as symmetric functions, differential operations and their comparative effects partitions of numbers, unipartite and multipartite, their separations and their compositions permutations, in a multitude of associations Euler's Latin squares, magic squares, ancient and modern diophantine equations and inequalities enumerating (or generating) functions, in their persistent emergence throughout the theory Finally, he produced a systematic account of all this work, including cognate investigations of other writers, in the treatise 'Combinatory Analysis ", cited earlier It is a fitting and an abiding monument to his genius

Nor did MacMahon disdain the lighter issues of his work It admitted of illustrations and applications that can appeal (though, as the world estimates pure mathematics, too seldom do appeal) to those who are unversed in mathematical phraseology and mathematical conclusions Thus he delivered an almost untechnical lecture on "Magic Squares and other Problems on a Chess-Board" as a Friday evening discourse at the Royal Institution on Feb 14, 1902 At the same place, on the afternoons of Jan 30 and Feb 7, 1907, he lectured on "Standards of Weights and Measures" His interest extended to special problems such as finding the totality of ways of seating a number of married couples at a round table dinner party, so that each lady sits between two gentlemen and no lady is next her husband He found relaxation and amusement in using the ideas of combinations and permutations for the construction of ingenious

(yet not useless) pastimes Thus, to select one instance, full sets of pieces of cardboard are required all the pieces of a single set are to be of the same shape (usually triangular, or square, or hexagonal) and of the same size they are to be coloured, each, for example, with three out of four colours, while no two are to be coloured in exactly the same way By the adoption of definite rules for combining the pieces of a set, a large number of different forms can be obtained, each such form being a geometrical pattern Each pattern can be repeated so as to provide a general symmetric design The designs can be utilised in a variety of ways for humble wall paper, for mosaics and woven fabrics, for the refined ornament of architecture In a small volume entitled "New Mathematical Pastimes", published in 1921 by the Cambridge University Press, he gave an account of these recreations, at once light and serious the contents are entirely his own creation

MacMahon's investigations extended over nearly half a century Many in number, diverse in range, they constitute a fine contribution to his science, and they assure him an honourable place among the prominent pure mathematicians of his generation

A R F

PROF T BRAILSFORD ROBERTSON

NEWS has been received of the death on Jan 25, from septic pneumonia, of Prof Brailsford Robertson, of the University of Adelaide His premature death, at the comparatively early age of forty five years removes one of the most active and valuable workers from biochemical research, and is a very serious loss to the recently instituted movement for the more rapid application of biological knowledge to the development of animal husbandry in Australia

Thorburn Brailsford Robertson was educated at the University of Adelaide In 1904, attracted by the work of the late Jacques Loeb at the University of California, he went there as a research student in biology and for several years worked in close collaboration with Loeb, and eventually succeeded him as professor of biochemistry and pharmacology at Columbia University in 1916 In 1918 he was called to the chair of biochemistry at the University of Toronto in succession to Prof A B MacCallum, and in 1920 he returned to Adelaide as professor of biochemistry and general physiology in succession to his father in law, the late Sir Edward Charles Stirling

From 1920 until the time of his death, Prof Brailford Robertson occupied a prominent position in Australian biological science, both in pure research and in the application of the results of research to industrial problems He was one of the founders of the *Australian Journal of Experimental Biology and Medical Science* When the Commonwealth Council for Scientific and Industrial Research was instituted a few years ago, he was invited to become the chief officer in charge of investigations on the nutrition of animals To enable him to devote the major part of his time to this work, he was relieved of teaching at the University, though he continued to be a member of the Senate, so that his experience might be available in developing the school of biochemistry and physiology at the University

Prof Robertson was an assiduous worker and a prolific writer He did most important work on the physical chemistry of the proteins, and later conducted long and laborious research on problems of growth and senescence Among the problems of general physiology to which he made valuable contributions may be mentioned allelocatalysis as a factor in the multiplication of infusoria, the permeability of cells and the underlying physico chemical principles involved in cell division In addition to numerous papers in scientific journals, he published "The Principles of Biochemistry" and other two works, namely, 'The Physical Chemistry of the Proteins" and 'The Chemical Basis of Growth and Senescence", in both of which he incorporated the results of his own original work on these subjects

Prof Robertson had a stimulating personality, and, as a lecturer, had the gift of imparting his new enthusiasm to his audience His death will be deeply regretted in scientific circles, especially in North America and Australia, in both of which continents he exercised a great influence in the development of biochemistry, both as a science and in its application to practical problems The loss of his profound scientific knowledge and great experience in organisation will be a very serious blow to the work of the Commonwealth Council for Scientific and Industrial Research

J B O

MR F P RAMSEY

THE death on Jan 19 of Frank Plumpton Ramsey at the early age of twenty six has cut short a life which bore exceptional promise of eminence in mathematics and philosophy The elder son of Arthur Stanley Ramsey, now President of Magdalene College, and the author of well known treatises upon subjects in applied mathematics, Frank Ramsey was born in 1903 and passed his boyhood in Cambridge From King's College Choir School he became first a scholar of Winchester, and then a scholar of Trinity College, Cambridge in 1923 he graduated in the first class of the Mathematical Tripos, with distinction, and in 1924 was elected to the Allen (University) Scholarship At the time of his death he held a University lectureship in the Faculty of Mathematics, and was a fellow and director of studies at King's College, Cambridge

It could not be expected that Ramsey's published work would fill a large number of pages, yet there is enough to prove the distinction of his mind and powers The London Mathematical Society has printed two weighty papers, "The Foundations of Mathematics" (1926) and "On a Problem of Formal Logic" (1929) The former, written after Ramsey had become acquainted with the work of Wittgenstein, is probably his most important original production In it he aims at presenting the general method of Whitehead and Russell in a

form free from the objections raised by German critics there can be little doubt that Ramsey would have returned to this subject and further developed it He has written on 'universals' in *Mind* (Oct 1925), and on mathematical logic in the "Encyclopædia Britannica" and elsewhere Two papers in the *Economic Journal*, on the mathematics of taxation (March 1927) and of saving (December 1928) must be mentioned, on account of the high praise bestowed upon them by economists competent to judge

This scanty list reveals the bent of Ramsey's mind As a student he proved himself a mathematician of exceptional gifts, but his interest and strength lay in the application of mathematics to problems of philosophy or economics His main interest was in the very difficult boundary region between mathematics and logic in this he was already recognised as an authority For a truer appreciation of him as a man we must turn to his contemporaries, his friends and colleagues To them, Frank Ramsey seemed to tower over his fellows intellectually even as he did physically—for he stood 6 ft 3 in or thereabout and was of unusually sturdy build What Ramsey might have achieved, how grave the loss to learning in his untimely death, they cannot tell, but the memory of a friend who combined unrivalled powers of mind with an unassuming simplicity of manner and character will remain

Ramsey married in 1925, Miss Lettice Cautley Baker, and leaves two daughters At the end of November he was attacked by influenza, the ill-effects of which persisted At length an operation was judged to be inevitable, and after it he died

---

We regret to announce the following deaths

Prof Charles Julin, member of the Belgian Royal Academy of Sciences and formerly professor of comparative anatomy in the University of Liège, known for his work on the morphology and embryology of the Tunicates, on Feb 5, aged seventy three years

Dr E D Roe, Jr, director of the observatory and for twenty nine years professor of mathematics at Syracuse University, known for his interest in pure mathematics, the testing of objectives and double stars, on Dec 11, aged seventy years

Prof Eduard Study, emeritus professor of mathematics in the University of Bonn, author of works on the geometry of dynamics, on ternary forms, spherical trigonometry, orthogonal substitution and elliptic functions, on Jan 6, aged sixty-seven years

Prof A V Vasiliev, of the Universities of Kazan and Leningrad, who was distinguished for his work on the theory of numbers and mathematical philosophy and was instrumental in establishing the Lobachevski prizes for works on non Euclidean geometry and mechanics, on Oct 6, aged seventy-six years

News and Views

Rationalisation, especially in reference to the chemical industry, was the subject of a paper by J Davidson Pratt, general manager of the Association of British Chemical Manufacturers, read at the University of Bristol on Feb 6 The general principle that exact knowledge should be the basis of industrial policy was most clearly stated and of course the principle is in practice recognised more generally in the chemical than in other industries Imperial Chemical Industries and the German I G are well known Chemistry involves so obviously the problem of research and co ordination of results that the tendency to large scale and long range thinking in the industries dependant upon a knowledge of chemistry can scarcely be resisted Mr Pratt was in fact preaching to the converted But the conversion, as he pointed out, has not gone far enough Besides the important issues with which he dealt there are others National 'rationalisation' on the basis of amalgamation or association of firms gives the group so united a great *political* influence, which in practice has been used for the introduction of protective tariffs and the maintenance of high prices within the tariff wall It is quite useless to say that the consumer should not suffer He will, unless policy prevents it, and the policy of a national amalgamation in any trade is never in favour of the consumer at home, unless competition is feared from abroad But even international agreements may be aimed only at keeping prices up

In Great Britain, however, we have still a long way to go towards standardisation and amalgamation in most industries before any danger to the consumer need be feared For example, the coal industry seems still to be thought of, even by its reformers, as a separable industrial unit But would not true rationalisation be based upon the *uses* of coal, not the mere getting of coal? Chemistry has scarcely been used by those who have controlled the policy of coal-getting They have provided productive industry and the private consumer with primitive lumps of a natural product and given no attention to research either for power supply or for by products If one may venture upon political issues, neither the Samuel Report nor the present Government's Coal Bill has envisaged the chemical connexions of coal The whole industry is pre scientific The chemists have still a large field to enter, outside what are called the chemical industries The danger, indicated but not emphasised by Mr Pratt, is that the financier and industrialist will not go far enough in the application of scientific knowledge and the promotion of research It is very tempting to 'rationalisers' to be satisfied with a collection of meaningless statistics as to existing processes or methods

Never before in the history of the world have greater or more momentous issues presented themselves in the political sphere than those which now confront us Even the greatest of all at any time, that of peace or war, though not now a direct or immediate issue, can never be far away but lurks as a sinister phantom in the background There is thus the greater need on the part of the electorate in any democracy for intelligent apprehension of the many difficult and intricate political problems which call so urgently for solution—and the political here neces-

sarily includes the economic The trouble hitherto has been that everyone feels himself competent to discuss and even to decide weighty matters in this field without knowledge or trained habits of thought Ignorance, shallowness, prejudice, and, above all, garrulity, reign supreme No wonder the scientific mind turns from politics in disgust, and this is a thousand pities, for, as we have frequently urged, there is plenty of scope for the scientific habit of close, concentrated, creative thought

AMID the vast mass of political writing and speaking which deafens and confounds the modern ear, one has to proceed with discriminating caution It will frequently be necessary to rule out and refuse to take too seriously the political diatribes of the daily Press, in view of the conditions under which these are produced The monthly reviews are sometimes helpful, but despite the profusion of our periodical literature, it yet seemed that there remained room for a monthly or quarterly review devoted solely to the political field, forming a platform for serious and well informed students of politics So far as one can tell from the first number of the new review, *The Political Quarterly*, published by Messrs Macmillan and Co, Ltd (price 3s 6d), and controlled by a very competent editorial board, it seems reasonable to hope that we have here a guide, counsellor, and perchance a friend, amid the thorny mazes of politics The first number is well balanced and contains several concisely written and authoritative articles, book reviews, and surveys of current affairs Alfred Zimmern's "Democracy and the Expert" should prove of considerable interest to men of science, who will also appreciate the attempts made to interpret the large amount of real experimental research and its results now undertaken in the social and political sphere The new review takes a progressive point of view and intends to act as a medium of constructive thought

SUBSTANTIAL progress is now being being made with the grid of 132,000 volt overhead wires which will ultimately connect together all the large and efficient electric stations in Great Britain Up to the end of last year, about sixty miles of the system had been completed, but before the end of this year there will be nearly a thousand miles of the system in operation The principal main line so far constructed extends from Greenock through Glasgow to Bonnybridge It includes high level crossings over the Cart and the Clyde and the extension to Dundee crosses the Forth and gives a clearance of 100 feet above high water level The problem of supplying consumers in small villages and farms has not yet been satisfactorily solved The 33,000 volt lines already in operation in several districts have given little trouble even during the exceptionally stormy weather that has occurred recently Straw blown from stacks has occasionally short-circuited the insulators, and the sea salt deposited on the line insulators near the coast has in a few instances caused them to flash over In Ayrshire the lines have been struck directly by lightning on several occasions, but beyond opening the automatic switches little difficulty has been caused It is important that children should be taught in schools the nature of conductors and insulators of electricity Possible dangers arising from high pressure conductors should also be pointed out In America there has been at least one fatality due to the wire of a kite flown by a boy nine years old coming into contact with a high pressure overhead wire A damp string in similar circumstances might conceivably be dangerous

IN a paper read to the North East Coast Institution of Engineers and Shipbuilders on Feb 7, Mr S Cook discussed the value of high pressure steam for marine work The significance of the term high pressure steam has changed with each succeeding generation of marine engineers At one time, even 15 lb or 20 lb per sq in was considered high pressure In early days, some of the foremost engineers declared against the use of high pressures, the theory not being understood Then, too, faulty construction often led to trouble To day, 200 lb per sq in may be regarded as a standard pressure at sea, though some ships are using steam at 300 lb or 400 lb per sq in pressure, while the Clyde steamer *King George V* has run successfully for three seasons with a boiler pressure of 550 lb per sq in and steam superheated to 750° F

INCREASES in thermal efficiency can be obtained by raising the pressure or temperature, and by means of tables Mr Cook set out the effect on thermal efficiency due to (1) superheat only, (2) increase of pressure only, and (3) increase of pressure and temperature From the tables it was shown "that an increase of temperature at 200 lb per sq in by superheating to 750° F increases the efficiency from 31 9 per cent for the saturated condition to 34 0 per cent for the higher initial temperature Whereas if this increase of temperature is accompanied by an increase of pressure to 1000 lb per sq in the efficiency is increased from 31 9 per cent to 39 8 per cent, a total improvement of 25 per cent, the greater part of which is due to increased pressure" In touching upon the type of boiler the quality of the feed water, the design of condensers, and other practical matters, Mr Cook made the interesting statement that, in spite of the high pressure in the *King George V*, in three and a half years it had not been found necessary to remake a single main steam pipe joint

THE issue of the *Journal of the Society of Chemical Industry* for Jan 24 contains an interesting illustrated article by Sir Robert Hadfield, T G Elliott, and R J Sargant on recent developments in corrosion and heat resisting steels They give a good historical account of the development of stainless chromium steel, in which the work in France from 1876 onwards, the discovery by Brearley in Sheffield in 1912 and after that this steel could be hardened, tempered, and polished for use in making stainless cutlery, and other investigations are reviewed Sir Robert then points out that his firm is now collaborating with the Fourchambault Co in France and the Midvale Steel Co of Nicetown, Pa, in the development of a series of heat-resisting steels These are of two types, those which are hardened by quenching and those which are softened In the former, chromium is practically

the only alloying element, and by varying the amount of carbon the steel may be made to range from a soft material suitable for stamping into dishes and pans to a hard steel suitable for knife blades The best corrosion resistance is obtained with somewhat higher chromium percentages, namely, 17 18, than the 12 5 14 formerly used A steel with 17 per cent or more of chromium and 7 per cent or more of nickel is not hardened by quenching and has superior corrosion resistance, although it is more expensive The article gives many details of the structures, resistance to acids, etc, of these steels, and also of their industrial applications, including furnaces and operations involving high temperatures and pressures

A PROPOSAL to excavate the Roman city of Verulamium was considered at a meeting of the St Albans City Council on Feb 4, when the Parks Committee presented a report which had been made by Dr R E Mortimer Wheeler on behalf of the Society of Antiquaries at the request of the Mayor The report stressed the importance of Verulamium, first as one of the great tribal capitals of prehistoric Britain, and secondly as one of the great centres of Roman Britain, which grew up as a city of the first rank a century or more before London was even founded It appears to be the only city in Roman Britain which attained the rank of a *municipium* Dr Wheeler suggests that the examination and consolidation of the better preserved stretches of the Roman defences should be given precedence These defences consist of a magnificent ditch, unequalled in Britain, a level platform or berm, behind this a wall of flint rubble with bonding courses of brick, and a broad and high bank piled against the inner side of the wall The wall is at present in some danger from the weather and the disintegrating action of ivy and tree roots When the defences have received attention, it is suggested that the plan of the town should be revealed and the principal buildings located The Council decided to appoint a committee for this work to which the Society of Antiquaries and the St Albans and Hertfordshire Archæological Society would be invited to appoint representative members

A PAPER was read on Jan 27 by Prof R A S Macalister and Prof J K Charlesworth before the Royal Irish Academy dealing with the archæological finds at Rosses Point, Sligo The announcement of the discovery of these implements was first made by Mr J E P Burchell in NATURE of Aug 20, 1927, p 260 An energetic discussion followed, during which directly opposing views were expressed, even by archæologists who accepted the human origin of the implements The geological evidence is almost unanimously opposed to the possibility of palæolithic implements being found in this particular part of Ireland Profs Macalister and Charlesworth expressed the opinion that until archæologists can reconcile their own differences, and find some means of squaring their conclusions with those of geologists, there is nothing to be gained for science from these implements

SIR DOUGLAS MAWSON'S Antarctic expedition has returned to Kerguelen to coal the *Discovery* It is now too late in the season to allow further exploration within the area of pack ice Reports to the *Times* summarise the season's work The edge of the land has been outlined between long 44° E and 66° E, including Enderby, Kemp, and MacRobertson Lands Farther east as far as 90° E the position of the continental margin has been indicated by soundings Much of the new coast line is fringed by ice cliffs The ice sheet is pierced by many rocky nunataks, and several definite mountain ranges have been charted, of which the principal is Scott Range in Enderby Land It has about 200 peaks, occasionally rising to 7000 feet, and some of these have been fixed From the rock collections on the coast, islets, and from the dredge there is every indication that this part of Antarctica is built of ancient crystalline and early sedimentary rocks Much oceanographical work has been done with the sonic sounder and deep sea water bottle This is probably more detailed than any previous expedition has been able to do High level meteorological observations show that at 5000 ft the principal air currents are from the north west to south east The strong gales off Enderby Land are from the east or north of east, and not from the south east as they are in Adelie Land and elsewhere on the plateau coast The pack ice is thus driven to the west or south of west, and the coasts of Enderby and Kemp Lands are kept comparatively clear except for the impediment offered by great rows of bergs, from farther east, stranded in the shallow water of the continental shelf East of Kemp Land there is much pack, reminiscent of the heavy ice of the Weddell Sea

A SHOWER of fishes from the sky might be reckoned one of the classic stories of anglers, were it not that abundant evidence exists of this natural phenomenon Dr E W Gudger, who on two previous occasions has recorded the results of his investigation of falling fish records, returns to the subject in the December *Scientific Monthly* In all, he has found about seventy one accounts, more or less well authenticated, of rains of fishes extending from A D 300 up to the present time, and in space encircling the whole globe He adds one or two new records in May 1900, at Rhode Island, when boys gathered and sold fishes by the pailful, and in May 1928, when hundreds of small fishes were deposited on a newly planted cotton plot at Tarboro, in North Carolina Of course, the explanation of the fish rain is the same in every case High winds, particularly whirlwinds, pick up water, fishes and all and carry them inland, and when the velocity of the air and clouds becomes relatively lowered, the fishes fall to earth

IN view of the serious aspect which the slaughter of whales for commercial purposes has assumed, it is significant that the economic extinction of whales falls to be recorded from a new area For the second time in history there are no longer sufficient whales along the Californian coast to support a whaling industry (*California Fish and Game*, p 337, Oct. 1929) In 1865 there were eleven whaling stations on the coast

of California, and a considerable fleet of ships was employed in the industry Writers often mentioned seeing fifteen whales at one time in one place, and in 1853 it was estimated that fully 30,000 Californian grey whales visited the California coast annually By 1880 the decline in whaling was noticeable, by 1890 practically no whaling was possible along the coast Then in 1919 with the gun harpoon and speedy ships with a hundred mile radius, commercial whaling again began in Monterey Bay In the new operations, as was to be expected, only four or five California grey whales were killed, but 781 hump backs were secured within three years Now the hump backs also have been reduced below the economic level In less than ten years of operation, the Moss Landing whaling station has been dismantled and operations abandoned because of lack of whales It is a fortunate thing that demand is not sufficient to endanger still more the surviving breeding stock No laws have been enacted in California to curtail the catch or otherwise to protect whales

In his Friday evening discourse on "Diving" delivered at the Royal Institution on Feb 7, Prof Leonard Hill showed and described the new sub marine escape dress which has recently been tested by the Admiralty He also showed a new self con tained diving dress with an injector for circulating the air in the helmet through soda lime and worked by the feed from a cylinder of oxygen and air With this dress the diver is independent of hose pipe and can detach and fix his life line containing telephone wires, and proceed with a distance line into a wreck The danger of oxygen poisoning has to be met by suitable concentration of oxygen in the air supply, and fixed periods of work at various depths The decompression of divers by the new submersible decom pression chamber of Mr R H Davis was dealt with and the use of oxygen for washing nitrogen out of the body, so halving the present times for decompression, was discussed Speaking of the danger of oxygen poisoning, Prof Hill suggested that air containing only 10 per cent or even 5 per cent of oxygen should be used for deep work at say 300 ft, the diver enriching the air he breathes with oxygen while climbing up, and then breathing pure oxygen on entering, at 66 ft, the submersible decompression chamber and while being decompressed in that chamber By such means diving at 300 ft or even 350 ft can be made safe

Mr Reijiro Wakatsuki, the chief Japanese dele gate to the Naval Conference, spoke to the people of Japan on Feb 9 by Marconi beam telephony from the Imperial and International Communications Marconi Beam station at Dorchester, his speech being relayed throughout Japan by means of the Japanese Broad casting Company's stations The wireless telephony apparatus designed by the Marconi Company was con nected to the beam telegraph aerial used for tele graphy with Japan, and reports received indicate that the transmission over the great distance separating the transmitting and receiving stations was very satis factory The incident is noteworthy because it was only six years ago that Marconi first transmitted in telligible speech to Australia, and the evolution of the system of combined telegraphy and telephony on the beam aerials marks the progress which has been made in transmission over long transcontinental distances

It is announced by the Hague correspondent of the *Times* that on Feb 10, M Reimer, Minister for Dykes and Waterways in Holland, opened the first pumping stations for the draining of the Wieringen Polder, the first of the polders to be completed in the scheme for the reclamation of the Zuider Zee One station is at Den Oever at the north, and the other at Medemblyk at the south of the polder, and about eight months will be required to free the polder of water The project for the enclosure of the Zuider Zee was described in an article in Nature of Sept 21, 1929, by Dr Brysson Cunningham The Wieringen or North west Polder, with an area of about 50,000 acres, is the smallest of the four polders contemplated When the whole of the reclamation work is completed, it is estimated that more than half a million acres, or about 10 per cent of its present area of arable land, will be added to Holland The enclosed area will not, of course, be immediately available, it is considered that six or seven years must elapse before it reaches its full cultivable value

Various agencies tend to an improvement of the condition of urban atmospheres None can be more welcome than the action of the Royal Institution of British Architects in issuing a report on smoke abatement (price 1s) The widespread damage to buildings has convinced the architects of the need, and they have much—sometimes all—of the responsibility for choosing the appliances for consuming fuel in domestic and other buildings There can be little doubt that if architects as a body strive to prevent the introduction of smoky appliances into buildings, considerable amelioration should in time follow The report gives an account of the law as to atmospheric pollution Technical information as to the effects of smoke and sulphurous impurities on buildings is given, and recommendation as to the choice of fuel and heating systems Little exception can be taken to the technical contents but here and there appear signs that no one on the Committee had first hand knowledge of fuels Still, the report is for architects, not fuel experts

The fourth annual report for 1929 of the Pharma cological Laboratories of the Pharmaceutical Society of Great Britain indicates that the time of the staff was divided between research work and the examina tion of samples submitted by manufacturers Some of the problems investigated were suggested by the revision of the "British Pharmacopœia" The director, Dr Burn, working with Prof Bijlsma and Dr Gaddum, has found that the oxytoxic value of a pituitary (posterior lobe) extract does not necessarily indicate its pressor or antidiuretic activity each property must be assayed separately The pressor principle has antidiuretic activity and also inhibits the fall of blood sugar produced by insulin Exam ination of samples of strophanthin by Mr Wokes

indicated that the average activity was only 60 ± 15 per cent of the international standard ouabain the strength of commercial tinctures of strophanthus was found by Dr Burn to be about equal to a 0 42 per cent solution of the standard ouabain, the majority lying between 0 31 and 0 53 per cent Dr Barba Gosè has investigated the toxicity of samples of tetraiodophenolphthalein, the determinations being carried out by intravenous injection into the tail vein of mice the criterion used was the death of half the animals within three days The toxicity was found to vary from 0 27 mgm to 0 37 mgm per gm mouse Dr Coward, who is in charge of the nutrition department, has carried out a number of investigations on different vitamins With Key and Morgan she has obtained evidence of a new growth factor for the rat, which is found in certain samples of casein, in fresh milk, lettuce, fresh and dried grass, beef, liver and wheat embryo, but is absent from dried yeast and butter Its presence is essential in the synthetic diets used for assay of vitamins A or B Dr Coward has also found that cod liver oil contains from 50 to 150 units of vitamin D per gm , butter 0 8 1 0 unit per gm , milk 0 2 unit per gm as a maximum, and irradiated milk from 0 1 to 2 0 units per gm The staff of the Laboratory, together with attached workers, published seventeen papers during the year

AMONG the contributions contained within Vol 11 of *Nauka Polska*, 1929 (*Science and Letters in Poland*, an annual publication edited by Prof S Michalski) mention may be made of Prof Paul Rybicki's communication on " Learning in Relation to Social Life , Some Borderline Problems of Sociology and the Theory of Learning " and that by Prof S Ciechanowski, which gives an account of the position and needs of medical science in Poland The former article contains a close study of the subject, such as might be expected from so thoughtful a scientific worker as Prof Rybicki, whilst the latter is especially significant since it was only last spring that an important medical congress was held in Warsaw The considered views which Prof Ciechanowski now publishes indicate the lines upon which he believes Polish medical science should advance In this volume, too, Dr M Loret announces the results he has obtained from some searches into ancient archives for information concerning the Polish scholars in Italy and at Rome during the sixteenth, seventeenth, and eighteenth centuries A survey of scientific thought abroad is also included in *Nauka Polska*, and it is interesting to note that lectures recently delivered by Prof R A Millikan (" Science and Society "), Sir James Ewing (" A Century of Inventions ", NATURE, **121**, 947 , 1928) and Prof J F Thorpe (" Co operation in Science and Industry ", NATURE, **123**, 531 , 1929) have been considered of such importance that they are now made available for Polish students Mention is made also of the formation of the Parliamentary Science Committee in Great Britain last year Finally, there is a lengthy survey of recent acts and regulations issued by Polish legislative bodies and higher education authorities and an account of the purely educational and scientific (especially biological) aspects of the exhibition held last year at Poznan

IN connexion with the anniversary of Galen's birth (A D 130) a small exhibition has been prepared at the Welcome Historical Medical Museum, 54 Wigmore Street, W 1

PROF G VON HEVESY, of Freiburg im Breisgau, will deliver the Hugo Muller Lecture of the Chemical Society on Wednesday, Mar 26 The title of the lecture will be " The Chemistry and Geochemistry of the Titanium Group "

DR W H MILLS, University lecturer in organic chemistry in the University of Cambridge, has been awarded the Longstaff Medal for 1930 of the Chemical Society for his distinguished researches in organic chemistry, especially in its relation to stereochemistry The presentation of the medal will be made at the annual general meeting on Mar 27

SURGEON CAPTAIN SHELDON FRANCIS DUDLEY has been awarded the Chadwick Gold Medal and Naval Prize of £100 for his medical and sanitary work and scientific researches during the past five years and before, directed to the prevention of disease among men of the Royal Navy The clause of the Chadwick Trust Scheme under which the award is made permits the presentation of a similar prize and medal once in every five years to a medical officer of the Navy, Army, or Air Force who, in the opinion of the Medical Director General of his arm of the service, shall have in the preceding five years specially assisted in promoting the health of the men of the force to which he is attached

THE Essex Field Club will celebrate its fiftieth anniversary on Saturday, Feb 22, when a special commemoration meeting will be held in the Great Hall of the West Ham Municipal College, at which a number of distinguished scientific workers and others interested in the Club will be present The president of the Club, Mr D J Scourfield, and the Mayor of West Ham will hold a joint reception at three o'clock in the afternoon, and speeches will be made by the Countess of Warwick, the Lord Lieutenant of Essex, the Chairman of the Essex County Council, Sir Henry Miers, Sir A Smith Woodward, and Sir David Prain An evening conversazione will follow, when a special exhibition of natural history and microscopical objects and of topographical photographs and prints of Essex will be made, and lantern lectures will be given by Mr W E Glegg and Mr S Hazzledine Warren The Club's Museum, which adjoins the College, will be closed to the general public, and will be available for inspection by guests on the occasion

WE have received Part 4 of Vol 3 of the *Peking Society of Natural History Bulletin* (June 1929, Peping The China Booksellers 1 50 dollars) It contains six scientific articles, of which no less than four are written by Chinese university graduates The subjects treated include the reproductive system of a Chinese Katydid, the anatomy of water snails, and the taxonomic characters of dragonflies and

Cyclops, all of which are illustrated by black and white plates The Society is to be congratulated on being able to issue this well printed journal, which is destined to become the medium for making known zoological discoveries in China

THE latest catalogue (No 340) of Messrs W Heffer and Sons, Ltd, Petty Cury, Cambridge, gives the titles of nearly 3000 volumes dealing with mathematics, physics, astronomy, chemistry, metallurgy, anthropology, ethnology botany, agriculture, geology, geography, medicine, physiology, zoology, and biology It also contains a lengthy list of portraits of men of science

APPLICATIONS are invited for the following appointments, on or before the dates mentioned — A senior lecturer in science at the Notts County Technical College and School of Art, Newark—The Principal, County Technical College and School of Art, Newark (Feb 17) A bacteriologist and pathologist under the County Borough of Belfast and Belfast Port Sanitary Authority—The Town Clerk, Belfast (Feb 21) A technical assistant under the Directorate of Ordnance Factories of the War Office—The Permanent Under Secretary of State for War (C 4), War Office, Whitehall, S W 1 (Feb 22) Temporary assistant chemists at the Government Laboratory—The Government Chemist, Clement's Inn Passage, W C 2 (Feb 22) A demonstrator in the Division of Bacteriology and Immunology of the London School of Hygiene and Tropical Medicine—The Secretary of the London School of Hygiene and Tropical Medicine, Keppel Street, W C 1 (Feb 24) A lecturer in physics at Chelsea Polytechnic—The Principal Chelsea Polytechnic, Manresa Road, S W 3 (Feb 25) A scientific assistant under the Board of Greenkeeping Research —The Director of Research, St Ives Research Station, Bingley, Yorks (Feb 28) Two junior technical officers in the Admiralty Technical Pool for an Admiralty Experimental Establishment, mainly for work in connexion with acoustical and electrical apparatus—The Secretary of the Admiralty (C E Branch), Whitehall, S W 1 (Feb 28) An assistant dairy bacteriologist in the Department of Agriculture and Horticulture of the University of Bristol—The Registrar, The University, Bristol (Mar 1) A scientific research officer in the Irrigation Branch of the Punjab Public Works Department—The Secretary to the High Commissioner for India General Department, 42 Grosvenor Gardens, S W 1 (Mar 31) A farm manager and lecturer in animal husbandry and a stockman and dairy instructor at the Arab Agricultural School, Tulkarem, Palestine—The Private Secretary (Appointments), Colonial Office 2 Richmond Terrace, Whitehall, S W 1 (Mar 31) A professor of physics at East London College—The Academic Registrar, University of London, South Kensington, S W 7 (April 8) A professor of geography at Birkbeck College—The Academic Registrar, University of London, South Kensington, S W 7 (April 10) A lecturer in petroleum production, in the Department of Oil Engineering and Refining of the University of Birmingham—The Secretary, The University, Birmingham (April 16) A reader in physics in the University of Dacca, East Bengal, India—The Registrar, the University of Dacca, East Bengal, India (April 30)

Our Astronomical Column

Prediction of the Sunspot Curve - Prof Dinsmore Alter gave an address at the meeting on Jan 1 of the British Astronomical Association, in which he described researches on the effects of the different planets on sunspot activity The method adopted was that described by Prof E Brown in vol 69 of *Mon Not Roy Ast Soc* Prof Brown noted that the sunspot period was not very different from the period of Jupiter, he found that by combining the tidal influences of Jupiter and Saturn he could get a curve that followed that of the observed sunspot activity very closely His prediction of a late maximum in 1907 was fulfilled, since then the curve has been carried on to 1955, and its agreement up to date with the observed curve is fairly close, though the 1917 maximum is predicted too early Later, the inner planets were introduced, since tidal action varies as the inverse cube, this partially compensates for their smaller masses, the fact of the tidal influence being appreciable is explained by the approximate equilibrium between gravitation and light pressure at the sun's surface

Observers' Handbook —This annual, issued by the Royal Astronomical Society of Canada, is edited by Prof C A Chant, and contains this year a useful catalogue of stars down to magnitude 3 5 It gives magnitude, both apparent and absolute, proper motion, parallax, distance in light years and radial velocity There is a similar list for stars within 5 parsecs of the sun the latter list has been steadily growing, and now contains 35 stars, of which only four exceed the sun in luminosity The one of smallest luminosity is Wolf 359, the absolute magnitude of which is 16 5, implying that its luminosity is one fifty thousandth part of the sun's In the list of satellites the name 'Triton' is inserted for Neptune's satellite This very suitable name was suggested by the late M Camille Flammarion, and is now adopted by many astronomers

The Constant of Aberration —The fact that aberration has an annual period introduces the difficulty of eliminating seasonal effects, due to temperature or other meteorological causes, from measures made for its determination Mr H R Morgan contributes a paper to *Astr Jour* No 933, in which he deduces a value for the aberration constant from observations in declination of stars near the pole made with the 9 inch transit circle at the U S Naval Observatory, Washington, between 1903 and 1925, as the stars were observed at both upper and lower culmination, the observations being made near the beginning and end of the night (at which times the aberration is almost wholly in declination), and each star was observed twice in the year at intervals of 6 months, reasons are given for believing that seasonal terms have been nearly eliminated This conclusion is supported by the fact that different groups of stars give accordant results The value adopted for the constant is $20\ 479'' \pm 0\ 008''$ Using Michelson's latest value for the velocity of light, the corresponding distance of the sun is 92,895,300 miles, and its parallax is $8\ 800'' \pm 0\ 003''$

Research Items.

Migration of Birds and Sex Cycles—By a series of experiments on the junco (*Junco hiemalis connectens*) Prof William Rowan has shown that the rhythm of the reproductive organs can be interrupted almost at will by appropriate lighting conditions (*Proc Boston Soc Nat Hist*, vol 39, No 5, 1929) He has thus succeeded in arresting the normal spring recrudescence of the gonads, in causing premature recrudescence in mid winter, and by alternate over and under lighting causing a maximum recrudescence three times and a minimum reduction twice in the course of a normal single cycle of a year Further, even in the absence of light, increasing periods of compulsory exercise cause a recrudescence of the gonads It is suggested, therefore, that the increase of light permits increased exercise and that this is the crucial factor in inducing the development of the gonads Birds which were released while the sex organs were in process of increasing or dwindling migrated, while those set free at the state of maximum or minimum development showed no inclination to move away Rowan shows that the spring recrudescence of the sex organs cannot be due to rising temperatures, or the autumnal retrogression to falling temperatures, as has been supposed While these conclusions apply primarily to the junco, he sees no reason to believe that it is exceptional

Breeding Habits of South African Frogs and Toads—Three papers in the *Annals of the Transvaal Museum* (vol 13, No 3, 1929) describe the breeding habits and the early development of several species of frogs and toads found in the neighbourhood of Stellenbosch The appearance of temporary puddles and full drainage furrows following the winter rains is the signal for spawning The distribution of the spawn shows a certain selectivity of pool conditions on the part of the spawners, and a case of mass spawning illustrated differential survival In a temporary pool two species of *Rana*, one of *Cacosternum* and one of *Bufo*, spawned one morning and the young hatched, but on the examination of the larvæ when the pool had eventually dwindled to a square foot in area, only examples of *Rana greyi* were found C G S de Villiers describes the food of the different tadpoles, their characteristics and development, and gives hints for keeping alive and preserving examples for subsequent examination He warns collectors against preserving amphibian larvæ in alcohol, which invariably results in shrinkage of the tissues and serious distortion Where field conditions make the narcotising of the larvæ and preservation in a fixative containing sublimate impossible, formalin or carbolic acid is recommended It would have been convenient had titles been attached to the figures and had a short summary followed the longest paper V Fitzsimons and G van Dam give for the first time an account of the breeding of *Breviceps*

Californian Salmon—In a paper on the Sacramento San Joaquin salmon (*Oncorhynchus tschawytscha*) fishery of California, Mr G H Clark (Division of Fish and Game of California, *Fish Bulletin* No 17) gives a review of the history of this fishery A serious decline set in after 1918, and in 1926 and 1927 the commercial catches were lower than they had been in any year since 1874 This is attributed to a depletion brought about chiefly by over fishing, for which ocean trolling is most responsible, and by dams obstructing streams and cutting off spawning grounds The author includes in his report a survey of the spawning grounds of the Sacramento and San Joaquin river systems and some information on the life history of the salmon It is noted that ocean trolling accounts for the taking of numbers of immature fish as well as mature, and the biological work aimed at ascertaining the age of maturity of the salmon and the percentage of age classes which mature in a given year It was found that 50 per cent of the fish mature at four years of age, the five year and three-year fish following in order of abundance It is thought that 70 90 per cent of the young salmon go to the sea during their first year

Pelagic Polychætes of the *Terra Nova* Expedition—The Report on "The Pelagic Polychæta" of the British Antarctic (*Terra Nova*) Expedition, 1910 (Natural History Report Zoology Vol 7, No 3, British Museum (Natural History), 1929), by Dr William B Benham, includes eleven species belonging to three families Of these the Alciopinæ are the most important, two new species, both from New Zealand only, being described These are *Vanadis augeneri* and *Callizona grayieri* The widely distributed *Alciopa cantrainii* and *Torrea candida* are now shown to occur in the waters round the northern coasts of New Zealand The Alciopinæ may be regarded as Phyllodocines which are modified for a pelagic life and are here placed in the sub family Alciopinæ belonging to the family Phyllodocidæ Of the four species of *Tomopteris*, most is said about the Antarctic *Tomopteris carpenteri* and there is a long discussion as to whether this species possesses a 'tail' Apparently it has none, and the tomopterid from South Africa recently described by M'Intosh as *T carpenteri*, which has a 'tail', seems to be a different species

Elm Disease—The so called Dutch elm disease is so insidious in its spread that any research which throws light on this subject is of great economic importance J G Betrem (*Meded Laborat Entomol Landbouwhoogeschool*, Wageningen, Holland) has published a paper in Dutch, with a German summary, in which he considers it proved that the disease is spread by the elm beetle (*Scolytus scolytus*) In a series of experiments he showed that when beetles are shaken up with distilled water and the water is plated out on nutrient agar, the fungus, *Graphium Ulmi*, now usually considered to be the cause of the disease, dominates the resultant growths Further, beetles allowed to run over sterile nutrient agar caused much infection by *Graphium Ulmi*, and finally, when the intestines of beetles were removed and inoculated into agar, they gave rise to the fungus almost exclusively

Afforestation in South Africa—South Africa is about the only Dominion of the Empire with but a small area of indigenous forest extant A great deal of attention has therefore been concentrated of late years on afforestation work, mainly with exotics Dr H M Steven's paper, entitled "Afforestation in South Africa", in the second issue of vol 3 of *Forestry*, makes it evident that a great deal of high class work has been undertaken and a considerable experience gained in all the branches which such operations entail Experience has to be bought by 'trial and error' and careful research Many problems remain to be answered, but the paper gives evidence that the forestry authorities are on the high road to solving certain questions as to the species which will offer the best hope of success whilst at the same time providing the Dominion with an increasing amount of the types of timber hitherto imported

Falcon Island a Pyroclastic Cone—The December, 1929, number of the *Amer Jour Sci* contains an

interesting study of Falcon Island, an active Tongan volcano, by J E Hoffmeister, H S Ladd, and H L Alling The island is described as a typical South Sea island in the making It is a pyroclastic cone built by explosive eruptions Not a single lava flow has been found on the island, but the pyroclasts, which are mainly of dark brown glass, contain labradorite and pyroxene and are clearly of basaltic type Many islands of the south west Pacific have been built up in this way from the Eocene onwards There is here no evidence that pyroclastic action marks the waning stages of vulcanism Eua, near Falcon, has a core of volcanic tuff which is over lain by Eocene limestone White Island, near New Zealand, is a modern representative Such conditions do not exist in the Hawaiian Islands of the north Pacific The present Falcon Island is considered to be an example of the first stage of island formation in the South Seas The second stage is the reduction of the mound of ash and scoria to a shoal or sub marine bank Upon this, organic deposits then accumulate and an atoll may ultimately be produced A fourth stage is recognised when uplift of the limestone capped bank takes place, Eua being an example Falcon Island lies on the well marked fault line which stretches from Samoa to New Zealand, a line on which many volcanoes, active or dormant, are situated

Chemical Denudation —In a report on *Den Kemiska Denudationen i Sverige* (with a summary in French), J V Eriksson presents the results obtained during the period 1909-25 by the Swedish Bureau of Hydro graphy and the National Service of Meteorology and Hydrography in the course of a detailed study of the transport by Swedish rivers of materials in suspension and solution (*Medd f Statens Meteorologisk Hydro grafiska Anstalt*, Bd 5, No 3, pp, 96, Stockholm 1929) Work was carried out at 69 stations and 11,313 analyses were made The final results are given in metric tons of material removed per year from each sq km of the areas investigated, the latter covering 57 per cent of the whole country It is noted that it would be unsafe to assume that the total for the whole country could be obtained from the ratio 57 100, since the terrains not yet studied are mainly coastal or argillaceous In a series of excellent maps, the geographical distribution of the re sults is presented graphically for inorganic materials organic materials, CaO, Cl, and SO_3 Annual and seasonal variations are well brought out by tables of comparative figures In dominantly calcareous regions chemical denudation removes 60 to 70 tons/km ^{2}/year, whereas in forested areas the figure is generally about 10 tons Comparison with results for other countries (Europe, North America, and the Nile) shows that in recently glaciated lands chemical de nudation makes up 80 to 90 per cent of the total, whereas corresponding percentages are for the Mississippi 13 to 46, for the Rhone 19 to 66, with an average of 23, for the Blue Nile 17, and the White Nile 72 It is concluded that in Sweden chemical denudation amounts to 70 to 90 per cent of the total

Isotopes of Nitrogen —The recent discovery of oxygen isotopes of atomic masses 17 and 18, and of a carbon isotope of mass 13 (see NATURE, Mar 2 and June 1, 1929, vol 123, pp 318 and 831, and Aug 3, 1929, vol 124, p 182) has now been followed up by the announcement by S M Naudé in the first number of the *Physical Review* for December of the discovery of an isotope of nitrogen of mass 15 If this existed, it should produce some additional band heads near 2156 A in the spectrum of nitric oxide, and a search for these indicated that they were actually present, very close to the predicted positions The bands were examined in absorption, and the possibility that the reputed isotope effect was due to the presence of molecules such as $(NO)_2$ ruled out by the fact that the relative intensity of the various band heads was independent of the pressure of the nitric oxide Nitric oxide $N^{15}O^{16}$ is about as abundant as nitric oxide $N^{14}O^{18}$ Some very faint absorption lines have also been observed which agree with those calculated for the molecule $N^{16}O^{16}$, but the existence of this third isotope, of atomic mass 16, must still be regarded as uncertain

An Ammeter for High Frequency Currents —The problem of measuring alternating currents of very high frequency has come rapidly to the front during recent years owing to the extensive use of radio communica tion In the early days of electric supply, power engin eers sometimes thought that possibly there were large losses in their mains owing to the so called 'skin effect' This effect caused an uneven flow of current across the section of the main, the current density as a rule being greatest near the surface One of the advantages of concentric mains in the old days was supposed to be that they largely diminished this loss It is only, how even, when the mains are very large that this loss be comes notable at the standard power frequency of 50 When frequencies of 100 million are used as in radio work, the skin effect becomes enormous, and many attempts have been made to obviate the difficulties it causes At this high frequency an ordinary ammeter would, owing to its inductance allow practically no current to flow in the circuit In a paper read to the Institution of Electrical Engineers on Feb 5, Prof C L Fortescue described an ammeter he has invented which practically overcomes all the difficulties hitherto experienced He points out that these difficulties arise from three main causes That the capacity effects make the current in the instrument different from the current outside, secondly, even very short conductors have a high inductive reactance at high frequencies, and thirdly, the presence of the measuring device in the circuit changes the value of the current that has to be measured He gets over the difficulty by using a thin wire screened by and coaxial with a concentric cylinder The instrument is calibrated with direct current, and he shows how the true current can easily be calculated by theory

Laboratory Hot-Water Ovens —We have received from Messrs Brown and Sons, Ltd, 9 Wedmore Street, Holloway, N 19, an illustrated booklet which contains particulars of the patent 'Sanbro' laboratory hot water ovens By means of a very simple device the boiler at the base of the oven can be removed, cleaned, and replaced within a few minutes and without the use of special tools Moreover, when the deposit in the boiler becomes excessive, the latter can be replaced by a new one at a small cost The boiler consists of a loose pan to the inside of the top rim of which is fixed a gutter into which the oven proper fits The two parts when fitted together form the steam chamber, an air tight connexion being pro duced merely by a layer of water which forms an effective seal The ovens, which have already been installed in many laboratories with satisfactory results, can also be combined with water stills The great advantage of this new device will be at once apparent to anyone who has had to incur the cost of repairs to oven stills of the older type, in which hard water has been continuously used The device can be fitted without much trouble to existing ovens of the sealed up type and can be adapted to various kinds of heating supply

Chemical Warfare

DR HERBERT LEVINSTEIN, in a lecture delivered on Feb 3 before the London section of the Society of Chemical Industry, courageously examined the position of chemical disarmament and chemical warfare in relation to the ideals and foundations of future peace and to the stern realities of the dangers of conflict Whilst it is probably true that man is by nature a peaceable creature, and hence amenable to the settlement of domestic disputes peaceably under compulsion of law, the extension of the same principle to international disputes, however devoutly to be sought, is not so simple as may appear The necessities of life are provided for the individual who falls in the social struggle but not for the nation which succumbs in society organised on competitive principles, and the possibility of defensive resort to arms remains in the background of international agreements Hence with the present organisation of society the possibility of fighting is never remote, and Dr Levinstein's first plea was for the strengthening of the efforts of the League of Nations in making wars on a large scale less probable

In international disputes, arms are the last resort, other means of persuasion are equally available, and not the least powerful is the possession of a powerful chemical industry Restriction of naval armaments, largely an economic measure, by making war cheaper tends in a sense to make it easier, and in Dr Levinstein's opinion increases the importance of the chemical arm Examination of the text of the agreements relating to the prohibition of chemical warfare leads to the conclusion that the prohibition is largely ineffective He finds, for example, no prohibition of the use of screening smokes, yet it may be argued that such smokes as that of chlorosulphonic acid are in concentrated form deleterious to the human organism and are therefore forbidden Justification of the use of a smoke can be based on the grounds that its toxic properties are accidental, as indeed are those of the fumes from high explosive shells Tear gases, used in the United States for the protection of banks and safe deposits and for dealing with riots and civil disturbances, may be classed as non asphyxiating and non poisonous, since in low concentration they affect the eyes alone

Chemical warfare has not, said Dr Levinstein, been justly condemned by the general opinion of the world, condemnation lies against its use by the Germans in 1915 in violation of the spirit, if not of the letter, of the Hague Convention, and because it was used against unprotected troops He asked why preference should be shown for the use of high explosives with their ghastly effects, there is, unfortunately, no prohibition against the dropping of high explosive shells or incendiary bombs from hostile aircraft at dead of night on crowded cities

The object of war is not to destroy human life, but to break down the opponent's will to resist Gas, Dr Levinstein claimed, maims or kills a far smaller proportion of those whom it puts out of action than does any other weapon used in the recent War, thus in proportion to the military results it causes far less human suffering, and, in addition, less of the wasteful destruction of the work of man Dr Levinstein quoted statistics showing that of the casualties caused by gas only 2 3 per cent died and few—about 0 5 per cent—were permanently injured, whilst of casualties resulting from all other forms of warfare 25 33 per cent died, and of the survivors 2 5 per cent were maimed, blinded, or disfigured for life He did not suggest that gas warfare is anything but dreadful, but he argued that it is both less dreadful and of greater military value than the older forms of warfare It causes inconvenience, holds the element of surprise, permits economy of force, and is equally serviceable in attack and defence

In Dr Levinstein's opinion it is an elementary act of prudence for a nation situated as is Britain to see that research for chemical warfare purposes should continue to be a subject for special study, and that funds for that purpose should not be reduced below the safety point Guns and shells can be restricted, and in any case take long to prepare, but gas can be projected from quickly improvised containers, limitation of armaments as proposed may therefore greatly increase the military importance of the chemical weapon, and prudence dictates contact in peace time between military authorities and the chemical industries

If a purely general observation supplementing Dr Levinstein's remarks may be offered, it is simply that modern warfare in all its forms is increasingly based on chemical knowledge, and that if chemical research can make warfare even a little less probable and less hideous, its potentialities in that direction deserve the attentive interest and unbiassed support of all right minded men and women

Variations in the Skeletal Structure of the Pig

HAVING observed marked variations in the lengths of exhibition carcases of swine used for bacon curing, Prof A M Shaw, of the University of Saskatchewan, suspected that the difference might be due to variations in the numbers of ribs He accordingly counted them and found that, of nine carcases exhibited, two possessed 16 pairs of fully developed ribs, four possessed 15 pairs, while the remaining three carcases possessed 14 pairs of fully developed ribs each

Reference to standard works on veterinary anatomy was made Sisson states "The ribs number fourteen or fifteen pairs The fifteenth rib when present may be fully developed and its cartilage enter into the formation of the costal arch, but in most cases it is only about an inch (2 3 cm) in length" The vertebral formula given by Sisson is *C* 7, *T* 14 15, *L* 6 7, *S* 4, *Cy* 20 23 He also states that "the occurrence of fifteen thoracic vertebræ is quite common and the existence of sixteen or even seventeen has been recorded Reduction to thirteen is very rare" Various model pig skeletons examined by Shaw all possessed what was apparently considered to be the normal number, namely, 14 pairs

Prof Shaw has had careful counts made in Canada, the United States, Great Britain, and Denmark, and has now published the figures for 3957 animals, representing several breeds, grades, and crosses (*Scient Agric*, **10**, 1, September 1929) When summarised they show the following results 13 pairs of ribs, 20 pigs, 14 pairs, 1574 pigs, 15 pairs, 1829 pigs, 16 pairs, 310 pigs, 17 pairs, 7 pigs The remainder showed uneven pairs or floaters More than 400 vertebral columns were scraped and cleaned for identification, varying in number of ribs from 13 to 17 The counts showed that cervical (7) and sacral (4) remained constant, thoracic varied according to the number of ribs, while the lumbar variation is from 6 to 7, except in two cases, where there were only 5 present The true ribs were always attached to

thoracic vertebræ and the increase in lumbar vertebræ were associated with the smaller number of ribs present and vice versa There appeared to be no relationship between sex and the number of ribs Very interesting observations were made in regard to litter mates in that "no normal litters were found where all pigs possessed the same rib number"

In addition to the scientific value of these observations, the economic aspect of rib variation in pigs is of considerable importance from the point of view of bacon, since the increased length of the carcase is mainly in that region usually regarded as furnishing the prime cuts The awards in various competitions supports this, even though the judges apparently had no thought of rib count Moreover, in a private communication Prof Shaw states "there seems to be ample evidence that the animals with fifteen and sixteen pairs of ribs are decidedly superior from the standpoint of rate of growth and economy of gains to those possessing thirteen or fourteen pairs"

The Sugar Industry

THE world's sugar industry was the subject of the Streatfeild Memorial Lecture delivered at the Institute of Chemistry by Mr Lewis Eynon, on Nov 22, 1929, and recently published Sugar cane, which until about 130 years ago, was the only source of sugar, was known before the Christian era, and is supposed to have originated in India Arabs and Egyptians, however, were the pioneers in the art of crystallising sugar many centuries later Sugar appears to have been first imported into England from the Mediterranean countries in the fourteenth century, and the art of refining introduced during the reign of Henry VIII During the seventeenth and eighteenth centuries, however, the bulk of the world's sugar was derived from America and the West Indies, where abundant slave labour and good growing conditions particularly favoured the industry

Attempts to produce sugar from sources other than cane were first made in Europe during the Napoleonic Wars, when the possibilities of utilising grapes and beetroot were investigated, but without much success in the former case With the exception of France, where the industry obtained government support, it was short lived and did not become general in Europe until 1860

Despite the development of the beet sugar industry, the importation of cane sugar into Europe continued to increase for some time, and although during the latter part of the nineteenth century the cane sugar industry suffered temporarily from severe competition, the markets gradually adjusted themselves, and in 1901–2 cane and beet each contributed about 50 per cent of the world's production of sugar Sugar beet growing was first attempted in England seventy years ago, but the industry developed but little until the raising of the subsidy in 1925

Besides the cane and beet sugar industries, the production of glucose from starch, first discovered in 1811, is an important manufacture Improved methods, the discovery of new sources of sugar, and the extension of the industry into temperate climates have enormously increased the world's supply of sugar

Although sugar, at one time a luxury, has now become an important article of food, human consumption is not likely to increase at the same rate as the supply, and it seems that a new use for sugar must be found, or further growth of the industry will be impossible The production of power alcohol from sugar seems to be the solution of the problem, and it would also provide a useful substitute for petrol before the world's store of this is exhausted The future prosperity of the sugar industry would thus seem assured

Bacterial Infection in Fish

IN the issue of NATURE dated Dec 29, 1928 (p 1012), there appeared a short notice of recent work on furunculosis in Salmonidæ by Dr Clayton and Miss I J Williamson working independently Since then, Miss Williamson has continued and extended her studies on this disease, the results of which are embodied in two papers recently published by the Fishery Board for Scotland The external signs and visceral changes in furunculosis she finds to be variable, and there may be no external symptoms, isolation of the bacillus (*B salmonicidus*) often being the only method of diagnosis [1] A notable and very important feature of the disease is that apparently healthy fish can act as 'carriers' of the bacillus, but no means has as yet been evolved for distinguishing such 'carriers' from uninfected fish while still alive Rainbow trout can also be attacked by the disease, and act as 'carriers' of it It is interesting further to note that, up to the present, no case of furunculosis has been found among salmon smolts or among kelts, nor have any such fish been found to be 'carriers', but too few fish have as yet been examined to attach any but provisional value to this statement

In the course of her investigations into furunculosis of Salmonidæ, the author has made additional general observations on bacterial infection in fish and certain other lower vertebrates [2] It is found that organisms, naturally saprophytic may under certain conditions become pathogenic Those organisms comprise types frequently found in water, such as *B fluorescens* and certain Gram negative, non sporing, non chromogenic bacilli

Bacterial disease of fish and frogs usually takes the form of a general infection Focal lesions may or may not be found In furunculosis, infection may be both focal and general Secondary infections, including ante mortem infection, are of common occurrence in fish and frogs when the resistance of the animals has been lowered by primary infection, injury, and (possibly) other adverse conditions Little or no tissue reaction against invading bacteria analogous to such reactions in mammalian animals has been found in frogs or fish, but a certain degree of phagocytic activity is displayed in some cases "It seems certain", says the author, "that many water organisms are potentially pathogenic for fish, so that when they are injured or their resistance lowered by adverse conditions, these organisms invade their tissues and usually produce a general infection Once bacteria have gained an entrance, they meet with but little opposition from the tissues and rapidly overrun the body"

[2] Fishery Board for Scotland Salmon Fisheries, 1929 No 2 A Study of Bacterial Infection in Fish and certain other Lower Vertebrates (with a Systematic Account of the Bacteria isolated from Fish and Frogs in the course of Investigation of Furunculosis of the Salmonidæ) By Isobel J F Williamson Pp 28 (Edinburgh and London H M Stationery Office, 1929) 1*s* 9*d* net

Historic Natural Events

Feb 16–19, 1898 Dust Haze —A dense haze occurred over a large part of the eastern Atlantic off West Africa, extending for at least 1500 miles north and south and a great but unknown distance east and west The haze was caused by very fine red dust, so fine that it was impossible to sweep it up, and so dense that the sun and stars were completely obscured for two days When visible the sun was generally red, but one observer described it as "a perfect blue ball" and another as greenish At Teneriffe the occurrence was preceded by a strong and very hot southerly wind, but during the haze there was no wind Many insects were observed, of species not generally found on the island The dust evidently originated in Africa, for it was much coarser near the coast, and was thrown overboard from ships in large quantities

Feb 18, 1770 Damage by Lightning —During morning service St Keverne's Parish Church, Cornwall, was struck by lightning The vicarage seat was torn to pieces and a large piece of oak was thrown 20 feet The vicar's sister was knocked down senseless, the wooden part of one of her pattens was broken and it and her shoe were burnt, as well as parts of her clothes and body The spire was rent, and stones from it were thrown on the tops of many houses, one that fell through a roof was found to weigh 14 lb Some smaller stones were found at a distance of a quarter of a mile

Feb 20, 1661 The 'Dantzig Phenomenon' —A remarkable and extremely beautiful halo complex was seen at Dantzig between 10 30 and 11 51 A M In addition to the usual halos of 22° and 46°, the circumzenithal ring and various arcs of contact, there were no fewer than seven mock suns, some white, some of various colours, arranged with perfect symmetry This is probably the most complete optical display on record

Feb 20, 1835 Great Earthquake —Concepcion, Talcahuano, and other Chilean towns were ruined by an earthquake felt over an area of more than 400,000 square miles Sea waves, 28 feet and more in height, swept over the coast and even caused damage at Juan Fernandez, 420 miles from Chile The coast of Chile was raised by 4 or 5 feet, though it afterwards subsided by half that amount The volcanoes of the Chilean Andes, a range 150 miles in length, were unusually active before, during, and after the earthquake

Feb 21, 1861 Great Storm in Southern England —This storm was noteworthy for the destruction of a wing of the Crystal Palace and of the cathedral tower at Chichester, which fell in spite of desperate efforts to shore it up

Feb 21, 1922 Glazed Frost —During the night of Feb 21, in the region of the Great Lakes, a light rain fell at a temperature below freezing point A coating of ice formed on everything out of doors, and as the rain continued falling, the ice grew thicker Trees were so heavily coated that they began to give way and the air was full of rifle like reports as the huge limbs snapped off Sidewalks in streets were piled high, and as the rain continued whole streets became blocked as the trees were split from top to base and fell Trains ceased to run, and telegraph and telephone wires were snapped by the weight of ice Newspaper presses stopped, and only the radio enabled people to keep in touch as they could not venture into the streets Recovery was slow The train service resumed after several days, but it was months before all the telegraph equipment was replaced

Feb 21–23, 1903 Red Rain —Dust or 'red rain' fell over an area of 20,000 square miles in the southern half of England and Wales as well as in many countries on the Continent It is estimated that in England and Wales alone the total quantity of dust was not less than 10 million tons It was traced back to the Sahara, south of Morocco, where it was raised by a strong north east wind, it travelled on the western side of an anticyclone over south west Europe for a distance of at least 2000 miles in a wide sweep around Spain and Portugal, probably across the Azores In Europe the fall was associated with oppressive heat, and visibility was limited to short distances

Feb 22, 1909 Meteor Trail —A very fine meteor passed the length of the English Channel at 7 34 P M from a point 45 miles south south west of Beachy Head to 87 miles south south east of Start Point This distance of 150 miles was traversed in less than six seconds, giving a velocity of at least 25 miles per second relative to the earth at a height of about 50 miles The meteor left an unusually well developed 'streak', which was visible for nearly two hours It brightened appreciably in the first half minute, and the main part drifted gradually north westward while the ends remained almost stationary The long continued brightness of the streak was attributed to some unknown form of electrical action, possibly similar to the aurora, rather than to incandescent matter

Societies and Academies

LONDON

Royal Society, Feb 6 —**A H Davis** and **E J Evans** Measurement of absorbing power of materials by the stationary wave method The paper describes an apparatus set up for determining the acoustical absorption coefficient of small samples of material for sound, incident perpendicularly, and discusses the theory of the method and of its corrections Stationary wave coefficients for certain practical materials are compared with coefficients obtained by a 'reverberation' method, in which random incidence of sound is employed —**J W Fisher** and **H T Flint** The equations of the quantum theory These equations are obtained by analogy with Maxwell's equations applied to empty space They are expressed by means of a five dimensional system of co ordinates with the adoption of a metric after the manner of Weyl and Eddington in four dimensions The quantum problem is shown to be a radiation problem in five dimensions, and the equations proposed are invariant —**J Hargreaves** The effect of nuclear spin on the optical spectra (2) The paper contains a general method for dealing with the effect of a nuclear spin of possibly more than half a quantum, by the use of multiple wave functions, and is applied in detail to the cases of a nuclear spin of 1, 1½, and 4½ quanta respectively The interaction energy of the nucleus and electron spins is neglected, without effect on the kinematical problem of determining the multiplet intensities — **E Rudberg** Characteristic energy losses of electrons scattered from incandescent solids The velocity distribution of an initially homogeneous beam of electrons, after scattering from a solid target kept at incandescence, has been studied by means of a magnetic deflection apparatus The curves show a sharp peak due to reflected electrons and several small maxima for slightly lower values of the energy These maxima are characteristic of the substance forming the target, their positions with respect to the reflected peak remain constant for a wide range of bombarding voltages, and when target and electron gun are rotated, are also independent of angle of scattering These maxima are associated with

inelastic collisions with the target atoms, involving definite energy changes, such as excitation and ionisation.—J. A. Gaunt: Continuous absorption. This paper investigates afresh the problem of the rate of absorption of light by electrons which are initially bound to a nucleus, or free and 'colliding' with a nucleus, and after absorption are free in either case. Such a process gives rise to a continuous absorption spectrum and is the main source of the general opacity in stellar atmospheres and interiors. The interest and difficulty of the problem lie in the effective evaluation of the formal quantum theoretical expression for the absorption coefficient. Kramers' classical formula is asymptotically correct in the region in which one would expect it to be so by the correspondence principle. The deviations of astrophysical significance are found. The discrepancy between the requirements of Eddington's stellar theory and Kramers' formula is probably retained by the quantum theory of continuous absorption.

Optical Society, Jan. 16.—**O. G. Hay**: The Ross modification of the Hilger interferometer is for testing large optical elements when the free aperture of the test element is larger than the normal aperture of the interferometer. A pair of mirrors moved over the surface to be tested reflect a test beam and a reference beam and so enable any two areas to be compared. Any error introduced, by mechanical motion, into the test beam is compensated by a similar error in the reference beam. The two beams are linked together throughout the whole of the optical train of the interferometer.—**J. S. Preston**: The reflection factor of magnesium oxide. The factors were measured by means of a small integrating hollow sphere with three openings, one for illumination, another for observation through a photometer, and the third covered by a test plate or by the specimen to be examined. Results: Total factor under diffused light = 0·0974.

EDINBURGH

Royal Society, Feb. 3.—**R. W. Wrigley**: On changes of rock temperatures and irregularities of the earth's rotation. The investigation is based upon a series of deep rock temperatures dating from 1837 taken at the Calton Hill. After the removal of the effects of atmospheric changes at the surface, the residuals show a certain fluctuation. A fifty years' series of deep soil temperatures at Greenwich, when similarly treated for the removal of surface variations, shows similar fluctuations. There is a close correlation between these temperature variations and the minor fluctuations in the moon's longitude. Sliding of the earth's crust over the core combined with more local variations of longitude may cause the latter, and the rock temperatures would be influenced by the consequent changes of pressure in intermediate layers of the earth's crust.—**S. Williams**: The morphology of *Trichomanes aphlebioides* Christ, with special reference to the Aphlebioid leaves. *T. aphlebioides* is endemic to New Guinea where it grows on tree trunks in humid forests. It was first collected by K. Lauterbach in 1890 and briefly described by Christ in 1901. The scandent rhizome possesses a protostele similar to that of *T. scandens*. The fronds measure up to 60 cm. long and are 4-5 pinnate. In addition to these normal fronds, the plant possesses hair-like aphlebioid leaves. These latter are borne singly at the nodes, and their position and structure indicate that they are the first fronds of the axillary branches. Anatomically they show great reduction in relation to the moist and shady habitat. They may serve to promote transpiration and possibly also to protect the young fronds.—**J. S. Patel**: The presence of a kuogenic substance in the corpus luteum of the cow. The corpus luteum of the cow contains not only a hormone which produces the pregnancy changes in the genital tract (corpus luteum hormone, beta factor), but also a water soluble substance which induces beta production in the ovary of the immature mouse. This substance was mistaken by many authors for corpus luteum hormone. It resembles certain pituitary extracts in action and chemical behaviour and is perhaps identical with the supposed RHO 2.—**P. Koller**: Genetic studies on the *A* and *B* races of *D. obscura*. The taxonomist cannot distinguish *A* from *B*, but cytologically and genetically they are dissimilar. The racial hybrid male is infertile, the female fertile. Experiment involving the use of several sex-limited characters and crossing over showed that the only male which was fertile was one with a *Y* chromosome of race *B* and a racially compound *X*, the ends of which were from *B*, the middle from *A*. Crossing over in the ends of the *X* was greatly reduced in the case of the racial hybrid. There are probably genes in the ends of the *X*, physiologically dissimilar in the two races, which determine fertility. The relation of puberty to testis size and to cytoplasmic constitution is examined. No such relation exists.—**F. A. E. Crew** and **L. Mirskaia**: Maturity in the female mouse. Puberty and maturity are distinguished and defined. In this study the albinos reached puberty earlier than did the coloured; in them the cornified stage of first œstrus lasted longer before mating, and more commonly they mated at the time of the first œstrus. Pregnancy following the first œstrus was more frequent.—**Alan Mozley**: Reports of the Jasper Park Lakes Investigations, 1925–26. The mollusca of Jasper Park. The Biological Board of Canada sent two expeditions under the charge of Dr. Chas. H. O'Donoghue to Jasper National Park in the Canadian Rockies to investigate the possibilities of augmenting its fishing facilities. The present report deals with the Mollusca mainly from the systematic point of view. Forty-seven species or varieties are recorded and described, and while none of them are new they nearly all vary from the previously known forms. The collection is noteworthy in two respects: first, all the specimens were taken at altitudes between 4000 ft. and 7000 ft.; and secondly, no such detailed study of fresh water mollusca has been made within a radius of 2000 miles. This report is intended to be preliminary to one dealing with the ecology of the group.

PARIS

Academy of Sciences, Jan. 6.—**Gabriel Bertrand** and **M. Mokragnatz**: The distribution of nickel and cobalt in plants. Nickel and cobalt have been found in all the plants examined. The quantities of nickel found, expressed on the dry material, range from 0·02 parts per million in polished rice to 3·5 parts per million in an edible fungus, *Cantharellus cibarius*. The proportions of cobalt are usually from one-fifth to one-tenth of the nickel present.—**Paul Pascal**: Amides and imides derived from vanadium. A study of the interaction of ammonia and vanadyl chloride at different temperatures. At −80° C. vanadyl amide, $VO(NH_2)_2$ is produced, but cannot be separated from ammonium chloride; at 85° C. or higher temperatures the imide VONH is formed.—**V. Lalan**: The fundamental tensors of plane varieties.—**Jacques**: Certain networks traced on quadrics.—**Maurice Janet**: A series of functions considered by Hermite and its application to a problem of the calculus of variations.—**R. Tambs Lyche**: A problem of interpolation.—

Vladimir Bernstein The regions of holomorphy of the series of Dirichlet —**Giulio Krall** The variation of domain in the problem of Dirichlet —**Fr Girault** The law of gravitation —**Maurice Nuyens** A new method of integration of gravific equations of a massic and electromagnetic field with spherical symmetry —**J F Cellerier** The scientific analysis of musical sounds The principle of the method employed is based on the conversion of the acoustic phenomena into electrical vibrations the characteristics of which can be determined with a high degree of precision As an example, the results of the examination of the note emitted by a motor horn is given —**J B Galle** and **G Talon** Researches relating to the propagation of radioelectric waves carried out on the occasion of the eclipse of May 9, 1929 In recognition of the importance of researches on the propagation of radio electric waves in its relations with solar activity, arrangements were made, on the occasion of the solar eclipse expedition to Indo China, to carry out measurements of the electric field produced by distant wireless stations, observations on atmospherics, and the apparent variations of emitting station as given by radio goniometry A summary of the results obtained is given —**G Ferrié** Remarks on the preceding note Comments on the results obtained in connexion with retarded wireless echos —**J Perreu** The limiting heat of solution of hydrated manganese chloride —**R Levaillant** Some reactions of sulphurous and carbonic esters Description of the preparation and properties of the compounds $SO_2[CH(CH_2Cl)_2]$, $(CH_2Cl)_2$ CH SO_2Cl, and $(CH_2 \; CH_2Cl)_2SO_4$ —**M Tiffeneau, Mlle Jeanne Lévy, and E Ditz** Some pairs of amino alcohols The preparation of each isomer separately In the preparation of the amino alcohols $ArAr'C(OH)CH(NH_2)CH_3$ by the interaction of the organo magnesium compounds with amino ketones, either of the two stereoisomeric forms predicted by theory can be obtained at will by inverting the order of introduction of the radicles Ar and Ar′ —**Raymond Delaby** and **Raymond Charonnat** The synthesis of dioxypyramidon —**Pierre Viennot** Intrusions of the Trias in the Adour basin —**Marcel Casteras** The structure of the mountains of Gar and Cagire (Haute Garonne) —**Louis Dangeard** Algal reefs and pebbles in the ferruginous oolite of Normandy —**Mlle A Dusseau** The chlorophyll of the leaves of wheat Physical measurements of alcoholic extracts of chlorophyll may serve for the identification of the variety of wheat —**Alphonse Labbé** The pallial organs of some Dorididæ —**A Policard** and **M Boucharlat** Contribution to the study of pulmonary anthracosis The tolerance of cultures of tissues towards particles of coal Results of growing lung tissue from the embryo fowl in plasma containing fine particles of coal in suspension No poisonous action of the coal could be detected These experiments tend to confirm the view that pulmonary anthracosis is an anatomical state and not a disease —**C N Dawydoff** The larvæ of the Polyclades of the coasts of Annam —**Emile F Terroine** and **Fr Szucs** The relation between amino puric nitrogen and proteid nitrogen in micro organisms —**H Hermann, F Caujolle, and F Jourdan** The elimination of some alkaloids and some genalkaloids by the bile ducts The presence in the bile of quinine, nicotine, strychnine, and genostrychnine, atropine, and genatropine has been proved —**R Fosse, A Brunel, and P de Graeve** A new fermentation of uric acid produced by the liver of various animals Uric acid can be totally converted into allantoin by a ferment in horse liver or by the liver of *Rana viridis* —**Mlles Marguerite Champagne** and **Gilberte Mourot** The estimation of allantoin in animal urine —**J Magrou** The interpretations of biological actions at a distance —**H Bordier** The efficacy of medical d'Arsonvalisation in erythematous lupus

GENEVA

Society of Physics and Natural History, Nov 21 —**G Tiercy** The new refrigerating installation of the chronometric department of the Observatory of Geneva The Observatory of Geneva has recently completely reorganised its chronometer service In particular, an apparatus has been set up for testing chronometers with a modern automatic refrigerator, this installation can keep a temperature in the chronometer chamber which is constant within 0 2° C The same constancy can be maintained in the chambers used for higher temperatures —**R Wavre** A possible agreement between geodesy and the theory of the precession of the equinoxes D'Alembert put the following problem Are the geodesic measurements of the terrestrial flattening entirely included between the limits which are assigned to them by the theory of precession? Poincaré showed that the studies, to the first approximation, of Clairaut and his successors led to a disagreement He did not determine the agreement possible using the second approximation The author, who has made a methodical study of the second approximation, shows that this agreement is possible The problem of D'Alembert may be solved without abandoning the fluid character of the earth considered as a whole —**E Briner** and **H Kuhn** Some new ammonia addition compounds of phenols On the basis of a manometric method, the authors have detected and characterised by their formulæ, dissociation pressures and heats of formation, numerous new compounds formed by ammonia with phenols, naphthols, oxy anthraquinones, and substituted derivatives of these substances —**B Susz** and **E Briner** The true energy yields in the production of ozone by the silent discharge and their improvement The authors have established by electrical and calorimetric methods the true yields in the production of ozone by the silent discharge These yields, improved by cooling, exceed 200 grams of ozone per kilowatt hour This makes the use of ozone particularly economical

LENINGRAD

Academy of Sciences (*Comptes rendus*, No 20, 1929) —**P Lazarev** and **L Teile** The action of blood vessel dilators on the sensitiveness of the eye in peripheral vision Experiments were made with amyl nitrite and nitroglycerine and it was found that these substances cause after the first 1 3 minutes a sharp decrease in the sensitiveness of the eye, then an increase occurs and after 5 9 minutes the sensitiveness becomes more than double the normal minimum —**P Lazarev** and **N I Kolesnikova** The staining of boric glass by the action of radium rays No effect has been observed from the action of γ rays, β and γ rays acting together produce a purplish brown stain, the combined action of α and β rays results in producing a substance with a high absorption in the blue part of the spectrum and smaller absorption in the red part The substances produced by α and β rays possess a different velocity of reverse trans formation under the influence of benzole and of high temperature —**P Lazarev** and **N Rodzevitch** The phenomena of ionisation of a gas during the discoloration of colouring substances in visible and in ultra violet light While there is no ionisation effect when cyanine is discoloured by the action of ordinary light, the action of ultra violet rays produces ionisation Similar results have been obtained with crystal violet —**A N Tsvetkov** The theory of physiological units The physiological unit is the

minimum quantity of the living substance which is still excitable Theoretical calculations show that the unit should be about μ^3 in size —A I Leskov The occurrence of *Buxus sempervirens* L in the northern Caucasus The forests in which boxtrees are found contain about 75 per cent of species of plants which must be regarded as Tertiary relics

Diary of Societies

FRIDAY FEBRUARY 14

GENETICAL SOCIETY (at John Innes Horticultural Institution Merton) at 2 30 —Experiments on *Primula Sinensis* —Miss de Winton and J B S Haldane Demonstration of the Genetics of Diploid and Tetraploid Forms —Dr C D Darlington Exhibition of Cytological Preparations of the Tetraploid —Dr F W Sansome Exhibition of Slides Illustrating Pollen Behaviour in the Tetraploid —J B S Haldane The Genetics of the Tetraploid

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 4 —E W Hey Groves The Hunterian Oration

ROYAL ASTRONOMICAL SOCIETY (Annual General Meeting), at 3 —President's Address on the Award of the Gold Medal to Dr J S Plaskett for his Valuable Observations of Stellar Radial Velocities and the Important Conclusions derived from them

PHYSICAL SOCIETY (at Imperial College of Science), at 5 —W E Summerhays The Diffusion Constant of Water Vapour —M C Johnson A Method of Calculating the Numerical Equation of State for Helium below 6 Absolute and of Estimating the Relative Importance of Gas Degeneracy and Interatomic Forces —F D Smith The Magnetostriction Constant for Alternating Magnetic Fields —Demonstration by D Kompson of A Working Model Illustrating the Mosaic Theory of the Compound Eye due to Altenburg

INSTITUTION OF ENGINEERING INSPECTION (at Royal Society of Arts) at 5 30 —Prof A F C Pollard Optical Aids to Engineering Inspection

ROYAL SOCIETY OF MEDICINE (Clinical Section) at 5 30

MALACOLOGICAL SOCIETY OF LONDON (Annual Meeting) (at Linnean Society of London) at 6 —H Watson (*a*) On the Anatomy and Affinities of *Plicatula* (*b*) On the Central Nervous System of *Spondylus* —J R le B Tomlin Some Preoccupied Generic Names II —Dr F A Schilder Remarks on Type Specimens of some Recent *Cypraeidae* —Exhibit *Cypraea Arabica* Group Eggs and Spawn of Terrestrial Mollusca

INSTITUTION OF LOCOMOTIVE ENGINEERS (Manchester Centre) (at 36 George Street Manchester), at 7 —K W Willans Water tube Boilers Suitable for Locomotives

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7 —G S Taylor Lantern Lecture

OIL AND COLOUR CHEMISTS ASSOCIATION (Manchester Section) (at Milton Hall Manchester) at 7 —R. G Daniels Common Sense and Nitrocellulose Lacquer

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (at Technical College Cardiff) at 7 15 —E A Rudge Timber as a Material of Construction

INSTITUTION OF AUTOMOBILE ENGINEERS (Coventry Centre) (at King's Head Hotel Coventry) at 7 30 —L H Pomeroy The Double six Engine

JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting) at 7 30 —Technical Film—The Manufacture of Staybrite and Stainless Steels

INSTITUTE OF METALS (Sheffield Local Section) (at Sheffield University) at 7 30 —S Matthews Recent Developments in Measuring Instruments

ROYAL SOCIETY OF MEDICINE (Ophthalmology Section) at 8 —F Moore Unusual Coloration of Scleroticа —R Pickard The Red Field and Optic Disc Resistance in Glaucoma and Allied Conditions

ROYAL INSTITUTION OF GREAT BRITAIN at 9 —Prof A F Pollard History *à la Mode*

ROYAL AERONAUTICAL SOCIETY (Yeovil Branch) (at Yeovil).—Flight Lieut H R W Waghorn The Schneider Trophy Contest of 1929

SATURDAY, FEBRUARY 15

ROYAL INSTITUTION OF GREAT BRITAIN at 3 —Rev G Cooke Tonality and Expression in Song Writing

MONDAY, FEBRUARY 17

VICTORIA INSTITUTE (at Central Buildings Westminster) at 4 30 —Brig Genl H Biddulph The Date of Ecclesiasticus

ROYAL SOCIETY EDINBURGH at 4 30 —Prof Carl Størmer Do the Wireless Echoes of Long Delay come from Space Outside the Moon's Orbit?

ROYAL GEOGRAPHICAL SOCIETY (at Lowther Lodge), at 5 —Lt. Col R. C F Schomberg Climatic Conditions in the Tarim Basin.

ROYAL COLLEGE OF SURGEONS OF ENGLAND at 5 —R H O B Robinson The Rôle of Short Circuit Operations in the Treatment of Cholecystitis

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7 —M E Fox, W E Warrilow, and others Discussion on The Nickel Iron Battery and its Uses —E C McKinnon and others Discussion on The Lead Battery and its Uses

INSTITUTION OF MECHANICAL ENGINEERS (Graduates Section—London), at 7 —W W S Robertson Strip Rolling Mills and Auxiliary Machinery

TEXTILE INSTITUTE (London Section) (at Barrett Street Schools), at 7 —R. J Steele Man's Quest for Fibres.

BRADFORD TEXTILE SOCIETY (at Midland Hotel, Bradford), at 7 30 —W Hunter Some Reflections on Wool and its Uses

INSTITUTION OF ELECTRICAL ENGINEERS (Mersey and North Wales—Liverpool—Centre) (at Liverpool University), at 7 30 —Capt. P P Eckersley Broadcasting by Electric Waves (Faraday Lecture).
ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8 —Prof P Abercrombie The Thames Valley Preservation Scheme.
ROYAL SOCIETY OF ARTS, at 8 —A B. Searle Recent Improvements in Methods of Brickmaking (Cantor Lectures) (1).
INSTITUTE OF CHEMISTRY (Edinburgh and East of Scotland Section) (jointly with Society of Chemical Industry—Edinburgh and East of Scotland Section) (at North British Station Hotel, Edinburgh), at 8 —Prof A. J Clark Drugs Manufactured by the Body
MEDICAL SOCIETY OF LONDON at 8 —Dr J W Thomson Walker Enlarged Prostate and Prostatectomy (Lettsomian Lectures) (1).

TUESDAY, FEBRUARY 18

ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15 —Sir William Bragg X ray Determination of the Structure of Cellulose and Similar Substances (2)
ROYAL STATISTICAL SOCIETY (at Royal Society of Arts), at 5 15 —Prof M Greenwood The Vaccination Problem.
ROYAL SOCIETY OF MEDICINE at 5 30 —General Meeting
ZOOLOGICAL SOCIETY OF LONDON, at 5 30 —H A. Gilbert Exhibition of Cinematograph Films of British Birds —O W Richards The British Species of Sphæroceridæ (Borboridæ Diptera).—S Zuckermann A Rhesus Macaque (*Macaca mulatta*) with Carcinoma of the Mouth —Dr Isabella Gordon African Fresh water Prawns of the Species *Caridina nilotica* Roux with Special Reference to the Nile Basin.—Dr C J van der Klaauw On the Tympanic Region of the Skull in the *Megatherium* —Dr J R Baker The Breeding season in British Wild Mice
ILLUMINATING ENGINEERING SOCIETY (at 15 Savoy Street) at 6 30 —W H Villiers Modern Incandescent Lighting in Kinema Studios
LONDON NATURAL HISTORY SOCIETY (at Winchester House, E C), at 6 30 —H R. Hewer The Colour of Fish and how they change it
INSTITUTION OF ELECTRICAL ENGINEERS (North Western Centre) (at Engineers Club Manchester), at 7 —J G Wellings and C G Mayo Instrument Transformers
INSTITUTION OF HEATING AND VENTILATING ENGINEERS (Associate Members and Graduates Section) (Manchester and District Branch) (at Milton Hall, Manchester), at 7 —F C Lant Kitchen Equipment
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN at 7 —Dr W Clark The Formation of a Photographic Image
INSTITUTION OF AUTOMOBILE ENGINEERS (Wolverhampton Centre) (at Engineering and Scientific Club Wolverhampton) at 7 30 —J H Pomeroy The Double six Engine
SHEFFIELD METALLURGICAL ASSOCIATION (at 198 West Street, Sheffield), at 7 30 —H E Kershaw Cobalt Magnet Steels

WEDNESDAY, FEBRUARY 19

ROYAL METEOROLOGICAL SOCIETY, at 5 —C K M Douglas The Cyclonic Depressions of November 16 and 28, 1928 —Discussion on memoir by Dr G C Simpson on The Distribution of Terrestrial Radiation
ROYAL COLLEGE OF SURGEONS OF ENGLAND at 5 —W McAdam Eccles Anatomy Orthodox and Heterodox in Relation to Surgery
ROYAL STATISTICAL SOCIETY (at Royal Society of Arts) at 5 15
NEWCOMEN SOCIETY FOR THE STUDY OF THE HISTORY OF ENGINEERING AND TECHNOLOGY (at Institute of Marine Engineers) at 5 30 —Eng Capt. E C Smith Pioneer Ships of the Atlantic Ferry
ROYAL AERONAUTICAL SOCIETY (at Institution of Electrical Engineers), at 6 30 —Dr W Georgii and Herr Stamer Gliding
INSTITUTION OF ELECTRICAL ENGINEERS (Sheffield Sub Centre) (at Royal Victoria Hotel, Sheffield) at 7 30 —Sir T F Purves Address
ROYAL SOCIETY OF ARTS, at 8 —Alfred Stevens Architect Sculptor Painter
FOLK LORE SOCIETY (Annual General Meeting) (at University College) at 8 —Presidential Address
ROYAL MICROSCOPICAL SOCIETY at 8 —Dr R S Clay and T H Court Early Achromatic Microscopes by James Smith —D V Daran (*a*) Coincident Images made use of in Mycological and Bacteriological Works with Reference to Single Spore Cultures (*b*) Reflection Magnification used for Physiological Experiments connected with Transpiration (*c*) Note on illuminating Objects for Microscopical Examination
ST PAUL'S ECCLESIOLOGICAL SOCIETY (at Royal Institute of British Architects) at 8 —H L Mann Baptismal Fonts

THURSDAY, FEBRUARY 20

ROYAL SOCIETY at 4 30 —*Papers probably to be read* —A C Davies Prof F Horton, and E Blundell Critical Potentials for the Excitation of Soft X Rays from Iron —Prof A V Hill A Thermal Method of Measuring the Vapour Pressure of an Aqueous Solution —M Nottage The Passive State of Adhesion
LINNEAN SOCIETY OF LONDON, at 5 —Symposium on Lampreys and Ostracoderms Speakers Sir Arthur Smith Woodward, Prof E S Goodrich, Prof D M S Watson, Dr C Tate Regan G R de Beer
ROYAL INSTITUTION OF GREAT BRITAIN at 5 15 —T A Joyce Architecture and the Industrial Arts of Pre Spanish America (2)
CHILD STUDY SOCIETY (at Royal Sanitary Institute), at 6 —Miss Muriel A Payne Homeless Children
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Colour Group—Informal Meeting) at 7 —Discussion on Some Technical and Practical Aspects of Colour Photography
BATLEY AND DISTRICT TEXTILE SOCIETY (at Batley Technical College), at 7 30 —Dr A W Stevenson Testing of Textiles.
INSTITUTION OF ELECTRICAL ENGINEERS (Irish Centre—Dublin) (at Trinity College, Dublin), at 7 45 —B A G Churcher and A. J King The Analysis and Measurement of the Noise emitted by Machinery
CHEMICAL SOCIETY, at 8 —Prof. T M Lowry and G Jessop The Properties of the Chlorides of Sulphur Part III Dielectric Constants Part IV Density and Surface Tension —G A C Gough and H King Trypanocidal Action and Chemical Constitution Part IX Aromatic Arsinic Acids Containing an Amide Group.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, at 8.15 —Dr V B Wigglesworth Some Notes on the Physiology of Insects related to Human Disease
BRITISH INSTITUTE OF RADIOLOGY, at 8 30 —Dr A E Barclay Mechanism of Swallowing —Dr J P Maxwell Osteomalacia and Fœtal Rickets —Dr J Muir The Irritable Colon
ROYAL AERONAUTICAL SOCIETY (Coventry Branch) (at Coventry) —Flight-Lieut. H R W Waghorn The Schneider Trophy Contest of 1929
ROYAL AERONAUTICAL SOCIETY (Yeovil Branch) (at Yeovil).—Squadron Leader J J Breen The Westland Wapiti in Iraq
SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (at Newport).—D Griffiths Tinplate Industry

FRIDAY, FEBRUARY 21

TEXTILE INSTITUTE (Lancashire Section) (at Textile Institute, Manchester), at 1 15.—J Smeaton Textile Specifications and their Preparation
ASSOCIATION OF ECONOMIC BIOLOGISTS (in Botany Lecture Room Imperial College of Science and Technology) at 2 30.—Dr W R Thompson Biological Control of Injurious Insects and Weeds
GEOLOGICAL SOCIETY OF LONDON (Annual General Meeting), at 3 —Presidential Address
MEDICAL OFFICERS OF SCHOOLS ASSOCIATION (Annual General Meeting) (at 11 Chandos Street W 1) at 5 —Dr G E Friend Some Notes on the Value of Clinical Dietetic and Physical Records in Public Schools (Presidential Address)
ROYAL SOCIETY OF MEDICINE (Balneology Section), at 5 —Dr J B Burt and others Discussion on Bath Reaction in Spa Treatment
BRITISH INSTITUTE OF RADIOLOGY (Medical Meeting), at 5 —Radiology in Gastrointestinal Diseases
ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 —E R Flint The Association between Gall Bladder Lesions and Hepatitis in the Human Subject
SOCIETY OF CHEMICAL INDUSTRY (Liverpool Section) (jointly with Manchester Section) (at Liverpool University) at 6 —J Twomey Flour Milling
NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute, Newcastle upon Tyne) at 6 —Rear Admiral W Scott Hill Powdered Coal for Ship Propulsion
INSTITUTION OF MECHANICAL ENGINEERS (Annual General Meeting) at 6 —Annual Report Discussion on Sixth Report of the Steam Nozzles Research Committee
INSTITUTION OF ELECTRICAL ENGINEERS (London Students Section), at 6 15 —S H Hart Paper Insulated Power Cables
TEXTILE INSTITUTE (London Section) (at Chemical Society) at 6 45 —F I Goodall Diagnosis of Colour Faults in Finished Goods
BEDSON CLUB (at Armstrong College Newcastle upon Tyne) at 6 30 —Sir James Walker Kolbe's Electrosynthesis (Bedson Lecture)
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group—Informal Meeting), at 7 —R H Lawton Pictorial Essentials
GEOLOGISTS ASSOCIATION (North East Lancashire Group) (at Blackburn Technical College) at 7 —Miss E J Wood A Visit to East Sutherland
JUNIOR INSTITUTION OF ENGINEERS at 7 30 —E P S Gardner The Application of Electric Welding to the Erection and Strengthening of Steel Structures
ROYAL SOCIETY OF MEDICINE (Obstetrics and Electro Therapeutics Section) at 8 —Special Discussion on The Position of Radium in Treatment of Gynæcological Conditions Openers M Donaldson and S Dodd Obstetrics Dr A E H Pinch and Dr J E A Lynham, Electro Therapeutics
ROYAL INSTITUTION OF GREAT BRITAIN at 9 —J B S Haldane Principles of Plant Breeding
SOCIETY OF DYERS AND COLOURISTS (Manchester Section) (at Manchester) —Prof McSwiney The Problem of the Fastness of Dyes to Perspiration

SATURDAY FEBRUARY 22

GEOLOGISTS ASSOCIATION (in Natural History Museum, South Kensington), at 2 30 —Dr W D Lang Demonstration of Palæontology and the Public
NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS (Newcastle upon Tyne) at 2 30
ESSEX FIELD CLUB (at West Ham Municipal College), at 3 —Celebration of 50th Anniversary
ROYAL INSTITUTION OF GREAT BRITAIN at 3 —W Rothenstein Nineteenth Century Painting in France and England (1)
OXFORD UNIVERSITY JUNIOR SCIENTIFIC CLUB.—Exhibition Meeting

PUBLIC LECTURES

SATURDAY FEBRUARY 15

HORNIMAN MUSEUM (Forest Hill) at 3 30 —Dr C Ainsworth Mitchell Tell tale Inks

MONDAY, FEBRUARY 17

UNIVERSITY OF LEEDS at 8 30 —S C Kaines Smith Aspects of Italian Painting (Succeeding Lectures on Feb 24 and Mar 3)

TUESDAY, FEBRUARY 18

GRESHAM COLLEGE, at 6 —W H Wagstaff Geometry (Succeeding Lectures on Feb. 19, 20, and 21)

WEDNESDAY, FEBRUARY 19

BELFAST MUSEUM at 8 —Miss W J Sayers The Dispersal of Seeds

FRIDAY, FEBRUARY 21

KING'S COLLEGE, at 5 30—Sir Rennell Rodd Survivals of Ancient Myth in Modern Greek Folk lore
SURVEYORS INSTITUTION at 5 30 —R A Watson Watt What is wrong with Wireless? (Lecture in connexion with Institution of Professional Civil Servants)

SATURDAY, FEBRUARY 22

HORNIMAN MUSEUM (Forest Hill), at 3 30 —Miss I D Thornley Sanctuary in the Middle Ages

Education for Environment[1]

UNTIL a few years ago the various local governments in British Africa could justly have been accused of indifference to the educational needs of the native peoples committed to their care Within the past few years, however, these same governments have given welcome evidence of their growing belief in education as the principal factor in the development of the capacities of the African peoples, and the need for supplementing the work of the various missionary bodies in the field of education They have been given much encouragement in their efforts to improve native education by the Advisory Committee on Education in the Colonies, which from its inception has had at its command the services of Major Hanns Vischer, who combines a genuine enthusiasm for education with an almost unique knowledge of the peoples of Africa and a sympathetic understanding of their needs Equally important has been the stimulus given to educationists in Africa by Mr Ormsby-Gore, Mr Jesse Jones and his associates, and the members of the Hilton Young Commission, all of whom have visited Africa within the past six years

In addition to the encouragement and stimulus from without, local governments find they are being urged from within to increase the educational facilities for the natives The natives themselves are almost clamorous in their demands for education, particularly 'education by the book', just as in India, since the capacity to read and write in the language of the dominant whites gives those who possess it a comfortable feeling of superiority over those who do not, especially as it carries with it the possibility of clerical or other semi professional work for government or for the trading community, and this work is the best paid

In striking contrast to the thirst for instruction exhibited by the Africans is the comparative indifference of the adult members of the white-settled communities in tropical and sub tropical Africa to the educational needs of white children In Kenya, Tanganyika, Nyasaland, Northern Rhodesia and Southern Rhodesia, there are many white children who are receiving practically no formal instruction at all, with the inevitable result that in each of these territories there is growing up a class of illiterate whites If this state of affairs is not soon ended, each of these territories will have its own 'poor white' problem, a problem which is already intense in the Union of South Africa and

[1] Southern Rhodesia Report of the Education Commission Pp ii+187 (Cape Town *Cape Times*, Ltd, 1929)

is causing much anxiety to the Union Government, for the 'poor white' is an unemployable, too ignorant and incompetent to be worth employing in a skilled capacity, but cursed with a superiority complex which prevents him from seeking employment in occupations regarded as only fit for blacks

Even those white parents in these territories who do send their children to the schools provided by the Government or voluntary bodies are almost without exception uncritical of the instruction given They are apparently pathetically content that such instruction should be almost identical in form and substance with that which is provided in the schools in Great Britain The majority of these white children will probably never leave Africa, essentially an agricultural continent, only a very few will proceed to a university, but their school studies are almost exclusively literary, more so than in the average grammar school in Great Britain, divorced from the realities of their environment and more likely to engender distaste for African life than to inculcate an intelligent appreciation of the significance of Africa in world economics and politics or a sympathetic understanding of its peoples, without both of which the assumption of leadership by the white minorities in Africa is an impertinent presumption

World opinion now demands that the whites in Africa should equip themselves for leadership An essential part of this equipment is the capacity to adapt themselves to the changed order of things The exploitation of the Africans by the immigrant races is no longer condoned by most of the governments in Africa The prosperity of the whites has to be based on something other than the misery of the blacks It can be attained by the development of the other natural resources of the continent The development of these resources, animal, vegetable, and mineral, is obviously dependent upon the quality of the co operation between the Africans and the whites, and this in turn is determined by the "right adjustment between the developing human organism and its surroundings" (Sir Richard Gregory's definition of education), whether the human organism be white or black

The school, it is true, is only one of the many forces at work to secure this adjustment, but it can be made the most potent of them all, if it provides "an education that works and moves entirely amid the facts and circumstances which make up the texture of life for its pupils", the aim set forth in the recent published report of the Education Commission, which was appointed at the beginning of 1929 by the Governor of Southern Rhodesia, Sir Cecil Rodwell, to inquire into the present system of education, other than native education, of that colony

This Commission surveys with admirable clarity and understanding the facts and circumstances of the life of the white settled community in Southern Rhodesia The white colonists, mainly of British stock, comprise less than 5 per cent of the total population, but they are the dominant political power The natives are docile and intelligent The Asiatic element in the population is very small as compared with that in the Union of South Africa or Kenya, and there is no Arab slave tradition as in eastern Africa It is a country of known great natural resources, both agricultural and mineral, and still greater possibilities It enjoys a fine climate It is situated in the midst of other great productive areas and is across the main lines of communication of the southern part of Africa Its political, economic, and social development is bound to exert a powerful influence on such development in other African colonies Also, since the determining factor in this development will be the white minority, it is all important that this white minority should be provided with an education which will fit it for its great responsibilities "In a community of white people set amidst a great black population", says the Commission, "the obligation to give every white child the most complete education which he is capable of receiving must be accepted at whatever cost"

The Commission considers that the main permanent objectives which a system of education for the white community in Southern Rhodesia must have in view are

1 "The continuance in full strength of the European inheritance"

2 The erection and maintenance of "a community that will be, in every aspect of its life, characteristically Rhodesian"

3 The development in the youth of the country of "the moral stamina to overcome the strong and subtle influences which, in a mixed society like that of Rhodesia, are constantly at work to sap the energies and weaken the moral tenacity of the privileged European"

4 "The development and wise use of the great natural resources of the country"

For the attainment of the first objective the Commission regards it as essential that not only teachers, but also other educating agencies, must continue to come from Europe, particularly from Great Britain, for this will ensure that the common store of achievement in literature and art and the

general apparatus of civilised life will be drawn directly from the source, to provide for those born in a hitherto barbarous land such as Southern Rhodesia "the best substitute for that rich background of long established civilisation which is the unconscious inheritance of every child in an older community" As regards the second objective, the Commission lays emphasis on the educative value of the study of 'the natural life of Rhodesia, its plants, animals, insects, climatic phenomena and so forth, the life of the natives which so intimately and subtly concerns the welfare of every child, the main industries the history of African settlement"

Regarding the third objective the Commission refers to "the danger of moral degeneration which threatens the youth of a country, where the services of others are so easily come by, and where the labour that serves the first needs of life is apt to be despised as menial and dishonouring" It recommends strongly that the expert aid of psychologists should be enlisted to investigate the influences on the life of white children through their many contacts with the native peoples, particularly in connexion with the attitude of the former to the latter The fourth objective will be best attained, it believes, by the multiplication of centres to provide facilities for training skilled workers, and better and more systematic co operation between the schools on one hand and organised industry and the technical departments of Government on the other

There follows a critical survey of the existing facilities for the education of the whites in Southern Rhodesia Various recommendations are made for the improvement of the system Southern Rhodesia is warned of the dangers of parochialism in education, and in particular is advised to lose no opportunity for friendly and fruitful co operation with the Union of South Africa Equally important are the suggestions made for the co operation of parents with school authorities The tendency on the part of parents to regard teachers as a class apart, and schools as institutions with no links with the homes of the scholars, is not uniquely a Southern Rhodesian phenomenon it is almost universal In this connexion the Commission's suggestion, that one means of promoting co-operation between parents and the education authorities would be by designing better home tasks for pupils, merits the most careful consideration in Great Britain

This is by no means the only need Southern Rhodesia and Great Britain have in common Where secondary schools exist in any British colonies, they appear to be based on home models, that is to say, the school curricula are designed to meet the needs of the universities to which only a very small proportion of secondary school scholars will proceed Parents and the public generally condone this, the former because they lack the courage to resist the demand by employing bodies for the stereotyped educational hall marks prescribed by universities The needed change will only be brought about, as the Commission states, by the public realising that Secondary schools should be regarded as the final stage of school education for the many rather than as the preparatory stage for the few" The need in all countries of the Empire is for the provision of a variety of secondary courses of equal status, not "one selected body of studies having a traditional pre eminence over others, any more than it can be regarded as the exclusive privilege of a select class" In any course, however, the Commission strongly recommends the inclusion of manual training and general science subjects, including biology What is surprising is the reaction of the Commission to the suggestion made by certain witnesses that some provision should be made in the white schools for the study of native languages The Commission says quite definitely that "the advantage to be gained from the introduction of native languages as a school study is not sufficiently great to justify the encroachment that would be involved on the time available for other studies"

A chapter of the report is devoted to agricultural education "Comparatively little has been done in Rhodesian schools to develop interest in the problems and the life of the countryside, and to produce what may be called rural mindedness" This the Commission attributes mainly to the fact that primary education in the Colony has been dominated by secondary education, and the secondary schools have been developed under teachers whose own education and training have been in the main on purely academic lines" But Rhodesian parents also object to their children "digging and hoeing", or doing any other form of manual work, since such occupations are regarded as 'Kaffir' work, too degrading for whites The result in Rhodesia as elsewhere is the progressive migration of the rural population to the towns

The staffing of the white schools in Rhodesia is adequate to the extent of generosity, but there is an undue proportion of untrained teachers, particularly in the secondary schools This the Commission regards as a grave defect It considers that both a university degree and training are essential for secondary school work, and backs its opinion

by the specific statement that the proportion of untrained teachers among the inefficient teachers is very much higher than the proportion of untrained teachers in the service as a whole This opinion is valuable, for it gives added authority to those members of the Colonial Office Advisory Committee on Education who have, for some years past, advocated the provision of professional courses, prior to appointment, for those graduates from British universities who wish to enter the education services in the Colonies A G CHURCH

The Philosophy of Spinoza and Leibniz

The Philosophy of Spinoza The Unity of his Thought By Richard McKeon Pp ix + 345 (New York, London and Toronto Longmans, Green and Co , Ltd , 1928) 25s net

Spinoza By Prof Leon Roth (Leaders of Philosophy Series) Pp xvi + 250 (London Ernest Benn, Ltd , 1929) 12s 6d net

Leibniz By Prof Herbert Wildon Carr (Leaders of Philosophy Series) Pp vi + 222 (London Ernest Benn, Ltd , 1929) 12s 6d net

THE new series of publications which, under the title of "Leaders of Philosophy", is being edited by Prof J L Stocks, ought to supply a want which has long been felt It is true that certain of the volumes contained in Blackwood's "Philosophical Classics", such as Adamson's monograph on "Fichte" and Croom Robertson's on "Hobbes", are in their way unique and of permanent value, but they were written nearly fifty years ago, and the last half century has been particularly fruitful in historical and critical work respecting all the philosophical systems that have influenced western thought There is, therefore, ample room for such a set of volumes as Prof Stocks contemplates, and with those that deal with Spinoza and Leibniz, the two greatest metaphysical thinkers of the pre Kantian period, the new series appropriately makes a start

At first sight, it is true, the individualism of Leibniz would appear to be diametrically antithetical to the universalism of Spinoza But, as Prof Roth points out, when it comes to a detailed working out of the two systems, the opposition tones down, and the similarities are at least as striking as the contrasts Prof Roth instances Leibniz's theories of soul, of pre-established harmony, of liberty, of perfection, as depending on specific features in Spinoza's doctrine, and he refers to the cardinal notion of activity (*esse = agere*) as being already involved in Spinoza's view of modal being He might, however, have gone further, and have shown that in the end both thinkers were confronted with precisely the same crucial issues

Prof Carr's account of the historical background of Leibniz's career, as also of the intellectual world of the last half of the seventeenth century, is extraordinarily well done, and forms a most fitting introduction to the later study In setting forth the various aspects of Leibniz's philosophy, there is room for considerable difference of emphasis, if not of interpretation For, although the philosophy is in itself essentially systematic, yet Leibniz himself left no single systematic exposition of it, and a connected view can only be obtained by drawing together what was put forward in detached letters and papers and essays Prof Carr justly lays stress upon the characteristics of unity and activity as defining for Leibniz the notion of real existence In contradistinction from the discreteness of a physical atom, consisting of *partes extra partes*, the unity of a real existent was the unity of an internal variety, and, in contradistinction from 'moving force', its activity was an 'implanted principle of change and persistence', involving effort, *conatus*, and that without external stimulus In other words, a real existent, or monad, was essentially psychical in character

It was, however, by the help of a further consideration that Leibniz was enabled to advance from this fundamental conception to the thought of an infinite plurality of monads—the consideration, namely, that psychical activity cannot be a mere flowing forth of unimpeded energy, because this would give no more manifestation of itself than would an elastic force which met with no resistance Accordingly, a monad must be both active and passive active, in order to exist at all, passive, in order to exist as an individual and to manifest itself as a centre of activity Hence the existence of one monad presupposed that of a world of monads with which it was in some way in relation, otherwise its unity would be impossible I think it is because Prof Carr makes no reference to the passive side of the monad's nature that Leibniz's philosophy, as he presents it, appears to be even more lacking in coherence than it really is For it was just this element of passivity, of limitation, of finitude, that Leibniz fixed upon to explain the appearance, in the life of the more developed monads, of the phenomenal world of sense experience In so far as the monad is passive, its representations are, he argued, obscure and confused, and what is obscure and confused *seems*

to it foreign, other than itself, *seems*, that is to say, to be external and material In brief, it was owing to the element of passivity in the constitution of the human mind that what is in truth non spatial appears to us as extended All this important side of Leibniz's teaching Prof Carr leaves untouched

The volume by Prof Roth is an able and scholarly piece of work, admirably adapted for those who are beginning the study of Spinoza It is divided into three parts, dealing respectively with Spinoza's life and general outlook, his philosophy, and his place in the history of thought Emphasising the fact that it was primarily as a moralist, bent on ascertaining the true goal of human endeavour, that Spinoza embarked upon metaphysical inquiry, Prof Roth unfolds with singular lucidity and well-balanced judgment the main results of the quest Nothing could be better in their way than the chapters that expound Spinoza's view of human beings as parts of Nature and the three grades which he distinguished of knowledge and conduct Where I think the author has been less successful is in his treatment of the metaphysical foundation of the whole system For bringing out the real significance of the metaphysic, it seems to me to be necessary to take account of the logical method that was being pursued, and, in particular, to be clear that it was with the notion of reason and consequent, and not with that of cause and effect as ordinarily understood, that Spinoza was proceeding Moreover, it is unfortunate, so far as his exposition is concerned, that Prof Roth seems unable to make up his mind as to whether what he calls "a recent gloss", which identifies what Spinoza described as 'extension' with physical energy, is justifiable or no, because the interpretation of the metaphysic depends to a large extent on which of these views is taken

Dr McKeon s book is planned on a more ambitious scale than Prof Roth's, and makes greater demands on the reader It is evidently the work of one who has laboured long and meditated much upon the philosophy which it seeks to exhibit as a unified whole The chapter, for example, on Spinoza's attitude towards experimental science is, in itself, a valuable contribution to Spinoza literature, and the account it contains of the controversy with Boyle ought to remove several prevalent misapprehensions So, too, in treating of Spinoza's doctrine of the passions, and of the function of the intellect in respect to the passions, the author has conscientiously striven to bring out the essential things and to play the part of a faithful expositor Again, however, the least satisfactory portion of the work is that which handles the metaphysic It is true Dr McKeon gives due prominence to the conception, fundamental for Spinoza, that while each finite thing is conditioned to exist and to act by another finite thing, which is its cause, and this again by another, and so on *ad infinitum*, yet all these finite 'modes' depend upon an ultimate ground in such a way that without it they can neither be nor be conceived Unhappily, however, in this context a serious printer s error has been left uncorrected on p 192, which altogether obscures the sense of the important quotation from "Ethics", i 17 But there is no adequate discussion of the notion of Substance, or of the relation of the 'modes' to Substance

In point of fact, it is impossible to make clear the metaphysic of either Spinoza or of Leibniz except by a critical treatment, mere exposition is not enough For the truth is that in the writings of both of them two inconsistent conceptions of infinite or ultimate being are struggling for expression, and the exigencies of their thinking occasion repeated oscillation between these two conceptions Spinoza, working on one hand with the principle *omnis determinatio est negatio*, conceived of Substance as purely indeterminate being, being in respect to which any positive characteristic would infringe its absoluteness, and then Substance was for him simply the unconditioned, that which must be in each particular 'mode', but in which the particular 'mode', *as particular*, could not be contained On the other hand, working with the principle that each finite 'mode' expresses the infinite in a definite and determinate manner, he conceived of Substance as *ens realissimum*, the sum of positive reality, and it is this conception which Dr McKeon and Prof Roth ascribe to him But the two conceptions are obviously incompatible, and, whichever alternative be selected, it is clear that the particularity of finite 'modes' is left without a ground

Similarly in the case of Leibniz On one hand, in accordance with the principle of continuity and with the notion of a graduated scale of existents, God was for him, as Prof Carr explains, the 'supreme Monad', the culminating term in the series of monads, although manifestly the difference between the 'supreme Monad' and any finite monad can no longer be a difference of degree only, as that between the other members of the series had been declared to be On the other hand, however, if each monad is essentially an individual,

and if individuality is dependent on the passive, limiting element, it is evident that God, as *actus purus*, as wholly devoid of passivity, cannot be a member of the series of monads, in the sense in which the term 'monad' had been originally defined For God then becomes what Leibniz himself once said a monad without passivity would be, "a deserter from the general order" Accordingly, we get the theory of a transcendent supramundane deity, who calls the world of monads into existence by an act of will, although what it is that converts the ideas of them in the mind of the deity into actual existents remains, from the necessity of the case, an inexplicable mystery And, indeed, as though conscious of this perplexity, Leibniz is not seldom to be found hinting at yet another view, according to which God is the source of all monads, that proceed from him by "a sort of emanation as we produce our thoughts", and then, while it is true the word is retained, the doctrine of monads would appear to have vanished, and that of *deus sive natura* to have taken its place

In fine, it has to be said that while Leibniz's philosophy undoubtedly contains features which are in advance of anything contained in the "Ethics", features that make for a more concrete conception of the world of existing realities, it proceeds largely by the help of like abstractions, and terminates in difficulties similar in kind to those which beset the path of Spinoza

Geometry of N Dimensions

An Introduction to the Geometry of N *Dimensions* By Prof D M Y Sommerville Pp xvii + 196 (London Methuen and Co, Ltd, 1929) 10*s* net

IT needs courage to produce a text book on the geometry of N dimensions The subject is not unduly difficult to those who take an interest in it, but most people have deeply seated prejudices which prevent them from taking it seriously into consideration One of the pioneers, Schlafli, in spite of his reputation in other branches of mathematics, failed to secure publication for his valuable memoir on hyperspace, and in fact it did not appear in full until after the author's death and fifty years after it was written

Let us examine the prejudices that are responsible for such obstruction, and consider how far they are justifiable The crudest form of prejudice is what may be called the 'common-sense' opinion that as space cannot have more than three dimensions, any consideration of hyperspace is obviously nonsense This opinion is due to a misapprehension as to the nature of the science of geometry, which certainly started as a form of surveying or 'earth measuring', but even in the time of the ancient Greeks had developed into a semi abstract science, to be deduced from a limited number of definitions and axioms We use the word semi abstract rather than abstract, because in the time of Euclid, and for more than two thousand years after him, it was supposed that the axioms were self evident truths about the real world Only one axiom, that concerning parallels, appeared to fall short of the high standard of the others No one doubted its truth, but it was scarcely self evident Many attempts were made to prove it, but all failed, and at last it was realised that a logical system of geometry (non Euclidean) could be constructed by starting with the denial of the parallel axiom This was the starting point for further progress, and by slow degrees it was recognised that there are an unlimited number of different kinds of geometry, each based on a certain set of axioms, which were really more or less arbitrary assumptions Moreover, the terms used in these geometries, such as straight line and plane, are not really fully defined, all that we know about them is that they are assumed to have the properties stated in the axioms

Geometry, then, is a sort of mental game played with an arbitrary set of rules, and by varying the rules we can get different kinds of geometries By varying only the parallel axiom we get non Euclidean geometry of three dimensions, by varying only another axiom we get Euclidean geometry of four or more dimensions, with which Prof Sommerville's book is concerned Of course we could also vary two or more axioms at once, giving for example non Euclidean geometry of four dimensions

Even when all this is recognised, it is still felt by many that hypergeometry, in spite of its logical self-consistency, is rather an unprofitable subject of discussion, like the medieval schoolmen's topic of how many angels could stand on the point of a pin, which, it should be remembered, had to be argued in strict conformity with the rules of logic from certain assumed premises Many scientific workers cannot escape from the opinion that hypergeometry can have no application to the geometry of the real world and cannot possibly have any application to physics or other branches of science Well, they are wrong Hypergeometry can be employed to discuss the properties of a cubic surface in three

dimensions, just as three dimensional geometry can be employed to discuss the properties of a quartic curve in two dimensions The bitangents of such a curve, as Geiser showed, can with advantage be considered as the projections of lines on a cubic surface Segre and other Italian mathematicians showed how, in an analogous way, a cubic surface can be considered as the projection of a four dimensional configuration

These researches have been brought within reach of English readers by Prof Baker's "Principles of Geometry", vol 4, in which he gives illustrations of the utility in geometry of the consideration of space of higher dimensions, especially of four and five dimensions As for physics, the importance in relativity of one particular kind of non Euclidean geometry (Riemannian) is now widely recognised Beginners in wave mechanics naturally assume that the three dimensions required in Schrödinger's theory of the motion of a single particle are the three dimensions of ordinary space, but as soon as we come to the case of two particles six dimensions are required Possibly this fact is not generally recognised As Eddington remarks, "Schrodinger's theory is now enjoying the full tide of popularity, partly because of intrinsic merit, but also, I suspect, partly because it is the only one of the three that is simple enough to be misunderstood" Many problems in thermodynamics require a number of dimensions (or degrees of freedom) exceeding three Coming to other sciences, R A Fisher's "Statistical Methods for Research Workers", a book addressed to biologists and others, is partly based on a use of the geometry of hyperspace The vagueness in the undefined terms of abstract geometry, which at first appears such a defect, is in fact an advantage, for it enables the science to be applied to entities which are very different from those considered in 'earth measuring'

After so lengthy a justification of the study of hypergeometry, the discussion of the details of Prof Sommerville's treatment must be very brief Of the three main branches of hypergeometry, metrical, projective, and differential, he deals fairly fully with the first and less fully with the second, possibly in view of Baker's treatment mentioned above The third aspect is not dealt with here, presumably because of the full treatment that it has received in connexion with relativity

Prof Sommerville's first four chapters explain the fundamental ideas of incidence, parallelism, perpendicularity, and angles between linear spaces Then follow two chapters on analytical geometry, projective and metrical The remaining four chapters, perhaps the most attractive part of the book, deal with regular figures in hyperspace, corresponding to the ordinary regular solids As a parting word to those who are still afraid that the subject is too abstract, we may mention that there are sixty diagrams and several references to sets of models

Scientific Prospecting

Applied Geophysics in the Search for Minerals By Prof A S Eve and Prof D A Keys Pp x + 253 (Cambridge At the University Press, 1929) 12*s* 6*d* net

THE location of mineral deposits and structures associated with the formation of minerals by their deformation of natural and artificial fields of physical force is a comparatively recent branch of geophysics, having its origin mainly in the economic requirements created by the War, and owing much of its development to the methods evolved during the War for the detection of unseen bodies The literature describing the various methods and apparatus used consists mainly of scattered papers in technical journals Notable attempts to coordinate this mass of material have been made by Ambronn, in his book on applied geophysics, translated from the original German by Dr M C Cobb ("Elements of Geophysics", see NATURE, July 13, 1929, p 52), and by the American Society of Mining and Metallurgical Engineers in the symposium "Geophysical Prospecting, 1929" The former work outlines the early history of applied geophysics and is a mine of information on related literature, but is written rather for the specialist than the general reader The latter work is a collection of essentially specialist papers on details of procedure and practical work

In the present work, Profs Eve and Keys have attempted to produce a concise and reasonably detailed text book on applied geophysics, suitable for physicists, geologists, and mining engineers—in short, for all who may in their practical work require a fairly complete knowledge of this subject It may be said that they have most decidedly succeeded in their difficult task They have carefully steered between the dubious imaginativeness of the 'popular' account, and the bleak inhospitality of the 'specialist' exposition, and have produced a sound, well-balanced treatise The engineer or geologist who is not thoroughly familiar with physical principles can yet derive a good working knowledge of these geophysical methods, and obtain a well-reasoned assessment of the relative applicability

of each method to a particular problem On the other hand, no difficulties are shirked, so that the physicist can obtain a correct insight into the basic principles underlying each method, and a satisfactory treatment of the methods and apparatus employed Where he wishes for further enlightenment, he is referred to extant papers written by specialists In this latter respect, however, the bibliographical references are not quite so extensive as could be wished, but further references appear at the end of the book

The first fifteen pages of the volume are devoted to an introduction containing a sketch of the history and principles of geophysical methods as applied to the location of minerals, and reveal the essentially practical outlook of the authors In Chap ii (pp 16-52) magnetic methods are discussed, and a very lucid account presented of the principles and apparatus employed Chap iii (pp 53 111) is concerned with electrical methods, and more particularly with earth resistivity measurements, to which the authors have given especial prominence based on their own field tests Their treatment of the potential methods is rather scanty, and would bear amplification in view of the amount of material available On the other hand, in Chap iv, which deals with electromagnetic methods wherein the variations in the electromagnetic field are measured by means of search coils, the authors have within the scope of 37 pages presented by far the best review of these methods that has yet appeared The vital problem of the elliptic polarisation of the field due to phase differences between the constituent electromagnetic vectors is boldly dealt with Chap v (pp 149 182) details the gravitational method, and, whilst thoroughly sound, would be improved by a few examples of the theoretical effects due to various simple types of structure and more details of quantitative interpretation made possible by consideration of such types Also the possibilities of isogam representation are rather scantily dismissed Seismic methods are discussed in the twenty seven pages of Chap vi, which is somewhat scurvy treatment for a method which has had such success in locating salt domes and other structures Lastly, Chap vii devotes thirty pages to radioactive, geothermal, and other methods which have, as yet, attained little practical value A bibliography and index complete the volume

The only real criticism possible is that the sections dealing with other methods might usefully have been expanded to the same degree as the ones devoted to electrical processes At the same time, the authors are to be heartily congratulated on the extraordinarily concise and attractive presentations of these methods which they have given The book should be invaluable to all interested in applied geophysics, including the specialist, who will turn to it repeatedly, especially when he wishes to readjust his horizon to 'practical politics' The price is very reasonable indeed for such a pioneer work, and the typography and illustrations are excellent This is not a book to lie at rest on the library shelf, but one to be read with enjoyment and then treated as a constant source of reference on all questions on this fascinating subject, which may truly be styled 'the new treasure hunting'

Our Bookshelf

Principles of Experimental Psychology By Prof Henri Piéron Translated by Prof J B Miner (International Library of Psychology, Philosophy and Scientific Method) Pp viii + 190 (London Kegan Paul and Co, Ltd, New York Harcourt, Brace and Co, 1929) 10*s* 6*d* net

Prof Piéron is known to psychologists in Great Britain as carrying on the work of Binet at the laboratory of the Sorbonne, and as the author of numerous monographs, as well as a treatise on thought and the brain, already translated into English In the work now translated, and added to the Library of Psychology and Philosophy, he defines psychology as ' a science of behaviour, of activity, of the co ordinated responses of organisms, considered in their totality" He thus holds a form of behaviourism, but his position is by no means identical with that of J B Watson

With his modified form of behaviourism as his guiding principle, Prof Piéron summarises the work of psychological science as he understands it, and the reader naturally finds that his exposition wears a very different aspect from that of the more orthodox treatise He first discusses reaction processes, affective, perceptive, and intellectual, and then gives valuable sections on levels of activity, and mental stages and types Very good examples of careful statement, based not on mere speculation but on scientific inquiry, are seen in what he has to say about masculine and feminine types, and about that much used but imperfectly understood term 'intelligence' Every page of the book shows, however, that it was well worth translating Only a master could have said so much in so few pages, and said it with such perfect clarity

The New Nature Study By F J Wright Pp 287 + 4 plates (London Thornton Butterworth, Ltd, 1929) 5*s* net

The term 'Nature study', as used by modern educationists, is not a synonym for natural history, or for what is vaguely called the study of Nature The primary concern of Nature study is not with the acquisition of knowledge, but rather with the cultivation of the scientific habit of mind by the logical correlation of natural phenomena The

selection of material suitable for investigation of this kind by young pupils is the teacher's main difficulty, but in practice it has been found that the behaviour of familiar animals and plants lends itself most readily to the method desired

For this reason it is, unfortunately, often supposed that Nature study is a dilute form of natural history, and Mr Wright's attractive book gives some countenance to the idea He frankly refers to the study as a 'hobby', the aim of which is to acquire knowledge The method of study he advocates is 'new' only in being based upon phenological recording It is well that attention should be directed to the great importance of the observational work organised by the Phenological Committee of the Royal Meteorological Society and not the least valuable part of the book is to be found in the appendices on "A History of Phenology" and "Phenology Abroad", which are respectively contributed by Mr J Edmund Clark and Mr I D Margary To phenological observers the book may be recommended as a gossipy, though sententious, guide to the identification of the plants and animals specified by the committee It is to be regretted that the manuscript was not revised by a competent botanist, who would have eliminated references to the petals of the wood anemone and to turnip bulbs, with various other unfortunate slips The volume contains a number of useful diagrams and five photographic illustrations

Enigmas Another Book of Unexplained Facts By Lieut Comdr Rupert T Gould Pp 320 + 8 plates (London Philip Allan and Co, Ltd, 1929) 12*s* 6*d* net

THOSE who have read Commander Gould's "Oddities" will be equally interested in his new book, which consists of a series of essays the object of which is to collect and digest the facts relating to a number of incidents which have not, up to the present, been satisfactorily explained He opens by discussing legendary giants, and sums up against the existence of any race of giants, although admitting that men of unusual tallness have been seen among the Patagonians The "Cry of Memnon", a sound emitted at or near sunrise by an Egyptian statue at intervals during a period of two hundred years is ascribed to unequal expansion of two portions of the stones forming the statue

Legendary longevity is another interesting topic, and it seems well established that Old Parr did really attain a remarkable age In discussing the controversies surrounding the first land sighted by Columbus in the Bahamas, and the various mythical discoveries of a north west passage from the Atlantic to the Pacific, the author is in his element, and is able to bring all his nautical experience to bear on the problem However, the detail is at times wearisome The mysterious ringing of bells is described but left unexplained The book closes with a discussion of the objective reality of the so called canals on Mars, from which it appears that the case for their artificial origin is 'not proven' L J C

Outlines of Zoology By Prof J Arthur Thomson Eighth edition, revised Pp xxviii + 972 (London Oxford University Press, 1929) 21*s* net

EVERY teacher of zoology thinks that, if only he had time, he would write the ideal text book for his students, and not a few have found the time The trouble usually is that so small a public outside the particular school concerned considers the work acceptable But in this most uncertain market Thomson's "Outlines of Zoology", written primarily for students in the Scottish universities, apparently meets some very real demand, for it goes steadily on to its eighth edition and undiminished popularity throughout the country

This book will never completely satisfy the student of comparative anatomy, but such is not its aim The author expressly intends it to be used as an accompaniment to other well known works As such it should be an invaluable member of the small library that even the most impecunious must possess, for in it he may learn to see the organism as a whole and living, and, as he reads, he will find guidance to certain vital aspects of his subject that many of the famous text books of zoology ignore

The present edition is some hundred pages longer than that published in 1921 To meet the needs of the more modern teaching, the author has expanded especially the chapters on function and development, the section on genetics has been increased, and one hundred additional illustrations have been inserted D L M

Chemistry in the Home By Dr J B Firth Pp 246 (London Constable and Co, Ltd, 1929) 5*s* net

THIS book, which is intended especially for housewives, welfare workers, and women teachers, is divided into two sections, the first dealing with the atmosphere, ventilation, water supply, heating, lighting, cleansing materials, disinfectants, and textile fibres, whilst the second is devoted to foodstuffs and beverages The subject matter is of very general interest, but the treatment is inadequate, the style of the writing being rather careless and unattractive Moreover, the title of the book seems badly chosen, since no attempt is made to develop the chemistry of the subject, chemical formulæ and equations being carefully avoided for the sake of "those who have no previous knowledge of chemistry"

The volume contains a highly condensed mass of facts, which are often merely enumerated without being adequately discussed Such technical terms as catalyst, saturated compound, enzyme, alkaloid, casein, etc, are likely to baffle the beginner, who may also be astonished to learn from the table on p 16 that the air from Hyde Park is richer in oxygen than that from other sources The expressions "hydrates of carbon" and "oxyhydrate of lead" are unfortunate, and the description of an amorphous substance in the footnote on p 227 is apparently meaningless Many scientific terms which are used in the text are omitted from the index

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications]*

The Classification of the Primates

IN his letter to NATURE of Jan 25, Dr Tate Regan uses the researches of my colleague, Mr Thornton Carter, as an argument against the validity of the classification of the Primates adopted by Prof J P Hill and myself In particular, he hints at the possibility of a complete dissociation of the Platyrrhine and Catarrhine monkeys, and their diphyletic origin respectively in America from Tarsioids and in Africa from Lemuroids

No one who is aware of the original researches bearing upon the problem, which have been carried on in this department by many investigators during recent years, will expect me to give in detail my reasons for rejecting his iconoclastic suggestion Tate Regan himself seems to overlook the fact that my letter in NATURE of Dec 7, 1929, was a commentary on the Croonian Lecture, in which J P Hill adduced new and decisive corroboration of the classification, graphically expressed in the accompanying diagram (Fig 1), which I have been expounding in NATURE and elsewhere for more than a quarter of a century

The significance of Thornton Carter's brilliant investigation, which Tate Regan has put to such strange uses, is worthy of much fuller study than has hitherto been given to it To economise space and to help in lucid exposition I have set out his results by inserting crosses and spots on the accompanying diagram The Lemurs (that is, the members of the sub order Lemuroidea found in Madagascar, as well as the Eocene fossils, E F L, found in America), and the monkeys and apes of the Old World, have enamel characterised by prisms with even edges and a scanty interprismatic substance In the Lemuroidea found in Africa (Galaginæ) and in Asia (Lorisinæ), the Tarsioidea (both recent and fossil, E F T), and the monkeys of the New World, the enamel prisms have undulating edges and the interprismatic substance is abundant Thornton Carter has emphasised the profound importance of the histological differences for purposes of classification If, however, we accept Tate Regan's reference to "the microstructure of the teeth as of primary importance in the classification of the Primates", and, ignoring all other evidence provided by anatomy, embryology, blood-reactions, and susceptibility to disease, break up the natural group of Pithecoidea into two independent phyla, American and African, we ought also to disrupt the Lemuroidea into two independent groups and exclude the African family Galaginæ and the Asiatic family Lorisinæ from the sub order, which would then be restricted to the Lemurinæ, Indrisinæ, and Cheiromyidæ of Madagascar, with the fossil Lemuroids of America and France

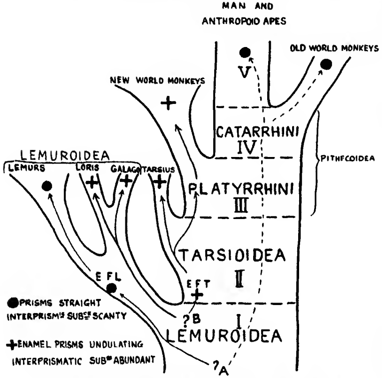

FIG 1 —Subdivision of the order Primates which developed in the Eocene period

The affinities of the Lorisiform Lemuroids, the Tarsioidea, and the Platyrrhine monkeys are admitted by most zoologists — all, in fact, except those who insist upon excluding the Lemuroidea from the Primates The complementary claim, which logically follows if we attach primary and exclusive importance to the evidence of dental histology, that the Mascarene Lemuroids are more nearly akin (than the rest of the Primates) to the monkeys and apes of the Old World, will be repudiated by the vast majority of zoologists, in particular by those mentioned in the foregoing sentence The facts of embryology given in Hill's recent Croonian Lecture, the new researches on the eye and brain, the well known evidence provided by the muscles and skeleton, the reactions of the blood, and in fact every department of comparative anatomy and physiology, go to establish the fact that, in the course of their evolution from remote Lemuroid ancestors, the Catarrhine monkeys must have passed through stages which are now known only in the living Platyrrhine monkeys and the Tarsioidea

The facts of comparative anatomy are fatal to such a classification as Tate Regan adumbrates Perhaps a concrete illustration will make this consideration plainer The outstanding factor in the progressive modification of the Primates is a profound revolution in the structure of the brain to give effect to the growing influence of vision and the transference of optic functions from the mid-brain to the cerebral cortex The morphological effects of this transformation are epitomised in the lateral geniculate body In the ancestors of the Primates the geniculate body consists of two nuclei of approximately equal size, the ventral linking the optic tract with the old optic mechanisms in the mid brain, the dorsal with the new cortical formation In the Tarsioidea, Pithecoidea, and Anthropoidea the growing influence of vision upon behaviour

is expressed anatomically in the expansion and differentiation of the dorsal nucleus, while the ventral nucleus undergoes progressive diminution until eventually it disappears Woollard has shown (*Brain*, vol 49, 1926, p 25) that the enhancement of the biological significance of the eyes in the Lemuroidea (not simply the Lemuridæ, but also the Lorisinæ) is expressed in a hypertrophy of the *ventral* nucleus of the geniculate body while the dorsal nucleus remains insignificant—the direct antithesis of what occurs in the ancestors of the monkeys, which is displayed also in *Tarsius* This is a certain indication of the fact that the Lemuroidea definitely left the track that led to the Tarsioid and Pithecoid conditions

This is merely one example (which might be paralleled by scores of others) to illustrate the impossibility of accepting Tate Regan's suggestion He tells us that he is interested in the subject from " the point of view of a student of geographical distribution " Yet he hints at the possibility of the evolution of the Catarrhines from a Lemuroid in Africa, where the only known Lemuroids (*Galago* and *Perodicticus*) have enamel of the Tarsioid type, that is, lack the very character upon which his speculation has been erected!

The outstanding fact established by Thornton Carter's and Hill's researches is the strength of the links that bind into one closely knit order all five stages in the progressive evolution of the Primates (1) Lemuroidea, (2) Tarsioidea, (3) the Platyrrhine Pithecoidea, (4) the Catarrhine Pithecoidea, and (5) the Anthropoidea

The distinctive characters of the enamel are already developed respectively in the Eocene fossil Lemuroids (E F L) and Tarsioids (E F T) found in America The earliest Eocene fossil Lemuroids (*Pelycodus* and *Notharctus*) reveal the same peculiarities of enamel as are found in the living lemurs of Madagascar The Lemuroids of Africa and Asia reveal the other type of enamel Whether this trait was inherited from some early Eocene (? or Cretaceous) ancestor common to the Loriso Lemuroids and the Tarsioidea (? B in Fig 1) or the common character developed independently in *Tarsius* and the Lemuroid *Galago* (by convergence in the two closely related descendants of one remote ancestor) there is no evidence to prove

Yet the suggestion is illuminating as a possible explanation of the appearance in the monkeys and apes (of the Old World) of the enamel type found elsewhere in the Primates only in the Mascarene Lemuroids If the tendency towards the emergence of this character developed in the remote ancestors of the Primates (? A in Fig 1), shortly before or simultaneously with the contrasted tendency, is it unreasonable to interpret the known facts by the statement that the former was held in check as man's ancestors passed through the Tarsioid and Platyrrhine phases and emerged again only when the Catarrhine phase was reached ?

In his great treatise on the Titanotheres (1914) and elsewhere, Henry Fairfield Osborn has repeatedly directed attention to the fact that in the divergent descendants of a common ancestor, characters which have been omitted in the immediate predecessors may emerge in both lines independently This variety of convergence is really the manifestation of a (previously latent) tendency which is due to a common origin The emergence in the Catarrhines of the type of enamel found in the Lemuroidea may be explained in this way The importance of this character is not diminished by the fact that it was suppressed during the Tarsioid and Platyrrhine phases of Primate evolution Its interest, moreover, is enhanced by the possibility that it may be linked with other properties of the organism Thus Tate Regan's contention seems to receive corroboration from the biometricians In their monograph, " A Study of the Long Bones of the English Skeleton " (1919), Karl Pearson and Julia Bell make the suggestion that the Cebidæ (Platyrrhine monkeys) are derived from a form approximating to the Tarsioidea and " the Simiadæ from a form approximating to the Lemurine group of the Lemuroids " (Sect II, p 314) For the reasons already given this suggestion is untenable Yet it may imply that the peculiarities of the enamel are linked in the evolution of the Primates with the proportions of the femur (and possibly also other features widespread in the whole organism)

The diagram (Fig 1) affords evidence that I have not overlooked the individuality of the Platyrrhine, Catarrhine, and Anthropoid groups, the distinctions no less than the mutual relations of which have been so lucidly expounded in J P Hill's Croonian Lecture

May I remind Tate Regan of what Huxley wrote in 1860 with reference to another pair of Primate groups " It would be no less wrong than absurd to deny the existence of this chasm but it is at least equally wrong and absurd to exaggerate its magnitude, and, resting on the admitted fact of its existence, to refuse to inquire whether it is wide or narrow " (" Man's Place in Nature ")

The 'Wave-Band' Theory of Wireless Transmission

MY friend Sir Ambrose Fleming raises an interesting question in his admirably clear article on page 92 of NATURE of Jan 18, no less a question than whether a mathematical alternative does or does not invariably correspond with some physical reality I am inclined to think that it does For example, there is some thing rotatory in a magnetic field, and whether the rotation of a plane of polarisation may be properly expressed as an acceleration of one circular component and the retardation of another, we have no better mode of expression until we know more So also I think that a sinuous wave of fluctuating amplitude may be rightly and exactly represented as if it were a band of neighbouring frequencies This is not obvious, but I would remind Sir Ambrose Fleming that the complete solution of the relevant differential equation for forced vibrations contains not only a simply periodic e^{ipt} term, but one with an evanescent exponential amplitude like e^{-kt} as well, and these latter periodic effects—depending as they do on the natural frequency of the receiver circuit (or on its range of possible frequencies)—though they rapidly die away—are of influence at the beginning and end of a wave series Dr Eccles tells me that those initial and final effects are called 'transients' by electrical engineers, and that is a good name for them

If we arrange for hyper selective reception we can deal with a continuous sine wave perfectly, but then it must be continuous, and have neither beginning nor end, and its amplitude throughout must be constant If the amplitude changes, as when a pure carrier wave is fluctuated by a microphone, it is no longer a pure sine curve, and then transient effects must be taken into consideration, for speech depends on those fluctuations of amplitude An excessively sharply tuned receiver working at the top of its peaks, so as to exclude everything except the last trace of a single pure tone, may exclude some of the transient effects also, and therefore not give clear reception Moreover, the amplitude of forced oscillation in the

receiver depends on the tuning, and the equation shows that this must allow for a slight departure from p on either side An alternative and different way of putting it, is to say that the fluctuations of sinuosity may prolong themselves by a sort of loud pedal effect, and cause indistinctness, unless some automatic damper can be applied This might conceivably be possible, by a relayed magnetic field, but mean while I suggest that the easiest way of taking the variations of amplitude into account is to express them as the boundaries of a wave band, to the whole breadth of which the receiver should be competent to respond

I understand from a private letter that Sir Ambrose Fleming intends to put this to the test of experiment, and see if extremely selective tuning which serves for bass notes will be equally effective for the high pitched harmonics essential for clear articulation, and vice versa How wide a band must be to achieve this under customary conditions, I do not know, and I hope he will tell us the result, at present he does not believe in a wave band at all, and his heresy must be of interest to all wireless experts I rather sym pathise with heresy, and hope he can substantiate this one of his, but I am exceedingly doubtful The heterodyne method, of regarding a sinuous dis turbance of fluctuating amplitude as a superposition of pure tones of slightly different frequencies, seems at first artificial, as he says, but it appears to corre spond with experience and if so, it is an interesting justification of the use of a trigonometrical equi valence familiar to many schoolboys, that "the sum of two sines is equal to twice the sine of half the sum into the cosine of half the difference"

OLIVER LODGE

Normanton House,
Lake, Salisbury, Feb 6

MR BEDFORD's letter in NATURE of Feb 8 appears to me to explain the difficulty raised by Sir Ambrose Fleming's article very clearly, but it is perhaps interesting to give the solution he indicates and evaluate the current set up in a receiver of frequency $r/2\pi$ when receiving a wave of frequency $p/2\pi$ modu lated to $q/2\pi$

If we write $p+q=\lambda$, $p-q=\mu$, the equation to be solved to give the disturbance in the receiver tuned to frequency $r/2\pi$ is

$$u+ku+r^2u=\frac{A}{2}\{\sin\lambda t+\sin\mu t\}$$

and the solution is

$$\frac{A}{2}\left\{\frac{\cos\epsilon}{k\lambda}\cos(\lambda t-\epsilon)+\frac{\cos\epsilon'}{k\mu}\cos(\mu t+\epsilon')\right\}$$
$$+Ce^{-\frac{kt}{2}}\sin\left\{\frac{\sqrt{(4r^2-k^2)}t}{2}+\alpha\right\},$$

where $$\cos\epsilon=\frac{k\lambda}{\{(\lambda^2-r^2)^2+k^2\lambda^2\}^{\frac{1}{2}}}$$

and $\cos\epsilon'$ has a similar meaning with μ substituted for λ, while C and α depend on the initial conditions These would normally be $u=u=0$, when $t=0$

Hence if $r^2=\lambda^2=(p+q)^2$,

$$\cos\epsilon=1,\quad \epsilon=0,$$

and the first term in the bracket becomes

$$\frac{1}{k(p+q)}\cos(p+q)t$$

Thus a receiver tuned to a wave of frequency $(p+q)/2\pi$ will be disturbed by the incidence of a wave of frequency $p/2\pi$ modulated to $q/2\pi$, and unless the ratio of the resistance to the inductance of the receiving circuit is large, that is, unless k is large, the disturbance will be considerable

Similarly, if $r=p-q$, a note of frequency $(p-q)/2\pi$ will be reinforced

If r is not equal to λ or μ, disturbances of frequencies $(p+q)/2\pi$ and $(p-q)/2\pi$ will still be produced in the receiver, but the amplitudes will be small

In any event, then, there will be the two side band waves which under favourable conditions will produce large effects R T GLAZEBROOK

Ballards Oak, Limpsfield
Surrey

IN his comments on my letter in NATURE of Feb 8 Sir Ambrose Fleming makes in rather categorical terms some statements that I think he would be in clined to modify if he could give this question a little more consideration I would remind him that an unduly selective receiver most certainly *does* fail to reproduce high notes in their proper proportion The effect is well known and observable at any time by anyone having a receiver in which the reaction is under proper control

I agree that many receivers are insufficiently select ive for practical purposes, but this neither alters the fact that a too highly selective receiver distorts by failing to pick up the side bands nor proves anything with regard to their non existence I would submit, in fact, that theory, laboratory experiment and all practical experience unite in proving that in every sense of the word the side bands do actually exist and that official regulations must necessarily be based on considerations of width of band as well as of amplitude CECIL L FORTESCUE

City and Guilds (Engineering) College,
Exhibition Road, London, S W 7,
Feb 12

THE correspondence in NATURE of Feb 8 (p 198) on the subject of the wave band theory of wireless transmission has directed attention to the question of the physical existence of the so called 'side bands' The following experimental results seem to indicate that these 'side bands' have, in every sense of the word, a very definite physical existence

(1) It is possible to isolate one of the side bands at the transmitting station and to transmit it separately, as in the system of single side band transmission used on the trans Atlantic telephony service

(2) Bown, Martin, and Potter (*Jour Instit Radio Eng*, vol 14, p 57) transmitted a modulated wave, received the carrier and the two side bands separately, and showed that the ionised regions of the atmosphere had treated the three component waves in different ways, as if they were physically distinct It appears that the atmosphere recognises the side bands as separate entities

(3) Rupp (*Zeit fur Physik*, **47**, p 72, 1928) used a modulation method to change the frequency of a light wave, so that it could pass through a selectively absorbing vapour which had stopped the unmodulated wave J A RATCLIFFE

Cavendish Laboratory,
Cambridge, Jan 31

THE correspondence on the existence of the Fourier components of a modulated carrier wave (NATURE, Feb 8, p 198) does not seem to have made the subject quite clear The existence of anything cannot be a mere matter of point of view, neither can the root of the matter be exhibited by the form of the mathe matical treatment necessary

The question at issue seems to be this Will a disturbance in the 'ether' due to modulating a carrier wave affect receiving circuits tuned to the Fourier components of the disturbance (regardless of whether the circuits be damped or not, that is, of low or high selectivity)? Sir Ambrose Fleming says no, in which case their existence is only mathematical fiction

The more orthodox argument seems to be as follows Fourier analysis shows that provided Huygens' principle of superposition holds, a disturbance in the ether due to a modulated carrier wave will be physically indistinguishable as regards amplitude variation from that due to the superposition of sine waves of certain amplitudes and frequencies It follows that circuits tuned to these frequencies will be affected, and therefore they can be said to exist

Since, however, in all reasoning from mathematical equations to the physical world we can never be sure that there are not other factors, not represented in the equations, which may affect the conclusions, we have to resort to experiment The practice of single side band suppressed carrier wave transmission, and the experimental resonant 'humps' referred to by Prof Fortescue, supply sufficient evidence for the existence of the Fourier components The value of Sir Ambrose Fleming's reply depends on whether makers of wireless sets, in their search for greater selectivity, have yet arrived at a point where the response in the audible range varies sufficiently to counteract the advantage gained by excluding interference from other stations

The Connexion of Mass with Luminosity for Stars

VERY remarkable and fruitful correlations have in recent years been detected, mainly at Mount Wilson, between the magnitudes of stars and their spectroscopic characteristics The interpretation that would naturally present itself is that magnitude can enter into relation with the radiative phenomena of the surface atmosphere only through the intensity of gravity at the surface, which when great flattens down a steady atmosphere far more than proportionately But if, following Eddington's empirical relation, total radiation of a star is a function of its mass alone, there must be more than this involved, for the radius of the star persists in this relation when expressed in terms of intensities of surface radiation and of gravity, the former determining the temperature roughly by itself Modern hypothesis, which treats confidently of an 'electron gas' with an atomic weight, as Ramsay boldly and prematurely proposed long ago, and subject to the Maxwell Boltzmann exponential energy formula for statistics of distribution, and to its consequences for the theory of dissociation of mixed gases in relation to pressure and temperature, has on the initiative mainly of Saha led to promising applications to stellar atmospheres, which are held to be of densities low enough at any rate not to forbid this mode of treatment

It would seem then to be necessary to conclude that these empirical spectroscopic relations on the surface require that the stellar atmosphere must be dominated to some degree by the remote steady interior of the star Accordingly, tentative theories of the internal constitution of the stars and their flux of radiation have been developed in much detail With Eddington the stars are perfect gases right down to the centre, though the density may there be hundreds of times that of platinum, as has apparently been verified for the case of the companion of Sirius—the high density involving the view at one time not unfamiliar that two atoms can occupy the same space, if the picturesque conception of atoms 'stripped' irrevocably to the bone is to be avoided, and the energy emitted as radiation would come from a dissociation or destruction of matter according to a law involving temperature On the other hand, it is insisted on by Jeans that the necessary radioactivity for the very long evolutions that are contemplated must be of constant and absolute intensity, else the star would explode and he has essayed to regard the star as 'liquid' in his investigations, apparently, however, implying a very imperfect gas rather than a special phase with its surface of sharp transition There are other theories of less statical type

A determined effort to shed off all such special hypotheses has been published very recently by Milne (*Monthly Notices R A S* for November, pp 17 53), which accordingly invites close attention and scrutiny The procedure is the natural one, to try to make continuity between the gases of the atmosphere subject to laws more or less already formulated, and a dense interior about which as little is to be assumed as can be helped He holds that it suffices merely to consider laws of internal density that are in mechanical equilibrium radially under internal pressure P, of which the fraction $(1-\beta)P$ is pressure of the internal field of radiation He does not find it necessary to consider how this field of radiation of pressure $(1-\beta)P$ is sustained against loss by outward flux for if he can arrive at results in terms of surface values that are valid for all such equilibrated densities whether otherwise possible or not, they must hold good for the one that follows the actual law of distribution whatever it may be

The essential feature, so far as a reader can extract the gist from the complication of formulas that seems to be inherent in these discussions, appears to be that the coefficient β, while increasing rapidly downward in the atmosphere in a manner which can be regarded as known, suddenly rises when a photospheric level is reached, altering with steep gradient until a nearly constant value of β is soon attained for the interior of the star and the same must apply only in less degree to the density ρ The condition of mere mechanical equilibrium of the interior is found to express the pressure at the interface between atmosphere and photosphere in terms of values at the centre and one quantity C arising from an integral along the radius involving the arbitrarily assumed law of density The expression for the atmospheric pressure at the interface involves the same constants in such way that on equating the pressures on the two sides of the interface they divide out of the result and only C remains This C is held, in the light unforeseen of comparison with facts, to be in some degree a characteristic constant for all the stars, and thus may be the new element beyond surface values, and without assuming anything about their interiors, that the law as formulated requires

This seems to be right enough in a general way, were it not that the formula for C involves the gradient of density within the star close to the interface, and thus its value must be very substantially changed, in absence of some verification to the contrary, by a very slight radial displacement of the surface which is chosen for that interface For inside the photosphere ρ is as θ^3, while P which is continuous across the interface is as $\theta^4\phi(\theta)$ so C^{-1} is as the value of $P^{-1}(d\rho/dr)^2$ in which the second factor is the internal gradient, at the surface If this consideration be correct it would appear that it is not legitimate to connect the chromosphere with the interior across a

sharp boundary surface, as if they were different phases of matter like a liquid and its vapour This conclusion would involve that the formula itself for C cannot be well founded and the reason can be assigned, that the transition from Milne's formula (21) to (22) is invalid because the interior gradient of ϕ at the interface is very large and cannot be neglected even when multiplied by θ Apparently one can only assert that the mass of the star involves the value of dP/dr within the photosphere and other quantities relating to the centre of the star, and the luminosity involves the value of P outside it, while the pressure P is continuous across a transition but not dP/dr

In any case, perhaps not much stress would be laid on the deduction The formula is regarded probably by its author as essentially an empirical result When the value of C had been adapted to two prominent stars, the Sun and Capella, it turned out in his hands, as he relates, to his astonishment, that it was a universal constant the same for all stars, and if so perhaps not connected with their interior constitutions at all

JOSEPH LARMOR

Cambridge, Jan 18

The Tesla-Luminescent Spectrum of Benzene

IN a recent letter to NATURE (Sept 7, 1929), Shapiro has pointed out that Riemann's wave numbers for the fluorescence spectrum of benzene (*Ann d Phys* **80**, 43, 1926) could be expressed by formulæ of the type

$$\nu = 37494 + 921n' - 998n_1'' - bn_2'',$$

where b takes the values 0, 600, 855, and 1180 in four series and n', n_1'', and n_2'' have appropriate small integral values

It may be of interest to note that similar formulæ hold for the band heads in the emission spectrum of benzene The experimental data were obtained during the tenure of a Commonwealth Fund Fellowship when I collaborated with Dr J B Austin in an investigation of the tesla luminescence spectra of organic compounds at Yale University The experimental method we employed differed in many respects from that of M'Vicker, Stewart, and Marsh (*J C S*, T **123**, 642, 1923) and gave much sharper band heads The error in the wave numbers, which were determined independently by Austin and myself, is probably less than 5 cm $^{-1}$, in the case of the reasonably strong and well defined bands Out of a total of about 110 bands recorded, 87 are satisfactorily accounted for by the formulæ

$$(a)\ \nu = 38613 + 924n' - 161n'' - 994n'''$$
$$(b)\ \nu = 37547 + 924n' - 161n'' - 986n'''$$
$$(c)\ \nu = 36476 + 924n' - 160n'' - 990n''',$$

where n', n'', and n''' have integral values from 0 to 6

It is noteworthy that the bands which are not accurately expressible by these formulæ are, without exception, situated in a part of the spectrum where the bands are faint, and consequently the accuracy of measurement is low It is in general true that the faint bands occur where the quantum numbers are simultaneously large In the most intense system—formula (*b*)—the band represented by the quantum number (0,0,0) is *not* observed faint lines are, however, represented by the numbers (0,0,1) and (0,1,0) The strong band heads in this system begin with an intense band and in approximate agreement with the wave number 37485 given by (1,0,1) This value corresponds to the $\nu_0 = 37494$ given by Henri ("Structure des Molecules", 1925)

There are five vibrational frequencies in the above formulæ, 924, 161, 986, 990, and 994, and these are in approximate agreement with similar constants in previous work on the various spectra of benzene Thus, 921 occurs in Henri's absorption work, and was used by Shapiro in the interpretation of the fluorescence spectrum 163 is a vibrational number employed by Riemann in formulæ for the fluorescence spectrum, and 164 5 occurs throughout M'Vicker, Stewart, and Marsh's work on the emission spectrum Finally, 987 appears in the formulæ of M'Vicker, Stewart, and Marsh, and 998 is given by Shapiro

In his letter to NATURE, Shapiro has directed attention to the agreement between his vibrational frequencies 600, 855, and 1180 and the Raman values 605, 853, and 1176 It may be noted that these numbers can be obtained with considerable accuracy by the combination of the vibrational frequencies in the present work In conclusion, these constants appear to be related to frequencies in the infra red spectrum of benzene, a result which has already been indicated by M'Vicker, Stewart, and Marsh in the case of their constant 164 5

It is hoped to publish elsewhere, in conjunction with Austin, a more detailed account of these results, as well as a description of the experimental investigation, and to extend the work to some benzene homologues for which new experimental data are available

Gaseous Combustion

IT is interesting to learn, from the letter which in conjunction with Mr W Davies he published in NATURE of Jan 25, that my friend Prof W T David seems to be coming round to an interpretation of his experimental work not unlike, although more advanced than, that which I suggested to him some five years ago as an alternative to the one of 'after burning', as distinguished from 'dissociation', which he had then put forward

Many of those present at the meeting of the Institution of Mechanical Engineers in London on Oct 24, 1924, when a paper by Prof David, on the "Missing Pressure and Heat Losses in Gas Engines" was read and discussed, will recall that he then regarded his work as proving that (to quote his words) "even under the ideal conditions obtainable in a closed vessel some 10 per cent of the gaseous fuel (coal gas) is unburnt at the moment of maximum pressure and that, therefore, incomplete combustion, in addition to increasing specific heat and heat loss, must be regarded as an important factor in limiting the pressure development"

In a written contribution to that discussion (*Proc Inst Mech Eng*, pp 806-9, 1924) I ventured to criticise such conclusion, saying that it was by no means the only possible interpretation of Prof David's experimental results, and that "Other equally probable alternative explanations (as, for instance, the assumption of a different distribution of the total energy, as between vibrational, rotational and kinetic kinds, of steam and carbon dioxide molecules at their moment of formation in the neighbourhood of the maximum pressure from that pertaining to the same molecules when in true equilibrium at the same temperature but at some considerable interval of time after their formation in combustion would equally well satisfy such facts" Also, I said that, so far as I could see, "there was nothing in the results of Prof

David's experiments which would enable them to discriminate at all between the possible alternative explanations Therefore whilst Prof David had preferred the particular interpretation put forward in his paper, he would have been equally justified by his facts in adopting (had he so chosen) another which some might regard as equally or even more probable than his own " In reply Prof David rejected my proffered alternative, because (he said) " the rate of partitioning of energy at the high temperature of explosion must be exceedingly rapid, and thermal equilibrium would set in almost instantaneously "

The alternative view, which I have long held, was further elaborated in the following paragraph on p 202 of the book on " Flame and Combustion in Gases", by Dr D T A Townend and myself in 1927 " When an explosive gaseous medium in equilibrium with its environment is ignited, a very sudden and violent change occurs, whereby new molecules are born at a high temperature in an intensely vibrational condition It is probable that, in the first instance and momentarily, the energy of the newly born molecules is mainly internal, and that a certain time interval must elapse, during which a rapid process of adjustment between the internal and kinetic energies occurs, before the medium re attains a steady state of equilibrium with its environment Indeed, it may be said that, in general, if T be the maximum mean temperature of the medium on explosion, in all probability its ' energy distribution state ' is momentarily different from that which would result had the products of combustion merely been heated up to that temperature In other words, it is generally agreed that the chemical changes occurring in flames and explosions do generate molecular systems whose energy is, in the first instance, largely vibrational, and that a definite, though it may be small, time interval must elapse before the energy becomes mainly kinetic, and the system re attains equilibrium with the environment "

In supposing the formation of 'long lived' molecules of carbon dioxide and steam of 'abnormal structure', Prof David and Mr Davies have extended the foregoing view much further than I would be prepared to go, especially as regards the 'long life' of the supposed metastable molecules Also, in saying that luminosity was manifested in their exploded gases " at a time long after that at which combination (as inferred from the chemical analysis of rapidly cooled samples) has been completed ", they would seem to have modified the former view about the so called 'after burning', in the sense that it seems now to be ascribed to incompleteness of the energy development (because of that held up in the supposed metastable molecules) rather than to that of the actual oxidation itself at the moment of maximum pressure

While reserving any further comments on the matter until after I have studied the evidence adduced in their forthcoming paper, perhaps I may be allowed to put in a caveat that in 'closed vessel' explosions the relative times for complete inflammation, for the attainment of maximum pressure, and for the cessation of luminosity in the medium, so largely depend upon such factors as shape and size of the enclosure and the occurrence of compression waves, that due caution should be exercised in judging the significance of particular experimental data, especially where the vessels used are larger than would allow of substantial homogeneity throughout the medium at the moment of maximum pressure

WILLIAM A BONE
Imperial College of Science and Technology,

Dissociation Energy of Oxygen Determined from the Pre-Dissociation of Sulphur Dioxide

THE absorption spectrum of sulphur dioxide vapour, which we are studying with Wieland, is composed of three electronic regions the first 3900 3400 which appears at high pressure (1 atmosphere and more in a tube of 100 cm), the second 3370 2450, which begins to appear at $p = 0\ 1$ mm , and the third from 2350 extending beyond 2000 for low pressures 0 02 10 mm

The first and third regions are made up of series of bands with a fine rotation structure The second region is also made up of bands with fine structure, but between 2550 and 2500 the bands become broad and diffuse The molecule is then pre dissociated

If we assume that this pre dissociation limit corresponds to the reaction

$$SO_2 \rightarrow SO + O$$

the heat of this reaction must be between 111,000 (2550) and 114,000 (2500) calories, the mean value being 112,500 cal

We have studied with F Wolff (*Jour Phys et Rad*, March 1929, p 81) the spectrum of SO, and have calculated from the convergence limit of the normal term the heat of normal dissociation, $SO \rightarrow S + O - 148{,}000$ cal

From the sharp limit of pre dissociation at 2792 which we obtained in the absorption spectrum of S_2 vapour, we can calculate the heat of dissociation of sulphur $S_2 \rightarrow S + S - 102{,}200$ cal This value is in agreement with the thermal determination 103,600 (Budde, *Zeit an Chem* 78, 169, 1912) The heat of reaction $\frac{1}{2}S_2 + O_2 \rightarrow SO_2$ is 83,000 cal (Ferguson)

The heat of dissociation of oxygen is, therefore,

$$148{,}000 + 112{,}000 - \frac{102{,}200}{2} - 83{,}000 = 126{,}400 \text{ cal } (5\ 5 \text{ volt})$$

This value is in good agreement with the determination which we made from the pre dissociation of NO_2 (128,000 cal) (NATURE, Feb 8, p 202)

It is very probable that the third absorption region of SO_2 presents also a pre dissociation limit corresponding to the reaction

$$SO_2 \rightarrow SO + O^*$$

We have found that the energy level of the metastable $1D$ oxygen is equal to 13,700 cm $^{-1}$ (NATURE, Feb 8) The second pre dissociation must then occur between 1800 and 1900 A We are studying it now with the vacuum spectrograph

Non-Disjunction Produced by Carbon Dioxide

THE abnormal mitoses seen in tissue cultures kept under high tensions of carbon dioxide were described in a communication in NATURE of Mar 17, 1928, p 420 (see also *Brit J Exp Path*, 9, 240, 1928) Fragmentation of the chromosomes and irregular migration of the chromatin to the centrosomes were seen, exactly similar to the mitotic changes observed many years previously in the eggs of *Ascaris megalocephala* subjected to radium (*Arch Middx Hosp*, 30, 98, 1913) These observations suggested that carbon dioxide might produce hereditary disturbances, when applied to germ cells, analogous to those produced by X-rays and radium In order to test this, observations on non disjunction in *Drosophila* have been made, in which newly hatched virgin red-eyed flies were subjected to either pure carbon dioxide for a few hours,

or to varying mixtures of air and carbon dioxide for longer periods of time They were then crossed with white-eyed males, and allowed to breed

In the experimental series, 9 exceptional sons in 3930 sons were found, in the corresponding controls 2 exceptional sons in 4880 Using the formula given by Karl Pearson (*Phil Mag*, 6th Series, 13, 365, 1907), $\sqrt{\frac{m}{n}(p+1)\left(1+\frac{m}{n}\right)} \times 0\,6745$ equals the probable error of difference, it is calculated that the difference between the mean number of exceptional sons expected from the control series and the actual number of exceptional sons of the carbon dioxide treated flies is equal to 4 66 times the probable error Among the corresponding daughters two *gynandromorphs* were found, both in the experimental series, none in the controls

In view of this effect of carbon dioxide on non disjunction, there is reason to think that it will produce other chromosomal disturbances, and alter germ cells in a manner similar to X rays, and I write in the hope that those who have facilities for the study of the production of mutations will give carbon dioxide a trial For those who are working upon 'the somatic mutation' hypothesis for cancer these results are of special interest, in that they provide a way for the production of somatic mutations other than by X rays and radium J C MOTTRAM

Mounting Medium for Film Sections

IN the photomicrography of film sections for the purpose of examining the edge of the section, difficulty is encountered in the case of nitrate base when ordinary benzol- or xylol balsam is used as the mounting medium, owing to the refractive index of the medium being very close to that of nitrate film A mounting medium of high refractive index ($N_D = 1\,591$) suitable for photomicrographing sections of nitrate film is made up as follows

10 cm^3 of alphabromonaphthalene is added to 15 gm of dried Canada balsam in a glass stoppered or 'balsam' bottle The mixture is heated on the water bath until the balsam has melted Gentle agitation will then cause the liquid to become homogeneous

This highly refracting balsam will find other applications in microscopy, for example, for use with Diatomaceæ and micro crystals

For the photomicrography of sections of acetate film, benzol or xylol balsam is satisfactory

A Probable Band Spectrum of Neon

HERZBERG has recently suggested (*Zs f Phy*, vol 57, p 626) from theoretical considerations that two excited neon atoms may combine to form a neon molecule, just as two excited helium atoms combine to form a molecule of helium, yielding a band spectrum discovered by Goldstein in 1913, and the subject of numerous researches in recent years by Curtis, Dieke, Takamine, Weizel, and others It may be interesting in this connexion to note that while working with a neon discharge tube supplied by Leyboldts Nachfolger, Cologne, I obtained about a year ago a number of bands in the red which appear to be due to neon molecules The bands appeared under a transformer discharge, and disappeared when the discharge was sent from an induction coil

The bands are rather peculiar, as they show no head, and consist of a number of lines at equal frequency intervals Apparently the Q branch is entirely missing, only the P and R branches are developed The bands are approximately at 7393, 7208, 7063, 6963, 6847, and seem to be associated with strong red lines of neon The frequency difference between the successive lines is approximately 6 units, from which the moment of inertia comes out to be 18×10^{-40} cm^{2}gm, and the distance between the neon atoms comes out to be of the order 1×10^{-8} cm The distance between the atoms of the Na_2 molecule is stated by Birge to be $2\,33 \times 10^{-8}$ cm Since the electron in the excited neon comes from a closed shell, its distance from the nucleus should be much less than that of the electron in Na_2, and this is in accordance with my result D G DHAVALE

Preparations of Protozoa and Algæ

WITH reference to Dr Ll Lloyd's method of obtaining preparations of protozoa and algæ (NATURE, Jan 18, p 91), I have used a similar method since 1926 for the study of growths of sessile algæ I demonstrated this method in a paper to Section K (Botany) of the British Association at the Glasgow meeting in 1928

Glass microscope slides 1 inch wide and of the suitable length are fitted in a metal photograph printing frame and either wired (or chained) on the bed of the river or buoyed at a certain level with corks After a given period the frame is lifted out and the slides can be fixed and treated in the same manner as other microscopic preparations

I believe the first to use glass slides for this kind of work was Nauman (see *Ber Deutsch Bot Ges*, 37, 76 78, 1919) R W BUTCHER

Wild Birds and Butterflies

APROPOS of the recent discussion in NATURE as to the frequency with which butterflies are eaten by birds, the following extract from *The Emu*, 29, Pt 3, October 1929, p 88, may be of interest The writer is Mr M S R Sharland, Melbourne, and the species of bird is the dusky wood swallow (*Artamus cyanopterus*) "When almost full fledged they (*i e* the nestlings) were fed at frequent intervals on butterflies This was the first time I had noticed butterflies being included in the menu of either adult or young birds The wood swallow is evidently immune from any objectionable sensations to the palate which the butterfly may cause, but these insects seem to be shunned by most birds" J B CLELAND

The Function of Phosphate in Alcoholic Fermentation[1]

By Prof ARTHUR HARDEN, F R S

THE discovery that phosphates play an essential part in alcoholic fermentation arose out of an attempt by the late Dr Allan Macfadyen to prepare an anti zymase by injecting Buchner's yeast juice into animals As a necessary preliminary to the study of the effect of the serum of these injected animals on fermentation by yeast juice, the action of normal serum was examined It was thus found that this exerted a two fold effect, in its presence the action of the proteolytic enzymes of the yeast juice was greatly diminished, and at the same time both the rate of fermentation and the total fermentation produced were considerably increased

In the course of experiments made to investigate this phenomenon, which it was thought might have been due to the protection of the enzyme of alcoholic fermentation from proteolysis by means of an anti protease present in the serum, the effect of boiled autolysed yeast juice was tested, it being thought that the presence of the products of proteolysis might also exert an anti proteolytic effect As my colleague Mr Young, who had by this time joined me, and myself had fortunately decided to abandon the gravimetric method chiefly used by Buchner in favour of a volumetric method which permitted almost continuous observations, we were at once struck by the fact that a great but temporary acceleration of the rate of fermentation and an increase in the carbon dioxide evolved proportional to the volume of boiled juice added were produced This was ultimately traced to the presence of two independent factors in the boiled yeast juice, a thermostable dialysable coenzyme, now often known at the suggestion of Euler as co zymase, and inorganic phosphate

With regard to the phosphate, subsequent experiments showed that in all fermentations brought about by preparations obtained from yeast the presence of phosphate is absolutely essential Leaving aside the question of living yeast for consideration later on, three different types of fermentation can be established (Fig 1, curves 1, 2, and 3) with such preparations

(1) A relatively rapid fermentation (Fig 1, curve 1) in which sugar is decomposed into carbon dioxide and alcohol and simultaneously inorganic phosphate is converted into an ester (or esters) of a sugar which accumulates The rate rises to a maximum, and when the supply of inorganic phosphate ceases, the rate of fermentation falls, the accumulation of ester also naturally ceases and the fermentation passes into Type 2

(2) A relatively slow fermentation (Fig 1, curve 2) in which the rate at which fermentation occurs is controlled by the rate at which inorganic phosphate is supplied by the hydrolysis of the phosphoric esters present in the system by the phosphatase also present This inorganic phosphate is alternately reconverted into a sugar phosphoric ester and again liberated by hydrolysis, and thus fermentation proceeds at a steady rate in the presence of available sugar without any permanent increase in the amount of inorganic phosphate or of phosphoric ester present This is the type of fermentation which goes on when sugar is added to an active preparation from yeast and the process is allowed to proceed until a steady rate is obtained In some preparations, depending on the amount of phosphatase present, the rate of fermentation is increased to some extent if more of the sugar phosphoric ester is added or produced (Boyland, *Biochem J*, 23, 219, 1929), but this soon reaches a limit If inorganic phosphate be added, the fermentation passes into Type 1 If sugar fails, inorganic phosphate appears and ultimately (under

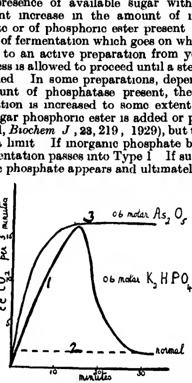

FIG 1

favourable conditions) the whole of the sugar phosphoric ester is hydrolysed, its sugar moiety fermented and the whole of the phosphate liberated in the inorganic form

(3) If now into a fermentation mixture in which a Type 2 fermentation is proceeding an additional quantity be introduced of a phosphatase, capable of hydrolysing the sugar-phosphoric ester and thus increasing the rate of supply of inorganic phosphate (Harden and Macfarlane, unpublished results), the rate of fermentation also rises If a sufficiently active preparation of phosphatase could be added so that the sugar phosphoric ester was decomposed as rapidly as it was formed, a rapid fermentation would ensue, unaccompanied by accumulation of phosphoric ester This has not yet been accomplished directly, but an indirect method of attaining the same end is available, inasmuch as arsenates have been found to have the power of greatly stimulating the effect of the phosphatase

This observation was in reality the undeserved reward for thinking chemically about a biochemical problem In many chemical reactions the type of compound concerned is the main fact of importance, arsenates react like phosphates, potassium may be replaced by sodium, iron by nickel or cobalt Biochemically, the difference between potassium and

[1] Address delivered at Stockholm on Dec 12, 1929, on the occasion of the presentation of the Nobel Prizes.

sodium may be the difference between life and death, and when iron is not used in a respiratory pigment it is not replaced in Nature by nickel or cobalt, but by copper or vanadium So, also, arsenate does not play a similar part to phosphate in fermentation, but acts in an entirely different manner On the addition of a suitable amount of arsenate a rapid fermentation (Fig 1, curve 3) occurs comparable in rate with that of Type 1, but differing from this in that the rate is permanently raised and that no accumulation of the sugar-phosphoric ester occurs Under optimal conditions the addition of inorganic phosphate does not produce any significant rise in this rate of fermentation, as the rate of fermentation is controlled in these circumstances by the concentration of the fermenting complex (enzymes + co-enzyme) Arsenate, on the other hand, does not increase the maximum rate in fermentation of Type 1, as the supply of inorganic phosphate is already optimal

Without making any assumption as to the exact nature of the phosphoric ester actually produced, the changes so far considered may be illustrated by the two equations originally proposed by Harden and Young for the case in which only hexosediphosphate is formed, the first representing the evolution of carbon dioxide and production of alcohol, accompanied by the accumulation of ester, and the second the hydrolysis of this ester with liberation of a hexose and mineral phosphate

$$\text{I} \quad 2C_6H_{12}O_6 + 2Na_2HPO_4 = C_6H_{10}O_4(PO_4Na_2)_2 + 2H_2O + 2CO_2 + 2C_2H_6O$$

$$\text{II} \quad C_6H_{10}O_4(PO_4Na_2)_2 + 2H_2O = C_6H_{12}O_6 + 2Na_2HPO_4$$

Equation I represents the condition of affairs in a fermentation of Type 1, Equation II that in a fermentation of Type 2 In the presence of arsenate, the hydrolysis of hexosephosphate according to Equation II proceeds sufficiently rapidly to supply phosphate at such a rate that Equation I proceeds at maximum velocity

FERMENTATION BY LIVING YEAST

A striking feature of fermentation by yeast preparations is that it proceeds much less rapidly than fermentation by a corresponding amount of living yeast Thus Buchner's yeast juice ferments at only about 1/20 1/40 of the rate of the yeast from which it is derived

The fact that the rate of fermentation of such a juice can be raised in favourable circumstances some ten to twenty times simply by increasing the supply of phosphate seems to me to indicate clearly that a large fraction, at least half, of the fermenting complex of the yeast has escaped injury in the preparation and has passed into the juice, but that the mechanism for the supply of inorganic phosphate has been to a large extent destroyed Neither arsenate nor phosphate has an accelerating action on the rate of fermentation by living yeast This may be due to the fact that the supply of inorganic phosphate in the interior of the yeast cell is already optimal, but some doubt exists as to whether or not these salts freely penetrate the cell If, however, as seems to me probable, it is true that in the making of preparations from yeast it is the phosphate-supplying mechanism that is thrown out of gear, it becomes an object of inquiry in what way this is brought about

Several possibilities present themselves As suggested for the fermenting complex itself by Euler and his colleagues, the phosphatase may in large part be combined with the cytoplasm and thrown out of action when the cell is killed Another possibility is that in the cell the action is localised and that disorganisation of the cell leads to less favourable conditions (for example, concentration, presence of inhibitors, etc) and to lessened rate of action There is some evidence for this, since the amount of phosphatase present, as judged by the normal rate of fermentation (Type 2), seems to diminish as the disorganisation of the cell becomes more complete Thus dried yeast and yeast dehydrated with acetone ferment sugar (Type 2) more rapidly than yeast juice, although when phosphate

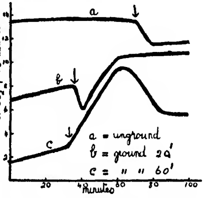

FIG 2

is freely supplied they all cause fermentation at about the same rate Again, some labile substance which acts as an accelerator of the phosphatase may be inactivated by the various modes of treatment (grinding, drying, treatment with toluene or acetone, etc) to which the cell is subjected

The process least likely to activate such an accelerating substance is probably that of Buchner, but the possibility also exists that such a substance, if present, might be adsorbed and thus removed from the juice by the large quantity of kieselguhr employed

Experiments (not yet published) have recently been made in my laboratory by Miss Macfarlane to find out at what stage in the process the change occurs and whether a juice richer in phosphatase could be obtained by modifying the process of grinding and pressing out It appears, however, that simple grinding with sand produces a change of the same order as that observed in Buchner's yeast juice The experiments were made by grinding a mixture of sand and yeast for different times and testing the rate of fermentation and response to phosphate at intervals of the whole mass without pressing out (Fig 2)

These curves show the rate of fermentation of

2 gm of yeast + 2 gm of sand in 20 c c of 10 per cent fructose at 30°, (*a*) without grinding, (*b*) after grinding for 20 minutes, and (*c*) after grinding for 60 minutes At the point marked with an arrow 0 6 c c of 2*M* potassium hydrogen phosphate was added The curves show that the longer the period of grinding, the lower the rate of fermentation and the greater the response to phosphate Here again the total loss of fermenting power was only small

Minor differences were observed when different substances were substituted for the kieselguhr used by Buchner, the most active juice, for example, being obtained by the use of calcium carbonate, whereas barium carbonate yielded totally inactive material Further investigation may possibly throw more light on this aspect of the question

I have assumed up to now that the processes in the living cell are essentially of the same kind as those which occur in the various preparations made from the dead cell, but differ from these mainly in the relative intensity of some of the reactions, and I know no valid argument against this assumption

The cycle undergone by the phosphate in the series of changes which constitutes ordinary fermentation clearly consists in the alternate formation of a phosphoric ester and the hydrolysis of this to free phosphoric acid A simple calculation based on the phosphorus content of living yeast shows that the whole of this phosphate must pass through the stage of phosphoric ester every five or six minutes in order to maintain the normal rate of fermentation, whereas in an average sample of yeast juice the cycle, calculated in the same way, would last nearly two hours

(To be continued)

Hybrid Vigour and Fibre Production

MAN may not consume more vegetable food per capita now than in days past, but it is certain that the amount of vegetable fibre employed to clothe him, and to spread before his eyes the printed word, increases from year to year, and the subject of vegetable sources for our cellulose supplies is frequently canvassed as a result

In a very interesting and suggestive chapter in their text book "Genetics in Relation to Agriculture", Messrs Babcock and Claussen, two distinguished geneticists of the University of California at Berkeley, point out that rapid vegetable growth, in all kinds of plants is frequently very marked in the first generation hybrid offspring of crosses between species or varieties, it is impossible to define the procedure too accurately in view of the confusion that surrounds the taxonomists' definition of a species, but these authors were referring to a familiar phenomenon which very early received attention in the history of breeding experiments

The rapid production of cellulose for the voracious maw of the printing press depends upon the rapid growth of the plant, and in America, following the lead of such geneticists as Babcock and Claussen, the foresters are exploring the possibilities of hybridisation as the source of an F_1 generation of trees which shall grow more quickly than either parent The intention, of course, is to propagate such a vigorous seedling when procured by vegetative means In such a 'clone' of vegetatively propagated trees the hybrid vigour of the original plant may be expected to persist, and when, as in the case of the paper pulp industry, the essential point is quantitative yield of wood, to a certain extent regardless of quality, the problem is relatively clear-cut and there seems considerable possibility of attainment of the practical end in view

Where, however, plants of briefer duration of life are concerned, and where each new generation of plants is raised from seed, at first sight the possibility of obtaining more-vigorously growing plants as the result of hybridisation seems very remote As is well known, in subsequent generations, the Mendelian growth factors, combined in the F_1 hybrid, usually segregate independently and there is little likelihood of many seedlings of the new F_2 generation containing that happy summation of dominant factors contributing to vigorous growth which were fortunately combined by the cross making the F_1 plant However, in recent years numerous cases have come to light where many factors, thus first brought together in a cross, have remained together during subsequent generations as the result of that obscure process controlling the fusion and sorting of the constituents of the chromosome which are grouped under the term 'linkage' It is, therefore, perhaps worth pointing out that at the present time two plants which are or have been under trial as sources of fibre may represent the offspring of a natural hybrid

Prof F W Oliver, now enjoying his well earned rest from the Department of Botany, University College, Gower Street, by taking charge for a short period of the Botanical Department of the University of Cairo, has frequently directed attention to the vigorous growth of one of these plants—rice grass or cord grass, *Spartina Townsendii*

Three articles upon this grass, upon its distribution, its use in reclaiming maritime muds and resisting foreshore erosion, and as a fodder, etc, appeared in the *Journal of the Ministry of Agriculture* recently, and were reprinted by the Ministry as Miscellaneous Publication No 66, whilst, during the War, experiments were made with this plant in paper making As Prof Oliver points out in his contribution in these articles, we are still uncertain of the accuracy of the assumption that this grass arose as a hybrid between the species *S alterniflora* and *S stricta*, experiments made in crossing the putative parents having so far been without result If a hybrid, it is at least remarkable that no segregates have been discovered during the fifty years in which the spread of *S Townsendii* has now been observed

In the other case, the plant in question is under much more vigorous exploitation as a fibre plant 'Brotex' was referred to in NATURE of Mar 9, 1929 Its botanical history is far less known than

that of *Spartina Townsendii*, as its examination has been conducted for commercial rather than scientific ends We are told, however, that this malvaceous plant is a hybrid biennial which comes true to seed and can be grown successfully in Devonshire, with vigorous production of fibre The Brotex Company, of 10 New Burlington Street, London, has issued a booklet containing some very striking photographs of the plant under cultivation at Totnes, Devonshire There seems little doubt also that a valuable fibre can be obtained from the plant, it has still, of course, to establish its place as a commercial source of fibre

Again, we seem to be confronted with a case of vigorous cell wall production by a plant of hybrid origin If the claims for the plant are justified and this vigour of growth maintained in subsequent years, as in the case of *Spartina*, once more the question arises whether linkage has established amongst the hybrid offspring a stable and vigorous race of plants

Another alternative in such cases has to be borne in mind, and will doubtless form the subject of future investigation In *Citrus* and in many other genera of plants, it is possible to maintain a hybrid race intact, although propagating by seed, because these seeds are actually asexually produced, so that though 'seed' is planted, the plants are actually members of one vegetatively propagated 'clone'

The whole subject of the utilisation of hybrid vigour, for fibre production as for fruit and vegetable production in the service of man, is a fascinating topic fraught with great practical possibilities In view, especially, of the utilisation of Britain's tropical resources, it is to be hoped that its investigation will not be left to America, but, on a conservative estimate, twenty times the number of scientific workers are engaged in the study of plant genetics in the United States compared with the number of workers in this field in the British Empire

Obituary

Mr E T Newton, F R S

EDWIN TULLEY NEWTON, who died in London on Jan 28, aged nearly ninety, was for many years a leader in the study of fossils in Great Britain He was born in London in May 1840, and at an early age was apprenticed to a handicraft which gave him special skill in designing and carrying out delicate manipulations He was at the same time deeply interested in natural history, and was fortunate in attracting the notice of Huxley, whose lectures he attended at the Royal School of Mines in Jermyn Street Eventually, in 1865, he became assistant to Huxley, who was then naturalist to the Geological Survey, and henceforth he was able to follow his inclination and devote himself to the study of life, both recent and fossil His official work, however, led to his dealing chiefly with fossils, and in 1882, when Mr Robert Etheridge left for the British Museum, he was appointed palæontologist to the Geological Survey, a position which he occupied until his retirement under the age limit in 1905

Newton's earliest noteworthy success, arising out of his routine duties, was the preparation of the first satisfactory microscope sections of coal, for use by Huxley in a lecture which he delivered at Leeds in 1870, and afterwards published in the *Contemporary Review* These sections aroused much interest, because they revealed masses of spores as the chief constituent of certain bituminous coals, and Newton followed up the subject in his first scientific paper, which was published in the *Geological Magazine* in 1875 Next he turned to the difficult task of preparing a regular series of transverse sections through the brain of a cockroach, which he described, with the aid of his own drawings, in the *Quarterly Journal of Microscopical Science* in 1879 Each of these sections represented a known thickness, and Newton reproduced them exactly on an enlarged scale in a series of plates of soft pinewood He then fixed the wooden plates together in regular order, and thus made a magnified model of the cockroach brain, which he described in the *Journal of the Quekett Microscopical Club* This was one of the first attempts to make a model from serial sections, and it is now preserved in the Museum of the Royal College of Surgeons

Newton's chief official duty as palæontologist to the Geological Survey, like that of his colleague George Sharman, was the preparation of lists of fossils for the memoirs which accompanied the maps Throughout his career, however, he did much more than official routine, and found both time and opportunity to make many important contributions to our knowledge, especially of the fossil Vertebrata His earliest researches of this kind were devoted to the Cretaceous fishes, and he published his results not only in short papers, but also in his well known memoir on the "Cretaceous Chimæroid Fishes", issued by the Geological Survey in 1878, and in the second edition of Dixon's "Geology and Fossils of Sussex", which appeared in the same year

Most of the English Cretaceous fish-remains were fragmentary, and Newton was always fascinated by fragments, which needed special skill and patience for their interpretation He was particularly interested in the scattered remains of the small mammals, birds, and fishes found in the later geological formations, and as the museums of London proved to be deficient in the skeletons of common existing animals which he wanted for comparison, he proceeded to make his own collection He thus brought together a valuable series of exquisitely prepared skeletons, which included parts often neglected, such as the otoliths of fishes Aided by this collection, he made great additions to our knowledge of the vertebrate fauna of Britain which immediately preceded the present, and his services were frequently sought when isolated bones and

teeth were discovered in cave deposits and other comparatively recent geological formations In this connexion may be specially mentioned his Survey memoirs on "The Vertebrata of the Forest Bed Series of Norfolk and Suffolk" (1882) and "The Vertebrata of the Pliocene Deposits of Britain" (1891), also his paper on the Pleistocene vertebrates from the Ightham fissure in Kent contributed to the Geological Society's *Journal* in 1894 He continued such researches at intervals until quite recently, his last paper, on a bone of a pelican from the Yorkshire peat, appearing in *The Naturalist* of June 1928 It may be added that Newton rarely dealt with controversial matters, but his account of a human skull found in a Pleistocene deposit at Galley Hill, Kent, published by the Geological Society in 1895, began a long discussion which still continues

Of all Newton's contributions to vertebrate palæontology, however, the most fundamental were three memoirs on fossil reptiles published in the *Philosophical Transactions* of the Royal Society In 1887, by the delicate preparation of the skull of a pterodactyl from the Upper Lias of Whitby, he gave the first satisfactory description of the brain of a flying reptile In 1893 and 1894, by taking gutta percha casts from the hollows left by the decay of bones which were once buried in the Permo Triassic sandstones of Elgin, Scotland, he utilised in an astonishing manner a most unpromising collection of the remains of various land reptiles, and revealed several skulls and other parts of the skeleton of genera closely related to some previously found only in the Karroo formation of South Africa and in corresponding rocks in India

Although occupied so much with research, Newton still found time to take an active part in the work of scientific societies in London For several periods he was a member of council of the Geological and Palæontographical Societies and of the Geologists' Association He was also a member of the publication and finance committees of the Zoological Society He was president of the Geologists' Association in 1896–98, and president of the Palæontographical Society from 1921 to 1928 He was elected a fellow of the Royal Society in 1893, and received the Lyell Medal from the Geological Society in the same year To his scientific worth was added a charming personality, unassuming and kindly, which leaves happy memories with all who had the good fortune to be associated with him

A S W

SIR GEORGE DANCER THANE

SIR GEORGE THANE died on Jan 14 within four months of the eightieth anniversary of his birth He was associated with University College, London, as student, demonstrator, professor of anatomy, and emeritus professor for more than sixty three years When only twenty years of age, and not yet qualified to practise medicine, he was chosen by Prof George Viner Ellis for the office of demonstrator of anatomy, and seven years later, on Ellis's retirement, Thane was appointed to succeed him in the professorship, which he occupied for forty two years

The mere enumeration of the forty nine years which Thane devoted to the teaching of anatomy at University College represents only one aspect of the great services he rendered Nor did the work or research in, and teaching of, anatomy form the major element in his whole hearted devotion to University College and to anatomy His greatest achievement was his cultivation of a personal knowledge of the students who worked under him, and of a sincere interest in their welfare, which he maintained throughout their subsequent careers He became their lifelong friend Thus his genial personality, and in particular his passion for accuracy in observation and restraint in expressing what he saw, influenced the lives of thousands of medical men and women This played a large part in building up the solid reputation of medical education in London

Thane had a very wide and exact knowledge of anatomical literature Among his contemporaries he was personally acquainted not merely with their published works but also with the men themselves in their laboratories and their social life By his own investigations he acquired the critical instrument for assessing the value of other anatomists' work, and his judgment and power of lucid expression made his own writings a sober and wonderfully accurate picture of the state of anatomical knowledge

Like his predecessors in the chair of anatomy at University College—the men who created "Quain's Anatomy" and made it the standard text book which was adopted as a model throughout the world—he put his best work into this book, rather than into the scientific journals His contributions to the 9th and 10th editions of "Quain's Anatomy" not merely maintained the high qualities and reputation of the work, but also extended its range and precision, and made it the most reliable and adequate text book on the subject that at the time had been produced

Thane was one of the founders of the Anatomical Society of Great Britain and Ireland, and years afterward when he became its president the respect in which he was held abroad was shown by an exceptionally large attendance of distinguished foreign anatomists Thane was an active member of the German and French anatomical societies, and took a delight in attending their meetings, as well as the international anatomical congresses

During his years of service as inspector of experiments on living animals, Thane took a keen interest in acquiring a personal knowledge of physiologists and in facilitating their work He was an honorary D Sc of Dublin and LL D of Edinburgh, and on his retirement from the active work of his professorship a knighthood was conferred upon him in recognition of his public service By his death his former students have lost a wise and kindly friend and the science of anatomy a teacher who unobtrusively did a vast amount of work to establish the foundations of an exact knowledge of the human body

News and Views.

DR. CARL STØRMER, professor of pure mathematics in the University of Oslo, Norway, is shortly visiting Great Britain—for the first time—primarily at the invitation of the University of London. He is known in scientific circles throughout the world as the leading authority on the aurora polaris. His work on this subject has covered a very wide range. On the side of theory he has developed mathematically the ideas first propounded by Kron Birkeland as a result of laboratory experiments on the projection of cathode rays towards a magnetised sphere representing the earth. In a long series of mathematical papers, Størmer has investigated the trajectories of electric corpuscles projected from the sun towards the earth and deflected by the earth's magnetic field; he has shown that numerous observed features of the aurora can thus receive a natural explanation. Many problems connected with auroræ and the associated phenomena of magnetic storms still remain unsolved, but it seems certain that much of Størmer's work will form an integral part of the complete theory when this is arrived at finally.

FURTHER, Størmer is a great pioneer observer of auroræ; he was the first to develop a practical and accurate method of determining the height and situation of auroræ in the atmosphere. Simultaneous photographs of the auroræ are taken, from two or more places connected by telephone, and on plates that also show some of the background of stars, which serve as reference points for direction. The telephonic facilities which he receives in this work from the national authorities in Norway, when an aurora is in progress, afford a remarkable instance of State co-operation in purely scientific research. Among his most important recent discoveries is the fact that the exceptionally high auroral rays, rising to heights of 700 km. or 800 km., are situated in the sunlit atmosphere, though they are viewed after sunset at the place of observation; he has also recently directed attention to the long period radio echoes, which he attributes to reflection by streams of solar corpuscles far from the earth. Prof. Størmer is lecturing in London on Feb. 28, Mar. 5 and 7, mainly on the theory of the aurora, but also on his observations, which he will illustrate with many of his beautiful auroral photographs. He is also visiting the Universities of Oxford, Cambridge, Manchester, Edinburgh, and Aberdeen. It is to be hoped that his visit, particularly to Scotland, will arouse new interest in the observation of auroræ by skilled amateur observers; an international committee, of which he is chairman, has prepared an auroral atlas, and various alternative plans, for use in such observations.

THE British Industries Fair, 1930, was opened on Feb. 17, and will remain open until Feb. 28. The London section is being held this year at Olympia instead of, as formerly, at the White City. The Birmingham section is held, as before, at Castle Bromwich. At London the exhibits cover a wide and diversified range of British manufacture, including—to take only a few examples at random—cutlery, jewellery, glassware, paper, leather, toys, scientific and optical instruments, wireless apparatus, musical instruments, chemicals, and textiles. The exhibits at Birmingham may be described as heavier, since they relate mainly to the iron and metal trades, power (lighting, heating, cooking, and ventilating plant), engineering, railway plant, mining plant, and brewing. While the London section is organised by the Department of Overseas Trade, the Birmingham section is organised by the Chamber of Commerce under the auspices and with the support of the Department of Overseas Trade. It should be noticed that only British manufacturing firms are permitted to exhibit, and that no exhibitor may exhibit articles other than those of his own manufacture. Since the Fair is organised for business and not for show, trade buyers are admitted to the Fair free between 10 A.M. and 8 P.M. on each day. The public are, however, admitted daily on payment between 4 P.M. and 8 P.M., except on Saturday, Feb. 22, when the hours will be 1 P.M. to 8 P.M.

IN order to further the business purpose of the Fair, the Department of Overseas Trade has installed a special office in the Fair where visitors and exhibitors can obtain commercial information on such subjects as tariffs, transport, etc. In addition, there is in each section of the Fair an officer of the Department who is prepared to give information as to conditions in overseas markets, sources of supply, the appointment of suitable agents, and other matters relating to export trade. Besides these facilities the services of interpreters are available free of charge. The British Industries Fair has grown steadily from strength to strength. It is perhaps the one Exhibition which offers, above all others, the greatest opportunity of seeing the latest developments in British manufactures gathered together under one roof—or, rather, under two roofs, one in London and the other in Birmingham. The importance of the Fair at this critical period in the manufacturing industry of Great Britain can scarcely be exaggerated.

AN interesting experiment has been inaugurated in Lanarkshire this week as a result of which ten thousand school children are receiving three quarters of a pint of milk daily until July. The scheme is the most ambitious venture in the realms of physiological research ever attempted in Great Britain. Five thousand children are receiving a ration of raw milk, five thousand are receiving pasteurised milk, and ten thousand will be observed as control subjects. All are being weighed periodically, and elaborate data regarding increase in stature, progress in health, etc., will be compiled at the close of the experiment. The enormous number of children involved in the test will ensure that results will be of so general a character that physiologists will be able to justify the broadest conclusions from them. It is expected by leading Scottish agriculturists that the consumption of milk in Scotland will be greatly increased as a result of the

experiment At present the consumption per head in Scotland is one of the smallest in the world, and an increase would raise the standard of public health in the country

FROM the medical point of view, this experiment in Lanarkshire is equally interesting All milk used is Grade A, guaranteed from herds free from tuberculosis At present almost three thousand cases of tuberculosis are reported every year in Scotland, and if this scheme assists by showing to the people the benefits derived from using the best milk available, then it will to a great extent have justified itself All the arrangements are in the hands of the Lanarkshire Education Authority and its staff of doctors, nurses, and teachers No administrative charges will require to be met, and all the money will be available to provide the milk The cost of the scheme is in the neighbourhood of £9000, of which £5000 has been granted by the Empire Marketing Board and £2000 by the Distress in Mining Areas (Scotland) Fund The remaining £2000 will be provided from a source not yet known The experiment was inaugurated at a meeting in Hamilton Academy on Saturday last, when an address was given by Mr Thomas Johnston, Under Secretary of State for Scotland Several Lanarkshire Members of Parliament also took part, and representatives were present from the West of Scotland Agricultural College, the Hannah Dairy Research Institute, the Scottish Milk Agency, Ltd , and the Farmers' Union Nine hundred gallons of milk are being supplied daily by the Scottish Milk Agency, Ltd

THE composition of the new Economic Advisory Council was announced by the Prime Minister in the House of Commons on Feb 12 Fifteen non Ministerial members have been selected to serve in an advisory capacity, and of these, five represent what may be called the academic side, namely, Mr G D H Cole, Sir Daniel Hall, Sir William Hardy, Mr J M Keynes, and Mr R H Tawney Seven of the members have been drawn from industry and finance, including Sir Arthur Balfour (chairman of the Committee on Industry and Trade), Sir John Cadman, Mr Ernest Debenham, Sir Andrew Duncan, Sir Alfred Lewis, Sir William M'Lintock, and Sir Josiah Stamp Labour organisations are represented by Mr Ernest Bevin and Mr W M Citrine, while Mr W R Blair is representative of the co-operative movement The Ministerial members of the Council, as already announced in the Treasury Minute dated Jan 27, are the Prime Minister (chairman), the Chancellor of the Exchequer, the Lord Privy Seal, the President of the Board of Trade, and the Minister of Agriculture Other Ministers may from time to time be invited by the Prime Minister to participate in the deliberations of the Council, and it has been stated that a number of distinguished industrialists and economists have consented to assist on specific points A whole time staff has also been appointed, consisting of Mr Thomas Jones (secretary), Mr H D Henderson, Mr A F Hemming, Mr H V Hodson, and Mr Colin G Clark

THE appointment of the Economic Advisory Council has recently been the subject of correspondence in the columns of the *Times* In the issue dated Feb 13, 'Econax' pointed out that a vast amount of economic information is already provided by various Government Departments, such as the Board of Trade, the Ministry of Labour, the Ministry of Agriculture and Fisheries, and the Ministry of Transport On the establishment of the Board of Trade there is a chief economic adviser to H M Government who is able to draw upon all the resources of the Board Empire problems of an economic character are already covered by the Imperial Economic Committee, the Imperial Shipping Committee, and the Empire Marketing Board In view of this very exhaustive machinery for the collection of economic data and for advisory purposes, 'Econax' argued that the setting up of an Economic Advisory Council is an innovation which appears to merit more detailed examination by Parliament than it has hitherto received Commenting on this letter, the *Times* stressed the existence of a network of departmental and other bodies created for the very needs which an Economic Advisory Council appears to be designed to supply "Why should the Civil Research Committee or the Melchett Turner Conference be superseded as co ordinating bodies", or if they were not to be superseded, "How was the new Council to supplement their work"? In a reply to 'Econax', Sir William Beveridge claims that some body is necessary to co ordinate the various economic activities of different departments so that the economic life of the country may be seen as a whole by the Government, although he admits that only experience can show if the new machinery will accomplish this object

PROF JULIAN HUXLEY, speaking on the aims of school biology, in an address delivered on Feb 8 to the School Nature Study Union, urged the cultural value of the subject, and deprecated unnecessary technicality in the teaching He pointed out the wide applications of biological principles to purely human, political questions, such as population, eugenics, social and personal hygiene, and so on, and their consequent national importance, and submitted that this consideration justifies the employment of biology as a 'bridge' by which the humanities should be linked with natural science, the easiest bridge being afforded by the history of biology In the course of the address it was shown that many of the facts and principles of chemistry and physics, including mechanics, can be approached and elucidated from the biological side, to mention but a few examples, respiration naturally leads to the chemistry of combustion, nutrition and metabolism to sources, expenditure, and conservation of energy, and also to the theory of solution and osmosis, skeletal structures to the mechanics of levers In actual practice, however, the order of teaching is almost always reversed, the chemical and physical processes exhibited by living organisms being approached through previous study of inanimate objects In view of the fact that Nature study, chiefly of a biological kind, is usually the first stage in science teaching, it is more rational to expand on this foundation in every possible direction so as to embrace the other subjects as

the educational edifice is enlarged, rather than to create a gap, and start the second stage, where definite scientific principles are properly introduced, *de novo* and disconnected from its predecessor

FOR his presidential address to the Optical Society on Feb 13, Mr F Twyman took as his subject "Optics in Radio Transmission and Other Fresh Fields" Optics, which originally meant the science treating of light and the phenomena of vision, has, said Mr Twyman, by general consent come to include the phenomena of infra red and ultra violet radiation The time is now ripe for a further extension to include other radiations, such as those used in radio trans mission and the X rays Not only does the propaga tion of all these radiations follow the same laws, but also the manifestations of them which have become of interest in recent years are often of a nature long familiar to those dealing with optics Furthermore, some of the recent developments have resulted from the application of minds trained in optics to considera tion of these other radiations Illustrations include the polarisation and interference of radio waves, the latter phenomenon enabling the height of the Heavi side layer to be determined, while the use of the notions associated with the diffraction grating have resulted in novel suggestions for radio transmission The 'optical' phenomena of X rays include the forma tion of characteristic spectra of the elements by the use of a crystal in a manner closely analogous to that in which the well known optical spectra are produced by means of a diffraction grating The production of Aston's mass spectra, in which atoms of varying mass are distributed, and photographically register their position in a 'spectrogram', was also dealt with

IN a leading article in the *Engineer* for Feb 14, reference is made to the appointment of Sir Harold Hartley as vice president of the London, Midland and Scottish Railway Co (NATURE, Feb 8, p 213), and to the subject of scientific research on the railways An advisory council of eminent men of science is to be set up under the chairmanship of Sir Harold, and our contemporary asks, among other things, whether the investigations made are to be solely for the benefit of the L M and S R, or whether the results are to be made available for the other companies Collective experiment and collective testing have gone further than collective research, and the question is of greater moment now, as a committee is inquiring into the question of the Department of Scientific and In dustrial Research establishing a locomotive experi mental testing station There are many matters, both technical and economic, connected with the railways that will pay for careful inquiry, and one of the things to be guarded against is unnecessary over-lapping and duplication It is pointed out that the capital invested in the railways of Great Britain amounts to 1211 million pounds, the receipts to 218 millions a year, and the expenditure to 177 millions, and that no fewer than 700,000 persons are employed on them To emphasise the value of research, the *Engineer* recalls the figures given by Mr Garcke at a recent luncheon of the British Electrical and Allied Industries Research Association Research work on insulating oils, he said, has cost £8500 but is saving £100,000 a year, researches on the heating of buried cables has cost £18,500, but has saved the industry at least half a million and added something like four millions to the duration value of the cables

THE movement for establishing scientific and in-dustrial museums in important provincial centres is one worthy of support from all those who have it in their power to further such projects, and it is with interest we learn that the North East Coast Institu tion of Engineers and Shipbuilders is taking active measures for the founding of an engineering museum in Newcastle In a memorandum, the Council of the Institution has given its reasons for so doing and it has now requested the Lord Mayor of Newcastle on Tyne to appoint a fully representative committee for the purpose of establishing the proposed museum As the metropolis of one of the largest industrial districts in Great Britain, Newcastle has cause to be proud of its long list of distinguished shipbuilders and engineers, and with the assistance of the great firms in the district there should be no difficulty in immediately forming a nucleus for such an institution Stephenson, Hawthorn, Armstrong, Swan, Palmer, Tweddell, Noble, and Parsons are but a few of those who, during the past hundred years, have contributed to engineer ing progress, and their names are written large across the annals of the Tyne Stephenson's first locomotives conveyed coal to the river Stephenson's shop in Forth Street was the first locomotive factory in the world, the *John Bowes*, the forerunner of our ocean tramps, was launched on the Tyne, hydraulic cranes and hydraulic tools were introduced there by Arm strong and Tweddell, the turbo generator and the marine steam turbine were brought to perfection there, while in the Tyne built vessels the *Turbinia* and *Maure tania* the river gave birth to two of the most historic ships that ever floated

WHILE engineering and shipbuilding occupy a fore most place among the industries of the north of Eng land, that of coal mining is equally important and its history goes back to the thirteenth century The development of coal mining and transport would alone form an interesting section for an industrial museum But Newcastle is the home of many industries to which science has given birth, as it is also the cultural centre of Northumberland and Durham, which have a population of more than 2,000,000 The museum thus should be not only a place for the preservation of memorials of the past but also an institution with definite educational aims We may perhaps be per mitted to express the hope that the exhibits will be chosen with the greatest care, that each section will be made to illustrate in orderly sequence the out standing improvements of the subject and that it will be borne in mind that a few objects well displayed are generally of greater use to the visitor than more extensive collections It should also be possible, in such a museum, to secure for temporary loan, collec-tions of a similar character to those distributed to local museums by the Victoria and Albert Museum,

and an essential part of the work of the museum should be the provision of occasional lectures both of an elementary character suitable for school classes and of a most advanced nature for the general public. In the development of a local technological museum such as is evidently contemplated, the committee will have many problems to solve; in the museums in London, Munich, and elsewhere, the committee will have much experience to draw on, but it will have at the same time the opportunity of founding a museum which might well become a model for others elsewhere.

The interest of Ur seems inexhaustible. Each report from Mr. Woolley now seems to open up fresh vistas in the development of the early civilisation of Mesopotamia. In the present season, the work of the month of December, which is described in the *Times* of Feb. 11, has revealed material which once more takes the time series back to a date far beyond the hopes of the excavator in this area a few years ago. Continuing excavation in the cemetery area, the expedition, among other discoveries, has found a man's burial with the remains of a wig decorated with gold ear rings and a gold frontlet, thus confirming a suspicion that the Sumerian nobleman was clean shaven and wore a wig on state occasions. The chief interest of the excavation in this area has now, however, been diverted to the huge rubbish mounds in which the graves were dug. Here eight well defined strata have been found. Over the graves is the stratum of the First Dynasty, about 3100 B.C.; below this a layer with slightly earlier seals; then a deep zone in which are nearly all the graves. Below the graves are five further layers containing tablets and seal impressions. It is interesting to notice that in the successive strata a gradual development from naturalism to convention in art is noticeable. Intricate linear designs such as are not known in any later period are sometimes combined with signs from the script. In some cases half the characters are new; in others they are interrupted by pictures, birds, bulls' heads, and the like, which suggest a transition stage between hieroglyphic and linear writing.

The whole series of new finds at Ur is unparalleled in Mesopotamia, so much so that it is suggested a foreign origin might be attributed if it were not for the clearly Sumerian character of other objects. Bulls' hoofs in copper exactly resemble the copper sculptures of the tombs, though more than 20 feet lower down. The stratification of the cemetery is to be closely related with that of the town site, where a second excavation is in progress. Here houses are found built one above the ruins of another. In a depth of 29 feet, eight separate buildings have been unearthed, the fourth of these from the top already older than the royal graves, and the sixth contemporary with the cemetery stratum which produced the bulls' feet and the remarkable seal impressions. In the eighth are splendid examples of the pottery painted in three colours hitherto reported only from Jemdet Nasr, near Kish, and below begin to appear the black and green sherds of the al 'Ubaid type. In this same stratum was found the figure of a wild boar in steatite, the oldest piece of sculpture from Ur.

A film phonograph which plays continuously for two hours has now been invented by Dr. C. W. Hewlett, the engineer to the General Electric Co. of America. A reel of film four hundred feet long but small enough to fit into a coat pocket can reproduce a complete play or opera which otherwise would require at least fifteen twelve-inch disc records. To obtain this result Dr. Hewlett utilises one of the methods used for recording sounds when making 'talkie' films. A jagged line photographed on the edge of the film represents the sound. Light coming from a narrow slit passes through the film into a photoelectric tube. As the teeth of the jagged lines pass by the slit the amount of light reaching the tube is varied and this varies the magnitude of the electric current. This current after amplification actuates a loud speaker and a clear reproduction of the original sound is made. According to the *Science News Letter* of Jan. 25, this 'child of the talkies' heralds the home entertainer of the future. The film has no sequence of photographs and contains only sound records. A continuous loop of film is used, unwinding from the inside as it winds up on the outside. With the present model, there is space for nine separate sound tracks, but this will doubtless be increased. When a track ends, the machine shifts automatically to the next in a fraction of a second, so that there is no practical interruption of the sound. The film runs at a speed of forty-five feet per minute, which is about half the speed at which ordinary talking motion picture films run. So far, no plans have been announced for the commercial development of the film phonograph.

Interest has been taken in Great Britain in gliding since 1896, when Pilcher and Weiss, to mention only two of the pioneers, made their successful experiments. In Germany, because the Peace Treaty made the use of aircraft difficult or impossible for the private owner, the glider was developed scientifically, with the result that an entirely new type of aircraft, the 'sail plane', was evolved. The glider will fly in a strong upward current of air such as is found on the slopes of hills, but it is not capable of extending the flight beyond the limits of this current of air. The 'sail plane', although it requires a moderate upward current of air to start its flight, is able to make use of the very slight upward trend of the air which supports cumulus clouds, the force of gusts of wind, and line squalls, as well as those very slight currents of air that are due to the changes in the reflection of the sun's rays by variations in the surface of the ground. The ability of the 'sail plane' to soar in the same manner as a bird opens fresh possibilities in the field of aeronautics. In Germany the Rhön Rossitten Gesellschaft, and in the United States the National Glider Association Inc., have drawn up regulations to ensure the adequate strength and safety of gliders and 'sail planes'. They issue certificates of airworthiness, approve gliding grounds, and license pilots and instructors for these engineless aircraft. In Great Britain the British Gliding Association, 44A Dover Street, London, W.1, will do the same work; full regulations will be announced at the inaugural

meeting to be held on Mar 27 Lord Wakefield is presenting a cup to the Association, which will be awarded for the most meritorious performance

AT the meeting of the Linnean Society of London on Feb 6, the president, Sir Sidney F Harmer, exhibited a pair of shoe laces, and commented on their zoological interest as illustrating a remarkable characteristic of the Delphinapteridæ This family, the only recent species of which are the white whale (*Delphinapterus leucas*) and the narwhal (*Monodon monoceros*), both Arctic animals, differs from other Cetacea in the structure of the skin The epidermis in this order is normally in immediate contact with the blubber, a thick layer of dermis containing a great quantity of oil or fat In the Delphinapteridæ the epidermis is separated from the blubber by a superficial layer of dermis, which by suitable treatment becomes leather of excellent quality, generally known as 'porpoise leather' The laces exhibited had more elasticity than ordinary leather, and probably were actual products of *D leucas*, as indicated by the designation, 'genuine white whale buckle laces', under which they are being sold The white whale has been captured in limited numbers, during recent years, chiefly by vessels operating from Norway

PROF B BLACKLOCK, of the Liverpool School of Tropical Medicine, delivered a Chadwick Public Lecture on Feb 13, taking as his subject "Health in West Africa" The health problems of the British West African colonies are of growing importance The increase of annual West African trade, from sixteen million pounds in 1907 to sixty million pounds in 1927, has resulted in a large influx of white residents The fall in the death and invaliding rate among Government officials since the beginning of the century has been remarkable For the period 1881–97, the Gold Coast officials had a death rate of more than 75 per 1000 per annum, and Nigerian officials a death-rate of more than 53 per 1000 per annum, for 1928 the death rate for officials over the whole of the West African colonies, including Gambia, Sierra Leone, the Gold Coast, and Nigeria, was only 6 7 per 1000 It would be useful to have similar figures from commercial firms with employees in West Africa The marked improvement in the health of Government officials reflects great credit on the medical and sanitary administration But it was obtained only by the co operation of the total white residents, the European in West African coastal regions can only keep free from disease by meticulous care of himself Even when free from actual sickness, the average European does not feel fit in the West African low lying country, better housing and more suitable recreation, in which the governments might take an official interest, will help to eliminate part of this disability Prof Blacklock then discussed the problem of trying to bring the housing, diet, and general sanitation of the native up to a reasonable standard In West Africa there are under British rule some 25 million natives, and the vast majority of them are remote from medical aid Good work has been done in Sierra Leone in the form of a survey of disease and the construction of good motor roads, but a very great deal can also be done by the education of the native, in his own tongue, in elementary hygiene

THE major contribution in the January number of the *Natural History Magazine* of the British Museum (Natural History) is Dr Rendle's popular account of some of the impressions made upon a botanist by his recent tour with the British Association in South Africa Many naturalists will read with interest also R I Pocock's unravelling of the identity of the 'Nandi bear', an unidentified predatory animal, held in horror by the natives of East Africa (according to themselves), which so far has eluded the white sportsman The skin and skull at last received as the authentic relics of this creature turn out to be, as regards the skin a spotted hyena, and as regards the skull a leopard The entire story of this fabulous beast and the solution prove again the need for the closest and most critical scrutiny of natural history information derived from native sources

THE Royal Air Force is to be congratulated on the distinct success achieved with the first issue of its new journal, the *Royal Air Force Quarterly* The magazine has for its object the promotion and advancement of aeronautics, both in and out of the service, and if the standard of future issues can be kept as high as that attained in the first, so far as quality at any rate is concerned, its success is assured The articles deal, among others, with such diverse questions as operations in the Near and Far East, co operation in the Army and Navy Air Force, air strategy, analysis of leadership, preparation for the Staff College, Trans Jordania, wind structure, metal military aircraft, and high speed flight—clearly a very broad field of view The journal is illustrated by a series of exquisitely produced and valuable photographs and reproductions which reflect great credit on the compilers It is to be hoped that an equally high standard of finish will be maintained in future issues

THE Medical Research Council has appointed Air Vice-Marshal David Munro, on his retirement, as Director of Medical Services, Royal Air Force, to be Secretary of the Industrial Health Research Board in succession to Mr D R Wilson, lately appointed Deputy Chief Inspector of Factories at the Home Office The appointment will take effect on Mar 1

THE following officers and new members of Council of the Royal Astronomical Society were elected at the annual general meeting of the Society on Feb 14 *President* Dr A C D Crommelin, *Treasurer* Mr J H Reynolds, *Secretaries* Prof H Dingle and Dr W M Smart, *Foreign Secretary* Prof H H Turner, *New Members of Council* Dr J A Carroll, Dr J Jackson, Mr B M Peek, and Prof F J M Stratton

SIR WILLIAM BRAGG, Fullerian professor of chemistry in the Royal Institution and director of the Davy Faraday Research Laboratory, has been awarded the Franklin Medal by the Board of Managers of the Franklin Institute, Philadelphia, "In recognition of a life work in the study of X-rays and radio-

activity, in the course of which he made fundamental contributions to that realm of physics, of his development of a method of determining molecular and crystal structure by the reflection of X rays and of his fruitful guidance of the Davy Faraday Research Laboratory and the Royal Institution of Great Britain "

THE High Voltage Research Laboratory of the Metropolitan Vickers Electrical Co, Ltd at Trafford Park, Manchester, will be opened by Sir Ernest Rutherford, President of the Royal Society, on Friday, Feb 28 In recent years the Company has been developing building accommodation, equipment, and staff at Trafford Park to deal satisfactorily with its requirements for investigational work in the whole field of high voltage phenomena The nature of the opening function on Feb 28 will be a short formal ceremony by Sir Ernest Rutherford, followed by some special demonstrations, and an inspection and examination of the detailed equipment in the high voltage laboratory itself, and also in the other laboratories of the Company, covering a wide field of physics, metallurgy, and electrotechnics generally

IN consequence of inquiries respecting psittacosis or parrot fever, the Ministry of Health has issued a memorandum on the subject which should prove useful to medical officers of health and others (Memo 151/Med London H M Stationery Office, price 1d) The characteristics of the disease and the circumstances of its occurrence are described and precautionary measures suggested, and should suspected cases occur the data of importance for investigation are detailed

A NEW (the third) edition of "Studies concerning the Handling of Milk" (*Research Monograph* No 1) has been issued by, and may be obtained from, the Ministry of Agriculture and Fisheries, Whitehall Place, S W 1 (1s net post free) It contains much valuable and detailed information on the factors concerned in the production of clean and wholesome milk

MESSRS W Dawson and Sons, Ltd, Cannon House, Pilgrim Street, E C 4, have just issued a catalogue (N S No 2) of scientific journals, transactions of learned societies, and books relating to travel, topography, ethnology, anthropology, statistics, etc The list is noteworthy for the many sets and long runs of scientific serials and transactions offered for sale—the longest to reach us recently It should be seen by all who wish to fill up gaps in their libraries

WITH the publication of the January number, the *Collection of Czechoslovak Chemical Communications* begins a second volume of this new journal The first volume (reference to articles in which have appeared in NATURE) contained 690 pages In the January number there are papers on adsorption phenomena at a mercury dropping electrode and on the preparation of new sugars in the series of methyl pentoses There is also a bibliography of Czechoslovak chemical publications which have appeared during 1929 in various journals

THE first number has reached us of the *Journal of Dairy Research*, a new periodical published on behalf of the Dairy Research Committee of the Empire Marketing Board and edited by its chairman, Prof Stenhouse Williams The journal is designed to include reviews by specialists of existing knowledge in different aspects of dairying, original contributions to dairy science, and reviews and abstracts of current literature, and is published by the Cambridge University Press in half yearly parts of about 100 pages at the subscription price of 15s per volume of two parts The present number contains a foreword by Lord Passfield, a review monograph by E T Halnan on feeding standards for dairy cows, four original articles, and abstracts and reviews of current literature

MONTHLY summaries of current scientific and technical literature dealing with water supplies, sewage, trade wastes, river pollution and relevant subjects have been prepared during the past two years by the Department of Scientific and Industrial Research These summaries were compiled primarily for the use of the Water Pollution Research Board of the Department, and a limited number of copies were circulated in neostyled form There is evidence that these summaries would be of value to a wider public, and it has been decided, therefore, to issue a monthly publication containing selected abstracts, the first number of which has just been issued as *Summary of Current Literature*, Vol 3, No 1, January 1930 Abstracts Nos 1 119 Water Pollution Research Department of Scientific and Industrial Research (London H M Stationery Office 1s 3d net Annual subs 15s net)

APPLICATIONS are invited for the following appointments, on or before the dates mentioned - A junior lecturer in mathematics at the Royal Military Academy, Woolwich —The Commandant, Royal Military Academy, Woolwich, S E 18 (Feb 28) A lecturer in charge, with good degree in physics and chemistry, and a lecturer in applied science, at the Abertillery Mining and Technical Institute—D Brynmor Morgan, County Hall, Newport, Mon (Feb 28) An assistant lecturer in metallurgy in the University of Birmingham—The Secretary, The University, Birmingham (Mar 3) An assistant lecturer and demonstrator in anatomy in the Faculty of Medicine of the University of Birmingham—The Secretary, The University, Birmingham (Mar 10) A keeper of the Natural History Division of the National Museum, Dublin, and two assistant keepers in the Art and Industrial Division, one assistant in the Irish Antiquities Division, and one assistant in the Natural History Division of the Museum—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin (Mar 10) A senior and a junior research assistant under the Animal Diseases Research Association — The Secretary, Animal Diseases Research Association, Moredun Institute, Gilmerton, Edinburgh (Mar 31) A temporary part time mathematics master at Willesden Polytechnic — The Principal, Willesden Polytechnic, Priory Park Road, Kilburn, N W 6

Research Items

Birth- and Death-rates—In an article by Dr C Tietze in the *Eugenics Review* for January last, interesting data regarding the birth and death rates in Germany are given, as well as comparable statistics for England and France Since 1925 the birth rate of England has been less than that of Germany or France England and Germany were nearly equal in 1920, at 25 5 and 25 8 respectively The French rate was then 21 3, but afterwards fell to 18 2 (1928), while Germany was 18 6 and England 16 7 But considering the number of child bearing women, the French birth rate is 10 per cent higher than the German All these diminishing rates are evidently due to wider use of contraceptives and increased abortions Death rates have similarly declined from 26 in Germany and 21 4 in England in the period 1841–45, to 11 6 and 11 7 respectively in 1928 The net reproduction rate is now below zero in western Europe, but of the three countries considered, it is lowest of all in England and highest in France Predicting from such figures, the population of both England and Germany will probably begin to decline in the period 1940–50

Boredom in Industry—Report No 56 of the Industrial Health Research Board is concerned with an investigation into the effects of monotony in work, by Wyatt, Fraser, and Stock Output curves from workers in several industrial processes of a repetitive kind were obtained and these were related to subjective experiences with regard to interest and boredom It is clear that there is considerable individual variation in susceptibility to boredom, although there were very few of the subjects who were seldom or never bored The more intelligent workers were more liable to boredom on repetitive work than the others The effect of boredom was to reduce the rate of work and to increase the variability Boredom was also related to the degree of mechanisation, it was less likely to occur when, (*a*) the work was entirely automatic so that the thoughts could wander to other things, or (*b*) when attention could be entirely concentrated on the work The effects of different methods of remuneration, whether piece rates or time rates, the influence of the group and other complicating factors are also considered The report is described as of a preliminary nature, but the problems raised are so important for industry that it is well that they should be formulated and studied scientifically

Breeding Grounds of Blue Goose—Although the blue goose (*Chen cœrulescens*) is a migrant which is familiar in winter in the United States, where it then inhabits the estuary of the Mississippi River, until now its breeding ground in the Arctic has never been found A great search for this mysterious summer haunt, which was generally thought to be in the northern regions of Canada, has finally been crowned with success The discoverer, J Dewey Soper, in his long drawn out exploration, spent nearly three years in the task and covered about 30,300 miles in all, of which 4000 miles were by dog team and small boat in and about Baffin Island (*Canadian Field Naturalist*, January, p 1, 1930) In June the birds began to enter the breeding area, by June 8 and 9 thousands appeared, but the heaviest influx, which included, besides snow geese and blue geese, also brent and Hutchin's geese, occurred in the middle of the month Even then the nesting ground was difficult to locate, but on June 26 a group of ten nests, eight of them those of blue geese, was found on the tundra near Foxe basin in latitude 65° 30′ N An account is given of the nest and the characters which distinguish the downy young of the blue and lesser snow geese

Growth in Insects—The observations upon the growth and development of some ten species of dragonflies (Odonata), made by Philip P Calvert, have some interesting general results (*Proc Amer Phil Soc*, vol 68, p 227, 1929) The number of moults was found to vary, and therefore moults are not absolute indicators of biological age Nor do they show that rigidity of growth which has been expressed by the Brooke Przibram ratio of 1 25 or 1 26 Ten species of dragonflies were reared from egg to adult, and the ratio of each instar recorded Nine of the species gave a more rapid rate of growth than the ratio demanded, and the ratios from instar to instar were very inconstant The growth factor varies in an irregular way from instar to instar in dragonfly larvæ and in other arthropods, and these variations are not correlated with changes in the character of the food, facts which detract from the value of Brody's comparison of growth in warm blooded and cold blooded animals Adults of insects with complete metamorphosis are usually smaller than their corresponding larval stages, a character exhibited by a few non arthropods But in the great majority of non insectan animals the relationship resembles that in insects with incomplete metamorphosis, where the adults usually exceed in length the larvæ from which they have developed

Arctic Diatoms—Dr D Vito Zanon, S C, in a paper entitled "Diatomee della Baia del Re (Swalbard)" (*Memorie della Pont Accademia delle Scienze Nuovi Lincei*, Serie 2, Volume 12, 1929), describes a number of diatoms from King's Bay on the west coast of Spitsbergen These were collected by Dr P Gianfranceshi during the polar expedition undertaken by General Nobile, and consist mainly of littoral and bottom forms, although a few planktonic species are recorded A full list of arctic diatoms is given and a large number of these were found in the material investigated, besides other forms which are new for that region, several new varieties and one new species, *Denticula nobilei*, which is named after General Nobile Among the planktonic species are *Rhizosolenia hebetata* and four species of *Chœtoceros* which are new Spitsbergen records

Striated Muscle in Liver of Spider—S Maziarski (*Bull Internat Acad Polonaise Sci*, Series B, No 3, 6BII, 1929) describes the occurrence in the liver of spiders (*Tegenaria*, *Araneus*, *Epeira*) of numerous contractile elements in the form of branched transversely striated muscle cells These are disposed on the external face of the basal membrane of the acini of the gland and form a network either by intercrossing or by direct anastomosis of the prolongations of the cells In their form and position these cells correspond with the branched cells which have long been known—under the name of the basket of Boll—in the salivary glands of vertebrates In the latter the branched cells are smooth and are situated on the internal face of the basement membrane The presence in the liver of spiders of cells the muscular nature of which is beyond doubt, homologous with those in the salivary glands of vertebrates, confirms the view that the basket of Boll is contractile The liver of spiders is a diverticulum of the intestine and its glandular follicles, richly branched and anastomosed, open by four or five ducts into the gut The considerable development of

muscular tissue in the liver is, in the author's view, correlated with the double function of this organ. The follicles are lined with two kinds of cells; some are glandular and produce digestive ferments and the other cells absorb the digested material. The muscular tissue is responsible for the transport of material from follicle to follicle.

Wild Cacao.—Two interesting photographs by Prof. G. Stahel, director of the Surinam Agricultural Experiment Station are reproduced in *Kew Bulletin*, No. 1, 1930, which show what is thought to be indigenous, wild cacao growing along the valley of the Mamaboen Kreek, where it is many miles away from any original plantations or even from any Indian village. The plants in this valley were extraordinarily uniform in character and could definitely be identified as belonging to the type *Forastero*. Another point of great interest which has been observed by Prof. Stahel is that on this natural growth of cacao can be found the witch's broom disease, *Marasmius perniciosus*. This disease, which is only known upon cacao, has of recent years made very serious inroads upon the Surinam plantations, which are some 175 kilometres distant from the valley where the native trees grow, on which the disease occurs to a very large extent. The *Kew Bulletin* contains an account by Dr. J. G. Myers of his visit to this locality for native cacao on behalf of the Empire Marketing Board. Dr. Myers had in view the possibility of the biological control of the more important insect pests of cacao in the West Indies. However, the chief insect pests of cacao were not found attacking the wild tree, which seems to suggest that thrips and the cacao beetle have become attracted to cacao, from other wild host plants, since it has come under extensive cultivation.

Soil Science in Sweden.—The recent appearance of the second number of vol. 3 of *Forestry*, the journal of the Society of Foresters of Great Britain, shows that the high level efficiency of the publication is maintained. An interesting paper in this issue is 'Forest Soil Science in Sweden', by G. V. Jacks. Mr. Jacks' paper discusses the position to which the researches in soil science have reached in Sweden since the first serious inquiries were undertaken and the foundations laid by the work of Sveriges Geologiska Undersökning in the middle of last century. Since the beginning of the present century the work has proceeded under the auspices of the Statens Skogsforsöksanstalt, an institute under State control. Prof. Hesselman, who was responsible for assembling the International Congress of Forest Research Stations which met at Stockholm in July last (a description of the proceedings of which is also given in the present issue), is the president and is assisted by Dr. O. Tamm, geologist, and Dr. C. Malmström, botanist. The soil investigations have been mainly carried out with a practical, usually forestry, end in view, but they have involved a great deal of research of a purely scientific value. Mr. Jacks' paper is therefore well worth consideration on both counts.

Rust Recurrence on Indian Wheat.—This subject formed the theme of Prof. K. C. Mehta's presidential address to the Botanical Section of the Indian Science Congress (*Proc. Sixteenth Indian Sci. Congr.*, Madras, 1929), in which he gave a very clear account of the interesting conclusions that follow from his own work upon this subject. It would appear that on the plains, rusts on wheat are only found over a period of three months in each year; the uredospores are then killed by the summer heat and no source of rust infection is left upon the field when the new crop is sown. With each species of wheat rust investigated, the source of reinfection appears to be in the hill country, where the uredospores survive through the critical summer period on self sown plants and tillers. Prof. Mehta's earlier experience upon the overwintering of rusts in England, when working with Mr. F. T. Brooks at Cambridge, may have helped him in reaching this conclusion; his case is stated temperately and clearly and seems to be based upon long and careful observation, involving considerable travelling. Prof. Mehta complains that the progress of this important investigation has been delayed by lack of financial support. This would seem surprising in the case of such an important practical problem. His results suggest that, with financial support, it might be possible to attempt some control of rust dissemination on wheat by attempting the eradication of the rust hosts in some of the hill localities, or controlling more carefully the growth of wheat in regions where the rust is able to overwinter.

Irrigation in India.—Some interesting figures appear in the review for 1927–28 of irrigation in India, published by the Department of Industries and Labour of the Government of India. The monsoon broke about the usual time and its progress was normal, but there was a slight deficiency of rain in many of the plain areas. The total area irrigated in British India by government works of all classes was twenty seven and a half million acres, which amounted to 11.5 per cent of the total area sown. In Sind, the irrigated area was 76.8 per cent of the total area; in the Punjab 35.2 per cent; and in the Madras Presidency 18.6 per cent. In most of the provinces further irrigation works are in progress. Details are given of these and of projects under consideration. One of the most important schemes in hand is the Sukkur barrage on the Indus. Important works are also on hand in the North-West Frontier Province, where drainage works are being constructed to relieve the waterlogged soil of the irrigated areas. This has already resulted in heavier crops and the recultivation of many acres which for long have been lying waste.

Multiple Origin of the Japanese Earthquake of 1923.—Two papers have recently been published on the multiple origin of this earthquake. Prof. A. Imamura (*Tokyo Imp. Acad. Proc.*, vol. 5, pp. 330-33; 1929) shows that the initial portion of the seismogram at Tokyo contains three distinct phases due to movements from different centres. The first came from an origin in Sagami Bay to the north of the island of Oshima, the second 3 seconds later and much stronger from one near Mount Tanzawa, about 18 miles to the north-north-west, and the third and greatest of all, after $4\frac{1}{2}$ seconds more, from a centre about half-way between. Prof. Imamura remarks that the varying directions of the initial motion are explained by the existence of these different centres. He also shows, from a study of the measured changes of level, that faults with noticeable scarps are continued for some miles either as faults or flexures, some of them more than 12 miles in length. Prof. Koto (*Jour. Fac. Sci.*, *Tokyo Imp. Univ.*, vol. 3, pp. 1-21; 1929) refers to the existence of a contributory seismic zone about nine miles to the north of Tokyo along the valley of the old river Ara-kawa. After the earthquake of 1894, he traced a fault track 18 miles in length along this valley, and, after the earthquake of 1923, he mapped a broad destructive area along the same zone.

Geological Structure of New Zealand.—A most valuable paper to students of tectonic geology in general and of New Zealand in particular is contributed by Dr. J. Henderson to the *N.Z. Jour. Sci.*

and Tech, vol 11, Aug 1929 It is illustrated by a map showing the main structural lines, depressions, and lowlands of the islands, and by two large scale maps (prepared by the late Mr P G Morgan), which are not issued with the *Journal* but can be obtained by subscribers from the editor New Zealand is regarded as the shattered crest of two crustal up bowings that meet at right angles in the Taupo region, the earth stresses involved having been active during the late Tertiary Theoretically, the shear zone due to horizontal pressure in the crust should curve upwards from a horizontal sole, reaching the surface as a fracture curved in plan and dipping steeply The block rises vertically in front and rotates on the curved surface on which it rests The original upper surface of the block thus comes to be tilted away from the inner side of the fault trace Many of the faults and blocks of New Zealand show features in close agreement with theory There is good evidence for the following statements (1) The mountain building faults, wherever observed, dip steeply (2) Many of the faults are arcuate in plan (3) Many blocks are back tilted from the bordering fault (4) Many blocks are highest near the central part of the fault (5) Several faults grade into anticlines The north east trending crustal ridge of which New Zealand is the highest part may be considered as the upthrust edge of a gigantic earth block with its frontal scarp overlooking the Tonga Deep Pressure at right angles has raised on this block a number of isolated north west trending ridges, of which the Auckland Peninsula and New Caledonia are ex amples

Elastic and Electric Properties under Pressure —The December issue of the *Proceedings of the American Academy of Arts and Sciences* contains two papers by Prof P W Bridgman of Harvard which continue his long series on the properties of substances under hydrostatic pressures of the order of 12,000 atmo spheres The first shows that, in general, pressure increases the modulus of rigidity of a metal less than 6 per cent per 10,000 atmospheres, and in the case of two rare metals diminishes it slightly In the second, the compressibilities of four single crystals of metals, seven of inorganic and four of organic substances, and lastly of bakelite, are determined The diminution of 1 cm parallel to an axis of a crystal due to a hydro static pressure of 12,000 atmospheres is of the order 1 to 6×10^{-4} cm and varies almost as much from one axis to another in the same crystal, particularly in inorganic crystals The electrical resistances of indium, manganese, chromium, and arsenic all de crease with increase of pressure and are thus normal, while arsenic appears to undergo a modification of form at 5500 atmospheres

Properties of Ammonia —The thermodynamic properties of ammonia are of considerable importance in connexion with its use in refrigeration In the January number of the *Journal of the American Chemical Society*, Beattie and Lawrence deal with these properties and describe experiments on the com pressibility of gaseous ammonia and the vapour pressures of liquid ammonia from 30° to 132° An equation of state for the gas is derived from the first set of experiments, the vapour pressures are in agreement with those found by the U S Bureau of Standards and by Keyes and Brownlee

Combustion of Charcoal —The nature of the chemical reactions involved in the combustion of charcoal has long been a matter of investigation and dispute The theory usually accepted at present is that put forward by Rhead and Wheeler in 1912 on the basis of experiments, namely, that the oxygen is first attached to the carbon in the form of a loosely formed complex, C_xO_y, which at higher temperatures decomposes into carbon monoxide and dioxide The view that the oxygen is adsorbed is also tenable, especially since Langmuir has identified the forces holding adsorbed molecules on surfaces as primary or residual valency forces of the atoms composing the surface The fact that the adsorbed oxygen cannot be removed as such by reducing the pressure, and appears to be firmly bound, is better explained by Rhead and Wheeler's theory, although Richardson in 1917 could find no evidence of a complex oxide in the study of the reverse action of carbon dioxide on char coal at relatively high pressures In the December number of the *Journal of the Chemical Society*, M S Shah describes experiments on the combustion of charcoal in oxygen, nitrous oxide, and nitric oxide It is well known that brightly burning charcoal burns more brilliantly in nitrous oxide than in air, but does not continue to burn in nitric oxide, although the latter contains more oxygen He considers this anomalous, although it is usually explained by the undoubtedly greater thermal stability of nitric oxide The main result of the work is that the initial stage in all three cases seems to be due to fixation of oxygen Charcoal retains nitric oxide as well as oxygen, re action then proceeds between the charcoal and the fixed gases, and the ultimate products are carbon dioxide and nitrogen Even in a rapid stream of gas no carbon monoxide was detected, whilst with oxygen and nitrous oxide both monoxide and dioxide were formed Shah prefers Langmuir's adsorption theory to the chemical complex theory of Rhead and Wheeler, and shows how, when suitably modified, it is capable of explaining his results

Power Measurement in an Alternating Current Circuit —One of the most difficult problems which electrical engineers have to solve is the measurement of the power in an alternating current circuit The measurement of direct current power is easy, one has merely to measure the current and the pressure and multiply them together This can be done by a single instrument called a wattmeter, which can be calibrated with a maximum inaccuracy of about the tenth of one per cent Wattmeters suitable for measuring alter nating power at high voltage when the current is large are much more difficult to construct In calibrating the instrument, not only have the current and the voltage to be measured but also the difference of phase between them The mean power is the product of the voltage and the current into the cosine of the phase difference As transformers have to be used to reduce the pressure and voltage to values which can be measured by voltmeters and ammeters, the trans forming ratios of these devices have to be very accur ately determined As the power to be measured is far larger than any available in a testing laboratory, artificial 'loads' for the meters have to be made up, the voltage coil being actuated by one circuit and the ampere coil being actuated by another, the circuits being arranged so that the phase difference between the currents flowing in them can be accurately calcu lated At the Institution of Electrical Engineers on Feb 7, three papers dealing with this problem were read The first paper, by G F Shotter, described a null method of testing instrument transformers The second paper, by R S J Spilsbury and Dr Arnold of the National Physical Laboratory, described the accessory apparatus required for the precise measure ment of large currents In the third paper Dr Arnold described a rapid and accurate method of testing current transformers by means of a potential divider bridge

History of Medicine.

TWO interesting lectures connected with the history of medicine were delivered at the Wellcome Medical Historical Museum at the end of last month by Sir William Willcox and Dr A P Cawadias respectively The former, who chose the subject of secret poisoning for his address, stated that the recent excavations in Mesopotamia have shown that an interest in poisons could be traced back to about 4500 B C, when a goddess named Gula was worshipped by the Sumerians under the name of The Mistress of Charms and Spells and Controller of Noxious Poisons The first scientific student of poisons, however, appears to have been Mithridates king of Pontus, who not only conducted toxicological experiments on condemned criminals and others, but also wrote a book on the subject and invented a universal antidote which according to Celsus, consisted of thirty six ingredients It is recorded that when he wished to commit suicide by poison, rather than surrender to the Roman invader, his constitution had become so inured to various poisons that his attempt was unsuccessful and he had to ask a mercenary to dispatch him with a sword His name survives in modern scientific nomenclature, in the term 'mithridatism', which signifies immunity to poisons, bacterial and otherwise, acquired by gradually increasing doses of the poison itself

During the Roman Empire, Agrippina and her son Nero made elaborate studies in experimental toxicology on the human subject, and by the knowledge thus obtained successfully removed the persons who incurred their disfavour In the course of the next thousand years, poisoning was extensively practised without, however, any great developments taking place in the science of toxicology, and it was not until the time of the Italian Renaissance that an intensive study of poisons was made, the most notorious experts in this field being Pope Alexander VI and his son Cæsar Borgia

Until modern times, the methods of detection of poisons depended mainly on the circumstances attending their administration Nothing was really known about the post mortem appearances, and toxicology did not make any great advance until the development of modern chemistry and its application to the analytical problems with which toxicology is concerned While the only certain sign of poisoning is the identification by analysis of the poison in the body, of recent years so much progress has been made in morbid anatomy and histology that the post mortem appearances often indicate the poison responsible for death apart from its detection in the body by chemical analysis In conclusion, Sir William Willcox illustrated his address by the exhibition of curious poisons and their antidotes from the museum

Dr Cawadias, whose address was entitled "From Epidaurus to Galen The Principal Currents of Greek Medical Thought", maintained that rational medicine was invented by the Greeks and that before their time the general attitude towards disease was irrational, medicine being essentially religious and magical in character Although faith healing was an important feature in the cult of Æsculapius at Epidaurus, it was limited to special cases of non organic disease, and was free from the mystic element of the religious medicine of the ancient peoples of the East Every period of ancient Greek medicine, of which five can be distinguished, is based on the physiological work of the ancient Ionian natural philosophers such as Thales and Anaximander

In the first period, which included the seventh, sixth, and early fifth centuries B C, a method of diagnosis based on physiological considerations with very elementary clinical control was elaborated together with rules for diet and gymnastics In the second period, which included the fifth and fourth centuries B C, Greek medicine became based on more precise physiological knowledge gained mainly by the researches of Anaxagoras of Clazomenæ, Democritus of Abdera, and Diogenes of Apollonia The general mechanism of disease was explained more precisely by the doctrines of Hippocrates Clinical medicine reached its zenith through the method of nosographical diagnosis developed by the Cnidians as well as by the method of personal diagnosis devised by Hippocrates and the school of Cos

The doctrines of the third period, which included the last three centuries B C and the first two centuries A D, were based on the physiological works of Aristotle and marked a very great advance in the knowledge of the functions of the various organs This physiological work was supplemented by the Alexandrian physicians Herophilus and Erasistratus Numerous medical schools flourished during this period While the Alexandrians of the third century B C controlled research in physiology by a strict clinical examination, the Methodists and Pneumatists made physiology the sole basis of diagnosis and neglected the clinical method The Empirics, on the other hand, confined themselves to clinical considerations and refused to consider any diagnostic method connected with the physiological mechanism of disease

The fourth period of Greek medicine is represented by Galen alone (A D 130–200), whose physiological work marked an enormous advance on that of Aristotle owing to the introduction of the experimental method The fifth and last phase of Greek medicine was a period of compilation and transmission, the principal compilers being Cælius Aurelianus (A D 400), Oribasius (A D 326–403), Alexander of Tralles (A D 525–605), and Paulus of Ægina (A D 600–650) Their compilations were used by the Nestorian monks, who transmitted Greek medicine in the sixth and seventh centuries to the Arabians and through them in a slight degree to western Europe The transmission of Greek medicine, however, was mainly due to the Greek scholars of the fifteenth century, who had left Greece after its conquest by the Turks

Cotton in Africa

THE report of the executive committee of the Empire Cotton Growing Corporation to the meeting of the administrative council, held in Manchester on Jan 21 last, contains several important scientific observations on the growth of cotton in Africa

The diseases and pests which attack the cotton plant are many, and each locality has its particular problems to solve in breeding resistant strains Cotton growing in South Africa has suffered from attacks by the jassid insect, and it is interesting to note that a strain has been isolated which is resistant to this pest The new strain of cotton is giving high yields, which is of primary importance to the grower, and recent experience has shown that it is capable of giving good crops in districts with a seasonal rainfall of 10 inches, whereas it is generally considered that a minimum of 20 inches is necessary for cotton

growing In Uganda, one of the most promising cotton growing regions in South Africa, there are good prospects of increased yields, and steps are being taken to ensure this by instructing the native growers in improved methods of cultivation, and by effectively controlling the seed supply

The cottons which the Corporation is cultivating in South Africa are of the American type, and are intended to provide the Empire with sources of supply other than America It is to the Anglo Egyptian Sudan that we have to look for the supply of the better quality cottons of the Egyptian type The Sudan is now producing an increasing quantity of cotton which is almost indistinguishable from the best qualities of long staple Egyptian cotton Recently the disease known as leaf curl has been attacking the crops in this locality, and there is evidence that the jassid insect is responsible for spreading the contagion The Corporation is now considering the desirability of breeding jassid resistant strains in the Sudan

The Corporation, during the first years of its activities, found difficulty in obtaining agricultural scientific officers of adequate experience, but it is pleasing to note that it is now able to arrange for its senior officers to visit cotton growing localities outside their own charge Much good is expected of this interchange of thought and knowledge born of long experience, and the scheme should stimulate the younger officers who are striving to make head way in recently opened cotton growing areas

It is unfortunate that the continued depression in the cotton industry has made it necessary to reduce the spinners' levy from 3d to 1d per 500 lb of raw cotton, but the Corporation will be able to carry out its full programme for the coming year by drawing on its accumulated reserves The burden on the Corporation has been reduced in recent years by the increasing share that colonial governments are now taking in the cost of developing cotton growing, and also because the Colonial Office is now training men for agricultural appointments on the lines initiated by the Corporation F P S

Meteorological Conditions accompanying a Waterspout

AT 9 31 A M, on June 14, 1929, a waterspout formed over Pensacola Bay, Florida, three hours after Lieut P G Hale of the U S Navy had obtained accurate records of the pressure, temperature, and humidity of the atmosphere up to a height of 3000 metres close to the place where the spout developed Mr Hale also secured an admirable photograph of the phenomenon, taken from an aeroplane, which shows that the spout took the usual form of a sharply defined cord like cloud stretching in a rather sinuous curve from the base of a cumulo nimbus cloud to the sea, with a cloud of spray at its base

At the time of the sounding, there was a dust horizon to the east at a height of about 2800 metres, and tall cumulus clouds were thrusting their heads through the haze top Additional evidence of atmospheric instability was furnished by the graph of temperature and entropy plotted on a Shaw 'tephigram', which is reproduced together with the photograph in a short article in the *Monthly Weather Review* for August 1929 The article is of especial interest, owing to the attention directed to the subject by Wegener's recent introduction of the theory that the visible part of a waterspout is the extension of a whirl with a horizontal axis within the parent cumulo nimbus cloud, and also because the chances are so against an aerial sounding happening to be made such a short time before the occurrence of a spout

The 'tephigram' reveals an atmospheric environment such that a very moderate amount of general heating of the lower layers of the atmosphere, or, alternatively, a slight increase of their water vapour near the surface, would allow any portion of the surface air with a little extra warmth or moisture to ascend automatically It shows, further, that the ascending air would have possessed a large amount of surplus energy beyond that required merely for its ascent, such energy being available for developing the kinetic energy corresponding with the violent winds around the axis of a waterspout This is the kind of information that a glance at the 'tephigram' will reveal to anyone familiar with it

When we read that the construction of a 'tephigram' is a matter of daily routine for weather forecasting at the Pensacola air station, it becomes clear that the thermodynamical researches of Carnot, Clausius, Maxwell, and others are beginning - mainly owing to Von Bezold in Germany and Napier Shaw in Great Britain—to have novel fields of practical application

University and Educational Intelligence

BIRMINGHAM —The annual meeting of the Court of Governors of the University is to be held on Feb 27, and the reports of the Vice Chancellor and the Council, which are to be presented to the Court, have been issued The Vice Chancellor, Sir Charles Grant Robertson, reviews the changes which have occurred during the ten years of his tenure of office and is able to report much progress The income and expenditure have greatly increased, and it is satisfactory to note that the largest item of expenditure is that of salaries Nine members of the non professional staff have been promoted to Grade I with a minimum salary of £600 a year—a reform long overdue The number of students continues to increase slowly

The eighth annual report of the Joint Standing Committee for Research shows an imposing array of subjects of research in aid of which grants have been made, and enumerates the publications of the various departments of the faculties of science, arts, medicine, commerce, and law The report indicates a healthy activity in research over a wide range of subjects

The event of the greatest moment to the University is the development of the new hospital scheme, in which an important step has been taken in the selection of plans for the buildings If the money is forthcoming (£1,000,000 has been mentioned) a magnificent group of buildings will arise, on a site near to the University grounds, to accommodate the hospital and the University Medical School

CAMBRIDGE —Mr W R Dean, of Trinity College, has been appointed University lecturer in mathematics

LONDON —The Court of the University has gratefully accepted a bequest by the late Lady Durning Lawrence of £10,000 for the equipment of the Physical and Electrical Chemistry Laboratory at University College

NOTICE is given by the University of Wales that five fellowships, each of the annual value of £200 and tenable for two years, are to be awarded during the present year to graduates of the University Applications for the fellowships should be sent by June 1 to the Registrar, University Registry, Cathays Park, Cardiff

Historic Natural Events

Feb 23, 1887 Earthquake—The Riviera earthquake was not one of great strength, for only 640 persons were killed, while the area disturbed contained 219,000 sq miles The earthquake is, however, interesting on two accounts It was one of the early earthquakes in which the existence of two foci was recognised It was also one of the first to be registered by instruments far beyond the disturbed area, magnetographs being displaced at Kew, Wilhelmshaven, and Lisbon, which are respectively 652, 690, and 951 miles from the epicentre

Feb 24, 1575 Flood of Flies and Beetles—According to Holinshed, at Tewkesbury, "after a flood which was not great, but such as thereby the meadows near adjoining were covered with water, in the afternoon there came down the river of Severn great numbers of flies and beetles, such as in summer evenings use to strike men in the face, in great heaps, a foot thick above the water, so that to credible men's judgments there were seen, within a pair of butt's length, of those flies above a hundred quarters The mills thereabouts were dammed up with them for the space of four days after, and then were cleansed by digging them out with shovels From whence they came is yet unknown, but the day was cold and a hard frost"

Feb 24, 1844 Mild Winter—"I tell you that we have had the mildest winter known The extraordinary fine season has killed heaps of people with influenza, debilitated others for their lives long, worried everybody with colds, etc"—FITZGERALD

Feb 26, 1658 Severe Winter—The winter of 1657–8 was very rigorous On Feb 26 Charles X of Sweden crossed from Fuenen to Zealand across the ice, with all his army, cavalry, artillery, and baggage The ports of Ostend and Sluys were blocked by ice, and even in Italy the rivers were frozen so solidly that they supported the heaviest carriages In Rome at the beginning of February was the greatest snowfall of the century The Seine was frozen, and the thaw was followed by a flood on Feb 27–28, greater than any previously recorded In England the cold was severe, with persistent northerly and northeasterly winds On Mar 7, Evelyn wrote "This had been the severest winter that any man alive had known in England" Spring appears also to have been backward, for on June 12 he wrote "The season as cold as winter, the wind northerly near six months"

Feb 26–27, 1903 Gale—On the night of Feb 26 and the morning of Feb 27 a deep barometric depression travelled north eastwards across the British Isles The barometer fell below 958 mb (28 3 inches) and the winds reached nearly 90 miles per hour in squalls The south westerly gale over Ireland was described as the most violent since the 'big wind' of Jan 6, 1839, thousands of trees were uprooted and much damage was done to buildings On Leven Viaduct, near Ulverston, a train consisting of ten passenger coaches and vans was overturned by the force of the wind

Feb 28, 1540 Beginning of Great Drought—The year 1540 was extremely hot and dry both in England and in central Europe, probably the hottest on record and comparable for drought with 1000 and 1473 In England rain fell only six times between February and Sept 19, and in Zurich only four times during the same period In Regensburg and Milan there was practically no rain for five months In Switzerland it was known for a century as 'the hot summer' The following year, 1541, was also very dry in England, and the combined effect of these two years had serious consequences Almost all the small rivers dried up, the River Trent diminished to a straggling brook, and the Thames fell so low that even at ebb tide sea water extended beyond London Bridge—an unheard of phenomenon at that time Many cattle died for want of water, especially in Nottinghamshire, and many thousands of persons died from grievous diarrhœa and dysentery

Societies and Academies

LONDON

Royal Society, Feb 13—**G Slater** Studies on the Rhone Glacier, 1927 The structure of the ice in a compressed zone on the south eastern part of the glacier This zone is marked by a series of ridges dissected by three crevassed longitudinal basins The structure of the easterly ridge, which was plotted to scale, showed a complete disarrangement of the normal ribbon structure, the ice being dissected into blocks by thrust planes The general strike of the thrust planes suggests a deviation of the ice southwards from the normal south westerly movement of the glacier Relief from pressure was obtained by upward movement along thrust planes, and by lateral squeezing towards the tensional areas The structure developed in the glacier is the same in principle as that of the disturbed Pleistocene drift deposits of Europe and America —**T Goodey** On a remarkable new nematode *Tylenchinema oscinellæ* gen et sp n, parasitic in the frit fly, *Oscinella frit* L, attacking oats The parasite is widely distributed in England and Wales, its life history and the development of the gonad for both sexes are described The general result for the host is sterilisation —**D E Sladden** Distortion of development in amphibia caused by lack of oxygen in very early stages in development Eggs of the common frog deprived of oxygen, either by sugar solution or by reduced air pressure, gave rise to tadpoles showing various types of abnormalities The abnormalities present at the time of hatching died shortly after, leaving only apparently normal larvæ. From among these, however, after a period of about eight weeks, abnormalities showing flexure in tail, distortion of sacral region, and in one case suppression of hind limb, made their appearance These latter were successfully reared through metamorphoses —**Sir Frederick Keeble, M G Nelson, and R Snow**—The integration of plant behaviour (Pt 2) The influence of the shoot on the growth of roots in seedlings By removing the shoot in young pea seedlings or the shoot and coleoptile in young maize seedlings, the growth of the main root is slightly increased for a few days, but the growth of secondary or adventitious roots is very greatly decreased By removal of the coleoptile alone in young maize seedlings, the growth of adventitious roots is decreased, but to a much less extent —**A W Greenwood and J S S Blyth** The results of testicular transplantation in brown Leghorn hens Persistent grafts of testicular substance have been obtained in a series of normal hens Modification in the functions of the ovary have been produced, both in regard to the production of eggs and to the development of the secondary sex characters

Geological Society, Jan 22—**J W Gregory, Ethel Dobbie Currie, J Weir, S Williams, and G W Tyrrell** On the geological collection from the South Central Sahara made by Mr Francis Rodd The Aïr Massif in the South Central Sahara was shown by the work of Barth (1857) and Chudeau (1907, etc) to consist of a foundation of gneiss, schist, and granite, on which rest in the north and west sheets of Devonian marine beds,

and in the south Cretaceous limestones and subaerial sandstones The gneiss and schists are probably pre Palæozoic At In Nuguren, west of the Aïr massif, there are well-preserved Turonian fossils affording evidence of a connexion of the sea in Angola with that of the Mediterranean across the Central Sahara Some terrestrial deposits earlier than the Turonian limestones contain silicified fossil wood identified as *Dadoxylon* The igneous rocks collected represent a northern extension of the Kainozoic volcanic series of Kenya and Kordofan The Cretaceous limestones indicate that the Central Sahara was partly submerged by a Turonian transgression, which connected the Angola Gulf and the Lower Niger with Tunisia It had a branch westward through In Nuguren towards the Middle Niger, but had no known connexion across Abyssinia with Somaliland or the Gulf of Aden —**J V Harrison** The geology of some salt plugs in Laristan (Southern Persia) The area is contained in the rectangle between lat 27° and lat 28° 20′ N, and long 54° 20′ and long 57° E Much of the district is covered by normally folded rocks which range in age from Ordovician to Recent, and reach an aggregate thickness of 25,000 feet The only general angular unconformity occurs high in the Mio Pliocene On the north and east the frontal part of the nappes overrides and ploughs into the normally folded rocks South and west of the line of nappes the normal folds have been invaded by plugs of salt, which have brought up quantities of gypsum and blocks of sedimentary and igneous rocks The extrusive salt has come to the surface at different times, from Oligocene to late Mio Pliocene The intrusive salt masses, sheathed with autochthonous sediments tilted around them, form, in some cases, brightly coloured mountains of very striking and characteristic appearance The formation of the salt plugs is attributed to tangential forces acting on Cambrian salt, which, on account of its comparative plasticity, has acted as something analogous to an igneous magma in its behaviour

Paris

Academy of Sciences, Jan 13 —The president announced the death of Auguste Rateau —**Ch Fabry and E Dubreuil** A supposed transformation of lead by the effect of solar radiations Criticism and correction of some results recently published by Mlle S Maracineanu No trace of either gold or mercury could be found in the specimens of lead examined —**Ch Achard and M Enachesco** The reciprocal action of chlorination and alkalinisation of the organism in acute diseases —**Maurice de Broglie** The use of gratings at grazing incidence for spectrophotography of the extreme ultra violet J Thibaud was the first to apply the use of a grating at grazing incidence to the study of the radiations in the ultra violet An account is given of subsequent developments of the method, with special reference to the X rays —**Pierre Weiss** The diamagnetism of the ions —**S Lefschetz** Continued transformations of closed ensembles and their fixed points —**Marcel Brelot** The exterior problem of Dirichlet for the equation $\Delta u = c(x, y)u(x, y)(c>0)$ —**A Métral** An essential character of conformal representations utilisable for planning the profiles of the wings of aeroplanes —**Carl Störmer** The absence of retarded (wireless) echoes during totality of the eclipse of May 9 in Indo China —**L Gaurier** The alteration of the alluvium of lakes converted into reservoirs —**L Pirot** The deviation from the vertical round the peninsula of Brittany —**Guichard, Clausmann, and Billon** The variations of the hardness of certain metals and alloys as a function of cold hardening —**Carl Benedicks** The density of some iron alloys in the liquid state —**Edlén and Ericson** The condensed spark spectrum in the extreme ultra violet to 88 A —**Georges Fournier** An arithmetical relation between the atomic weight and the atomic number —**P Mondain-Monval and Pierre Galet** The anomalies of the physical properties of the vitreous state The case of amorphous sulphur and selenium The viscosity measurements of sulphur, which were made by a form of penetrometer, showed a sharp change in viscosity at - 21° C a study of the density changes showed a point of transformation at - 20° C Similar measurements with selenium gave a clear point of inflection on the viscosity curve at 45° C and on the density curve at 31° 33° C As in the case of glass, at a temperature slightly below the softening point, sulphur and selenium undergo an allotropic transformation this takes place with a diminution of viscosity, an increase in the coefficient of expansion, and a sensible heat absorption —**Pierre Brun** The boiling points of aqueous alcoholic liquid mixtures Experiments on ternary mixtures of water, ethyl alcohol, and isoamyl alcohol have been made and the results given in a triangular diagram —**Maurice François** The action of concentrated ammonia on the compound $HgBr_2 2NH_3$ The formation of HgH_2NBr and Hg_2NBr —**Marcel Guillot** An attempt to prove the existence of a non electrolytic complex of polonium The experiments described point to the probable existence of a complex substance of the formula $Po(-S-CS-NR_2)_2$ —**Daniel Schnéegans** The presence of radiolarites in the Briançonnais sheet —**Pierre Dangeard** The influence of oxygen in iodo volatilisation Experimental proof that gaseous oxygen is necessary for the emission of iodine by *Laminaria* It is suggested that the negative results obtained by H Kylin were due to the non recognition of this fact —**Raymond-Hamet** The action of ouabaine on the intestine *in situ* The intestine when isolated is contracted by ouabaine, but the intestine *in situ* is relaxed by the alkaloid —**J Enselme** Contribution to the study of the acid hydrolysis of the proteids —**Mme Phisalix** Natural immunity against snake poison and the virus of rabies of the common dormouse, *Eliomys nitela* This animal shows no sign of poisoning after being bitten by the viper In battles between the dormouse and the viper, the former always takes the offensive and the snake is invariably killed The dormouse is also immune to intra muscular injections of the rabies virus The serum of the dormouse *in vitro* neutralised the rabic virus The immunity of this animal towards both snake poison and the virus of rabies is due to the existence in the blood of anti substances

Geneva

Society of Physics and Natural History, Dec 19 —**F Chodat** A new demonstration of the Traube cell The author proves the penetration of water into the semi permeable copper ferrocyanide membrane cell The progressive flocculation of egg albumen incorporated in the cell allows the measurement by nephelometry of the velocity of penetration by the water —**Ed Parejas** Would the Geneva basin lend itself to a study of glacial varves? The author, from the researches which he has made in the eastern part of the Lake of Geneva, considers it probable that the Geneva basin (western part) would lend itself, by the study of the varves, to an attempt at the synchronisation of the Alpine and Scandinavian post glacial deposits —**G Tiercy** On four 'mean' curves relative to the Cepheids The author has recently terminated the study of two variable stars of the Cepheid type, he proves that the new results agree very well with those that he has previously obtained for other Cepheids

Diary of Societies

FRIDAY FEBRUARY 21

TEXTILE INSTITUTE (Lancashire Section) (at Textile Institute Manchester) at 1 15 —J Smeaton Textile Specifications and their Preparation

ASSOCIATION OF ECONOMIC BIOLOGISTS (in Botany Lecture Room, Imperial College of Science and Technology), at 2 30 —Dr W R Thompson Biological Control of Injurious Insects and Weeds

GEOLOGICAL SOCIETY OF LONDON (Annual General Meeting) at 3 — Presidential Address

DIESEL ENGINE USERS ASSOCIATION (at Caxton Hall) at 3 30 —Report of the Committee on Heavy Oil Engine Working Costs 1928–29

LONDON SOCIETY (at Royal Society of Arts), at 5 —Sir Frank Dyson The Royal Observatory Greenwich

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION (Annual General Meeting) (at 11 Chandos Street W 1) at —Dr G E Friend Some Notes on the Value of Clinical Dietetic, and Physical Records in Public Schools (Presidential Address)

ROYAL SOCIETY OF MEDICINE (Balneology Section) at 5 —Dr J B Burt and others Discussion on Bath Reaction in Spa Treatment

BRITISH INSTITUTE OF RADIOLOGY (Medical Meeting) at 5 —Radiology in Gastrointestinal Diseases

ROYAL COLLEGE OF SURGEONS OF ENGLAND at 5 E R Flint The Association between Gall Bladder Lesions and Hepatitis in the Human Subject

SOCIETY OF CHEMICAL INDUSTRY (Liverpool Section) (jointly with Manchester Section) (at Liverpool University) at 6 —J Twomey Flour Milling

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute Newcastle upon Tyne) at 6 —Rear Admiral W Scott Hill Powdered Coal for Ship Propulsion

INSTITUTION OF MECHANICAL ENGINEERS (Annual General Meeting), at 6 — Annual Report Discussion on Sixth Report of the Steam Nozzles Research Committee

INSTITUTION OF ELECTRICAL ENGINEERS (London Students Section) at 6 15 —S H Hurt Paper insulated Power Cables

TEXTILE INSTITUTE (London Section) (at Chemical Society), at 6 45 — F T Goodall Diagnosis of Colour Faults in Finished Goods

BENSON CLUB (at Armstrong College, Newcastle upon Tyne) at 6 30 — Sir James Walker Kolbe s Electrosynthesis (Bedson Lecture)

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group— Informal Meeting), at 7 —R H Lawton Pictorial Essentials

GEOLOGISTS ASSOCIATION (North East Lancashire Group) (at Blackburn Technical College) at 7 —Miss E T Wooff A Visit to East Sutherland

JUNIOR INSTITUTION OF ENGINEERS at 7 30 —E P S Gardner The Application of Electric Welding to the Erection and Strengthening of Steel Structures

ROYAL SOCIETY OF MEDICINE (Obstetrics and Electro Therapeutics Sections) at 8 —Special Discussion on The Position of Radium in Treatment of Gynæcological Conditions Openers M Donaldson and S Dodd Obstetrics Dr A E H Pinch and Dr J F A Lynham, Electro Therapeutics

ROYAL INSTITUTION OF GREAT BRITAIN, at 9 —J B S Haldane Principles of Plant Breeding

SOCIETY OF DYERS AND COLOURISTS (Manchester Section) (at Manchester) —Prof McSwiney The Problem of the Fastness of Dyes to Perspiration

SATURDAY FEBRUARY 22

GEOLOGISTS ASSOCIATION (in Natural History Museum, South Kensington), at 2 30 —Dr W D Lang Demonstration of Palaeontology and the Public

NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS (Newcastle upon Tyne), at 2 30 —G E Tansley The Value of the Economiser in Present Day Boiler Installations —C Howson Notes on a Winding Accident at Mainsforth Colliery — Exhibition and Demonstration by E Smith of the McLuckie Gas Detector —Discussion upon Report of an Investigation of the Underground Conveying and Loading of Coal by Mechanical Means

ESSEX FIELD CLUB (at West Ham Municipal College), at 3 —Celebration of 50th Anniversary

ROYAL INSTITUTION OF GREAT BRITAIN at 3 —W Rothenstein Nineteenth Century Painting in France and England (I)

OXFORD UNIVERSITY JUNIOR SCIENTIFIC CLUB.—Exhibition Meeting

MONDAY, FEBRUARY 24

INSTITUTE OF ACTUARIES, at 5 —L K Elle Disability Benefits in Conjunction with Life Insurance Policies

KING S COLLEGE ENGINEERING SOCIETY (at King s College), at 5 15 —B E Willett Railway Permanent Way

INSTITUTION OF ELECTRICAL ENGINEERS (North Eastern Centre) (at Armstrong College Newcastle upon Tyne) at 7 —Informal Discussion

INSTITUTE OF CHEMISTRY (Leeds Area Section) (at Great Northern Hotel, Leeds), at 7 15 —R. L Collett and others Discussion on The Institute and the Chemical Profession

Keighley Textile Society (at Kiosk Café, Keighley), at 7 30.—H Jennison The Dyeing and Finishing of Costume Cloths.
Royal Society of Arts, at 8.—A B Searle Recent Improvements in Methods of Brickmaking (Cantor Lectures) (2).
Medical Society of London, at 8 —Col L W Harrison and others Discussion on The Treatment of Syphilis.
Royal Society of Medicine (Odontology Section), at 8 —Dr G Villain The Problem of Stabilisation and Articulation of Dentures
Royal Geographical Society (at Æolian Hall), at 8 30 —H R H the Duke of Spoleto The Italian Expedition to the Karakoram.
Cambridge Philosophical Society (in Botany School), at 8.45 —Prof E. A. Milne The Principles of Radiative and Convective Equilibrium, and their Application to the Sun and Sun spots —*Papers to be communicated by title only* —Sir J Larmor The Law of Stifling of Sound by Curtains —J B S. Haldane A Mathematical Theory of Natural and Artificial Selection. Part VI Isolation —Dr H Jeffreys The Draining of a Flat Plate —S. Verblunsky Note on the Gibbs Phenomenon.—Dr W R G Atkins and Dr H H Poole Methods for the Measurement of Daylight. —Pol Gérard Sur l'histophysiologie des annexes fœtales des mammifères —Dr Muriel Elaine Robinson Cyanogenesis in Plants —Dr J Needham The Biochemical Aspect of the Recapitulation Theory —J Henderson Smith Virus Diseases in Plants —Prof W Stiles Viscosity of Protoplasm as Determining the Rate of Biological Reactions.
Royal Aeronautical Society (at Northampton Engineering College).—C R Fairey Aviation (Walmsley Memorial Lecture)
Paper Makers Association (Technical Section Northern Division) (at Engineers Club, Manchester).—S Richardson Removable Fourdrinier and New Mechanical Drive
Royal Irish Academy (Dublin)

TUESDAY, February 25

Royal Dublin Society (at Balls Bridge, Dublin), at 4 15 —Dr W R. G Atkins Some Geo Chemical Applications of Measurements of Hydrogen Ion Concentration A W Stelfox Explorations at Kilgreany Cave Co Waterford —Prof J Reilly, P J Drumm and T Gray The Nitration of Substituted Diaryl Ethers
Royal Society of Arts (Dominions and Colonies Meeting), at 4 30 —Dr A. W Hill Scientific and Industrial Research in the British Empire
Royal Society of Medicine (Medicine Section), at 5 —Dr F G Chandler A T Edwards, Dr L S T Burrell and J E H Roberts Discussion on The Treatment of Lung Abscess
Royal Institution of Great Britain, at 5 15 —Sir William Bragg X Ray Determination of the Structure of Cellulose and Similar Substances (3).
Institution of Civil Engineers at 6 —C J R Williams The Development of Lyttelton Harbour, New Zealand —R F Hindmarsh Tyne Commission Quay North Shields —R C Bristow Cochin Harbour Works
Institution of Electrical Engineers (North Midland Centre) (at Hotel Metropole, Leeds), at 7 —L C Grant The Breaking Performance of High Power Switchgear and of a New Form of Quenched Arc Switch
Royal Photographic Society of Great Britain (Scientific and Technical Group) at 7 —Dr W Payman The Applications of Photography in Explosives Research
Institution of Engineers and Shipbuilders in Scotland (at 39 Elmbank Crescent Glasgow), at 7 30 —J W W Drysdale Marine Salvage Pumping
North East Coast Institution of Engineers and Shipbuilders (Teesside Branch—Graduate Section), at 7 30 —J Walton Some Large Span Modern Bridges and their Erection
British Psychological Society (Industrial Section) (at National Institute of Industrial Psychology) at 8 15 —Marion Milner Some American Approaches to the Study of Temperament.
Royal Anthropological Institute, at 8 30 —F W H Migeod Primitive Pictorial Art in Africa at the Present Day
West Kent Scientific Society (Annual Meeting) (at Wesleyan Hall, Blackheath), at 8 30

WEDNESDAY, February 26.

Royal Society of Medicine (Comparative Medicine Section), at 5 —Discussion on The Present Position of Distemper Inoculation
Eugenics Society (at Royal Society), at 5 15 —Dr B P Wiesner Hormones controlling Reproduction
Geological Society of London at 5 30.—S E Hollingworth The Glaciation of Western Edenside and Adjoining Areas, and the Drumlins of Edenside and the Solway Basin
Liverpool Engineering Society (at 9 The Temple, 24 Dale Street, Liverpool), at 6 30 —W Hinchcliffe Some Data relating to Modern Ships' Performance in Service
Institution of Automobile Engineers (Manchester Centre) (at Engineers Club, Manchester), at 7 —L H Pomeroy The Double Six Engine.
North East Coast Institution of Engineers and Shipbuilders (Graduate Section) (at Bolbec Hall, Newcastle upon Tyne), at 7 15 —L C Burrill Some Notes on Stability
Halifax Textile Society (at White Swan Hotel, Halifax), at 7 30 —J Hill Calculations as applied to Weaving.
Royal Society of Arts at 8 —Prof F A. E Crew Genetical Methods of Live Stock Development.
British Psychological Society (Medical Section) (at Royal Society of Medicine), at 8.30 —Dr M D Eder On the Psychology of Values.

THURSDAY, February 27

King's College Engineering Society (at King's College), at 5 15 —B C Mathieson Modern Practice in the Manufacture of Portland Cement.
Royal Institution of Great Britain, at 5 15 —J B. S. Haldane Some Problems of Genetics.
University of London Animal Welfare Society (at Royal Veterinary College), at 5.15 —B M Batten, J H Driberg, and others Public Discussion on The Problem of Trapping.

Institution of Electrical Engineers, at 6.—Capt P P Eckersley Broadcasting by Electric Waves (Faraday Lecture).
Institute of Metals (Birmingham Local Section) (at Chamber of Commerce, Birmingham), at 7 —R. W Bailey Creep of Metals at High Temperatures.
Royal Aeronautical Society (Jointly with Institution of Automobile Engineers) (at Royal Society of Arts), at 7 45 —A J Rowledge Latest Developments of Aero Engine Practice
Institution of Welding Engineers (at Caxton Hall), at 7 45 —J Ryder The Training of Operators in the Welding and Cutting Industries
Royal Aeronautical Society (Yeovil Branch) (at Yeovil).—Racing Sea planes (Lecture).
Royal Society of Medicine (Urology Section) (at Liverpool).
Oxford University Junior Scientific Club.—S Sugden Higher Valencies and the Parachor
Institute of Rubber Technologists (at Manchester Café, Ltd , Manchester) —Short Papers

FRIDAY, February 28.

Electrical Association for Women (at 46 Kensington Court) at 3 —L L Robinson Tariffs
Royal Society of Medicine (Epidemiology Section), at 5 —Sir Leonard Rogers Further Experience in Forecasting Epidemics in India and their Bearing on the Reduction of Cholera Epidemics
Physical Society (at Imperial College of Science), at 5 —C H N Lock The Equations of Motion of a Viscous Fluid in Tensor Notation —W L Watton A New Type of Dewar Flask for Use as a Calorimeter —R O Cherry Field Intensity Measurements around some Australian Broadcasting Stations
Junior Institution of Engineers (Informal Meeting) at 7 30 —J Rowcroft The Design of Dynamos for Automobiles
Royal Institution of Great Britain at 9 —Prof G I Taylor A Tour in the East Indies
Institution of Electrical Engineers (West Wales—Swansea—Sub Centre).—L C Grant The Breaking Performance of High Power Switch gear and of a New Form of Quenched Arc Switch

SATURDAY March 1

Geologists Association (at Museum of Practical Geology, Jermyn Street) at 2 30 —C P Chatwin Demonstration of The Palæontology of the Reigate Sheet
Royal Institution of Great Britain, at 3 —W Rothenstein Nineteenth Century Painting in France and England (2)
Mathematical Association (London Branch) (at Bedford College) at 3 —Prof W M Roberts Energy and some Points in St tics
Gilbert White Fellowship (at Queen Square, W C 1), at 3 —Conversazione and Exhibition

PUBLIC LECTURES

FRIDAY, February 21

King's College, at 5 30—Sir Rennell Rodd Survivals of Ancient Myth in Modern Greek Folk lore
Surveyors Institution at 5 30 —R A Watson Watt What is wrong with Wireless? (Lecture in connexion with Institution of Professional Civil Servants)

SATURDAY February 22

Horniman Museum (Forest Hill), at 3 30 —Miss I D Thornley Sanctuary in the Middle Ages

MONDAY February 24

King's College, at 4 30 —Prof E Prestage Portuguese Voyages of Discovery and Empire Building (Succeeding Lectures on Mar 3, 10, and 17)
University of Leeds at 5 15 —Dr J Chadwick Nuclear Physics

WEDNESDAY, February 26

University College at 5 30 —K G Hunt The Librarian's Problem of Catering for the Student
Belfast Museum, at 8 —C R Nodder Soap Bubbles

FRIDAY, February 28

Imperial College of Science and Technology (Department of Mathematics), at 5 30 —Prof C Størmer The Mathematical Theory of the Polar Aurora. (Succeeding Lectures on Mar 5 and 7)
University College at 5 30 —Prof E Gilson L'idée de Dieu dans la Philosophie de Descartes. (Succeeding Lecture on Mar 3)

SATURDAY March 1

Horniman Museum (Forest Hill), at 3 30 —Dr W G Ivens The Solomon Islands and their People

CONFERENCE.

February 28 and March 1

Association of Technical Institutions (at Skinners Hall, Dowgate Hill, E C 4).
Friday February 28, at 10.30 a.m —Lord Eustace Percy Presidential Address —C R. Keene The Relationship between the Teaching of Art and Technology
Friday, February 28 (*afternoon*), and *Saturday, March* 1 (*morning*) —F W Goodenough The Teaching of Salesmanship in Technical Colleges —G H Gater A Descriptive Account of Technical Education in London —E Salter Davies, Sir Percy Jackson, and Principal J H Everett The Raising of the School Leaving Age and its Effect upon Technical Education —Principal R S. Clay and others Discussion on Technical Education for the Plumbing Trade, with Special Reference to the Rural Apprentice.

International Congresses

WHEN is a congress international? Still more, when is it 'truly international', as well as international in name? At first sight the question is one of nomenclature, but it covers one of principle, and of discrepant practices It has also been brought momentarily into prominence in a special case by a presidential address which, though nominally addressed to one of our 'learned societies', was in a sense encyclical [1]

Apart from œcumenical councils of—as yet—undivided Christianity, and uniformly unsuccessful attempts to 'get both sides together' in later schisms, international congresses are of recent invention, a product of an 'industrial age', with its facilities for organised study and intercommunication National conferences, such as the British Association, are meditating their centenary, few international congresses have had a jubilee, though the oldest, that were designed to be periodic, go back into the 'sixties

Even before the War, there were two grades of such congresses, one summoned by a government or governments, was composed of official delegations representing nations as such, the other was a privately arranged meeting of fellow workers in a particular branch of learning, usually convened by a leading society or institution in some one country in the name of colleagues there Naturally there were hybrids, as when a government either selected or recognised one or more of its nationals, attending a private congress, to express its goodwill, and even to concert practical measures for its own subsequent consideration

Of the status of a congress convened by invitation of one recognised government to all others, there can be no question, it is 'inter-national', a conference between representatives of nations, if there are absentees or defaulters, "the unworthiness of the minister affecteth not the efficacy of the sacrament" Also, naturally, private conferences have courted the prestige of official patronage, even when it did not bring the substantial encouragement of a subsidy

Before the War, private international congresses, however periodic by custom, were usually organised by a body of nationals of the country to which the

[1] "Anthropology National and International Presidential Address of Prof John L Myres to the Royal Anthropological Institute of Great Britain Jan 28, 1930

congress was invited, and in which it was to be more or less gratuitously entertained This had the obvious advantage that the hosts were neighbours accustomed to work together as a team, they knew local conditions, and were the persons most deeply engaged to make the meeting a success In such meetings effective international co-operation usually began only when the members assembled, and ceased after the 'butter meeting', leaving the national committee to publish 'proceedings' and pay the bills In countries where the law of associations is strict, it was necessary to incorporate a joint-stock company to hold and expend subscriptions, but its duration as well as its liability was 'limited', and in due course it went into voluntary liquidation, the doctrine of *cy-près* governing the disposal of assets, if any, either to endow research locally, or to be nest-egg for the next congress To receive such cash balance, however, some similar body had to come into existence, and accordingly some congresses established a 'permanent committee', either of nationals of the country the invitation of which for next meeting the defunct congress had accepted, or of a few eminent members irrespective of nationality In the latter event, *de minimis non curabat lex* outgoing and incoming treasurers were presumably both just and solvent, and pre War congresses were oftener insolvent than intestate

What was more difficult was to give effect to the *vœux* or resolutions of such international meetings It was all very well to refer them to a multi national committee but that way the Tower of Babel fell *quis committeret commissionem?* Again the solution, found slowly and tentatively, was in an inter-congressional executive or 'bureau'

Now, concurrently with this trend towards continuity between successive congresses, there was perceptible from about 1899 onwards, similar trend towards coherence between the leading 'learned societies' of civilised countries, towards inter-academic correlation of workers, methods, and results But an adolescent International Association of Academies, complicated by the existence of rather many academies in some countries, and of fewer, or none, in others, was suspended by the War, and the failure to resuscitate it at the Peace left both academies and congresses in chaos aggravated by a tangle

In October 1918 an 'inter-allied' conference in London called on 'allied and associated' countries to denounce all international scientific associations in which they had participated before the War It was a "drastic, and perhaps necessary act of sabotage", but it cleared the ground for the International Research Council which was established in 1919 But the International Research Council was not (at the outset) inter-national, but, at best, inter allied-and-associated This drawback was, however, remediable, in time It was a further complication that a permanent body, as the I R C was intended to be, had to have domicile some where, and the *siège social* of the I R C was, and is, in Brussels, incorporated under Belgian law The League of Nations, with domicile in Geneva, had not come into being yet

Now it was a prime function of the I R C to establish (1) national unions for collaboration in the several sciences, (2) inter national congresses between the national unions in any science, all deriving sanction and status from the I R C This was no doubt why countries adhering to the I R C were to forswear allegiance to all pre War congresses Such unions and congresses have been in due course formed and held in certain sciences, under the sanction of the I R C

What, however, governments or academies adhered to, or forswore, left many nationals—and even fellows of learned societies—unimpressed In some subjects, where the resumption of collaborated observations, in as many countries as possible, was urgent, national unions, and more or less international congresses, sprang into being forthwith In others, "time, the great reformer", has been also the great restorer of normality One series after another of the pre War congresses has been quietly revived, as soon as people felt like meeting again, and no one has been sent to the Tower for this, or excommunicated from a *siège social* anywhere

More than this, the League of Nations, through its International Committee for Intellectual Co-operation, has summoned another type of international congress—for example, at Prague in 1928 for 'popular arts', making use of a body, domiciled in Paris, and subsidised by the French Government, the International Institute for Intellectual Co-operation, the precise relations of which to the International Committee of the League at Geneva scarcely concern us here In this League type of

congress, a general assembly of members at the place of meeting elects a general committee, including many nationalities The members of this committee domiciled in Paris form a 'permanent bureau' for business between congresses, and the secretariat is supplied by the Paris Institute abovementioned Hereby the inter national character of the periodic congresses and their general assembly is assured and maintained, the local arrangements for successive congresses are made by a temporary local committee in the inviting country, as under pre War conditions while continuity in administration and collaboration in research are ensured through the liberality of the French Government and the goodwill of members resident in Paris, all under specific sanction from an international committee of the League of Nations

In anthropology, *fons et origo* of this meditation, an arrangement, superficially similar, presents, on closer examination, divergent features, which appear to have disquieted some of those concerned—not in Great Britain only Within a few days after the Armistice, an eminent institution for anthropological teaching and research, the 'École d'anthropologie' in Paris, convened a conference, attended by representatives of twelve countries, at which was founded, under the title 'Institut International d'Anthropologie', an association, domiciled in Paris, on the premises of the 'École', for "grouping, coordinating, and centralising the efforts of all persons engaged in anthropological problems, provided that they are accepted by its 'Conseil d'administration'" (or, as one of the speakers put it, "sauf l'exception que vous savez"), which, under French law regulating incorporated bodies, necessarily contains a large proportion of French nationals, and was deliberately so constituted at the first conference Actually this 'Conseil' includes twenty six Frenchmen with not more than four representatives of any other country up to a maximum of fifty Naturally, any country which desires effective representation on a body which meets in Paris most easily secures this if it is represented by Paris residents The president and treasurer of this 'Institut' must be French subjects, and the secretaries are nominated by the management of the École d'anthropologie

One, but by no means the only, function of this 'Institut' is the organisation in various countries of congresses *of its members* elected by the 'Conseil' in Paris, paying a subscription, and receiving the periodical *Révue d'anthropologie* published by the teaching staff of the Paris École, this provides the management with a means of publication for proceedings, announcements, and the like These 'adherents' in some countries have formed 'autonomous offices' rather like the 'national unions' of the I R C, except that they are solely composed of individual subscribers or affiliated societies, accepted by the 'Conseil' in Paris For each congress there is in future to be an 'international' committee, consisting of one member for each country, but its functions are advisory, not executive Countries which do not 'adhere' to the 'Institut' are nevertheless provided with a representative by the 'Conseil' Congresses of this series have been held at Liège in 1921, at Prague in 1924, and at Amsterdam in 1927, and it is reported that a similar congress is being arranged at Lisbon in 1930

At the Amsterdam congress, survivors of the pre War series of 'Congrès d'anthropologie et d'archéologie prehistoriques' (which dates back to 1867), and representatives of the Royal Anthropological Institute, discussed with colleagues of French and other nationalities the future relations between the old and the new congress organisations, and also between the Paris 'Institut' and the new series of congresses and in the following years practical fusion has been effected between the old and new series of congresses, so that it would now be possible for a congress organised on the pre War model to be convened and prepared 'par les soins de l'Institut International d'Anthropologie', without being so wholly governed by that not very international body as the present statutes prescribe

What the Paris 'Institut' may decide is a matter of immediate interest, for its adherents appear to have been informed that there is to be a congress in Lisbon in September next Presumably the moment will come when anthropologists, other than subscribing 'adherents' of the 'Institut', will have official intimation of it Governments of other nations may be invited to send delegates, as some governments did send delegates to Amsterdam But it would seem an open question whether the resolution carried by the subscribing 'adherents' there, that this congress had a "caractère vraiment international", was, or was not, rather seriously qualified by the aspiration appended to it "que ce caractère international devienne chaque fois plus effectif" If a congress be already 'vraiment international', it cannot become more so by any enhancement or recurrence, except on the Bellman's principle, "What I tell you three times is true" What all anthropologists desire—and probably many persons who are not—is that in friendly fashion this character of internationality may become not only effective but also accepted

Pioneers of Electrical Progress.

Pioneers of Electrical Communication By Rollo Appleyard Pp ix + 347 (London Macmillan and Co, Ltd, 1930) 21*s* net

THERE can be little doubt that electrical communication has done much to promote international peace It promotes a better mutual understanding between different races and prevents false rumours from spreading and warping the judgment of nations As a help to international commerce it is of the greatest value The manufacture of the necessary electrical apparatus and operating the communication lines provides work for hundreds of thousands of skilled workmen and engineers all over the world Yet it was only in June 1837 that Cooke and Wheatstone patented the first primitive electric telegraph That so little attention has been devoted to the lives of the pioneers who perfected the art is at first sight surprising But when we remember how rapidly epoch making developments have succeeded one another we see how the attention of young engineers has been attracted to the present and the future rather than to the past

In this book, brief and interesting biographies are given of the famous physicists and mathematicians who have laid well and truly the theoretical foundations on which our present systems of communication are based There are many pioneers of electrical communication who have done invaluable work, and so the author has had to choose those whose work he regards as the most fundamental Every electrical engineer and workman is continually using the names ohm, ampere, and volt, yet there are many of them who have forgotten or who never knew that they were called after the great physicists, G S Ohm, A M Ampère, and A Volta There are many more who have only the haziest notions about the personality of these great men, of their environment, and the nature of their life work Mr Appleyard has therefore rightly included them amongst the ten pioneers he has chosen

The author begins by giving an excellent biography of Clerk Maxwell He has taken pains to verify his references and to introduce the right atmosphere into his descriptions Old students will recognise the picture of the lecture room in the Cavendish Laboratory at Cambridge where Maxwell lectured, but in his time there were no modern electric light fittings and switchboards The writer remembers it well in Lord Rayleigh's and J J Thomson's time Maxwell, like Kelvin, was much interested in gyroscopes One of these (p 19) which he showed at Cambridge so far back as 1857 is of the well-known 'diabolo' pattern

Maxwell's electromagnetic theory of light and the great part this theory played in the development of radio telegraphy and telephony is well known Considering the immense amount of highly original work he did, the cutting short of his life at the comparatively early age of forty-eight, when his activities were at their greatest, was an irreparable loss to the scientific world He left to his successors his equations and his theories, which are of inestimable value in scientific work and in telegraphy and radio communication

The story of André Marie Ampère is well related In 1793 his father died on the scaffold, a victim of the 'terreur' The shock of this tragedy produced a complete nervous breakdown of the son, who was then eighteen years old The shadow lasted for more than a year, but his love for mathematics and physics was one of the main factors which effected a cure His great work on the mutual action of two currents, published in 1820, and his wonderful book on electricity and magnetism, published in 1822, led to his election to the professorship of physics in the Collège de France in 1824 He died in 1836 Maxwell well described him as the Newton of electricity, and his name has been universally adopted for the unit of current

Alessandro Volta was born in 1745 and was educated at Como His early leanings were towards literature, but when he was twenty four he was attracted by chemistry and physics He was a man of affairs and a great traveller, visiting Holland, Germany, England, and France, where he met many of the great men of science He married in 1794, and during the next five years wrote many valuable memoirs His home at Como was in the centre of the tempest raging between Austria, France, and Italy at the beginning of last century In 1801, on the invitation of Napoleon, he visited Paris and gave a demonstration before the French Institute Napoleon showered gifts and dignities upon him, making him a comte and senator of the realm of Lombardy He died at the age of eighty two

Georg Simon Ohm belonged to a German burgher family He was born in 1787 and died in 1854 He was an instructor at the Military School in Berlin, then a professor of mathematics at the University of Erlangen, and finally he was appointed in 1849 professor of physics at the University of Munich. His work on electricity was at first neglected, but

the English physicists acknowledged freely their great indebtedness to Ohm

The other biographies given by the author are those of Wheatstone, Hertz, Oersted, Heaviside, Claude Chappe, and Ronalds The book is full of attractive pictures, including portraits of the pioneers, and much of the interesting apparatus used in their researches Visits were made in many cases to the towns where the pioneers dwelt, and photographs taken of the houses in which they lived and of the monuments erected to their memory A R

Nature Unadorned in Tropical Africa

Zwischen Weissem Nil und Belgisch Kongo Von Hugo Adolf Bernatzik Mit Beitragen von Prof Dr Otto Reche, Prof Dr Bernhard Struck und Dr Hellmut Antonius Pp 139+140 Tafeln (Wien L W Seidel und Sohn, 1929) 85s

PROBABLY in no part of the world can picturesque dress and fashion without clothing be studied to better advantage than on the Upper Nile Except perhaps in the Pacific Islands, no people addicted to unabashed nudity are such slaves to fashion as the Shilluks, Dinkas, Nuers, and other Nilotic races The tall Dinka, though possessing not a stitch of clothing, is a proud and haughty individual, and woe betide the Shilluk or Nuer who omits to make room enough for him on the pathway Nothing would induce him to appear in public with a faulty garter below one knee or the wrong shaped spear, and farther south, where bead ornamentation is the order of the day, and beads current money, the traveller may find himself, as the writer has done, in serious difficulties as regards ready cash if, before entering the country, he has omitted to obtain correct information as to the precise sorts of beads to take with him He may buy a choice selection in Houndsditch or in the Birmingham 'trash' markets—green, white, red, or yellow—but when he reaches, say, Northern Kairroudo, he will find that he can do no barter and his camp market soon dwindles No one will part with chickens, goat, eggs, or flour Why? Because the traveller has none of the particular blue beads which he notices are worn by all the men, women, and children of the district His beautiful Brummagem works of art are valueless

To change a fashion is not possible, but one may sometimes initiate a new one, if not in beads, perhaps in something else. Many years ago, when buying a few barter goods for an African expedition, I discovered in an East End cheapjack's shop an opera hat labelled one shilling, and after a little loitering succeeded in purchasing a box of fifty at the price of sixpence each Taking them out to railhead on Lake Victoria, I travelled amongst a tall and naked people, making a judicious present of an opera hat to an occasional chief, snapping it open and shut to the huge delight and curiosity of the intended recipient and his retinue Before a week had gone by the fashion was set Opera hats were the vogue Chiefs and Prime Ministers were as thick as bees as soon as camp was formed Goats, chickens, and everything that could be thought of, were for sale, even ivory One big chief from afar appeared dressed in a lady's very dirty old blue dressing gown, without fastenings and split down the back—the only clothed man in the district How he could have acquired such a possession was difficult to conjecture He brought a small tusk of ivory and wanted a hat in exchange, which he was given After trying the opening and shutting trick to the intense interest of the assembled multitude, which laughed in unison with him, he placed it proudly on a head much too large for its covering It was then the giver's turn to laugh discreetly

The prevailing present day fashions amongst Nilotic tribes may be well studied by a perusal of Dr Hugo Adolf Bernatzik's recent publication Less than a third of this big volume consists of letterpress, the remainder being a series of enlarged and wonderfully reproduced photographs As explained in the foreword, it is the outcome of an expedition decided upon originally for the purpose of taking photographs and films of people and animals in those parts of tropical Africa which are at present little known and difficult to reach He was anxious, the author says, first to visit the hilly country between the Nile and Lake Rudolf, and then to travel westward to the Atlantic through the Belgian Congo, photographing native inhabitants and the animals along the margins of the "mighty Congo forests" He had no success, however, as regards visiting the regions he specially wished to explore After eighteen months' preparation, the expedition duly arrived at Khartoum in January 1927, with a very extensive outfit consisting of 2 cinema cameras each with 5 objectives, 6 cameras, with 2 telephoto lenses and a flashlight apparatus, etc A thousand plates and ten thousand metres of film were also provided, and accompanying the author was Bedrich Machulka, of Prague, as safari leader On reaching Khartoum, great was their disappointment to learn that the regions west of Lake Rudolf were out of bounds, owing to the fact of the turbulent Turkana tribes being still only

partially under administrative control, a well-known fact that should have been ascertained beforehand In the alternative, the expedition travelled by sailing Ghayassa to the limits of the navigable Nile at Redjaf, making short motor-car and porterage trips to the Nuba Mountains, Rumbeck and Meridi in the Bahr-el-Ghazal, and elsewhere

Owing mainly, it would seem, to sleeping sickness regulations and the fear of malaria—for he refers to a series of dangerous tropical diseases—Dr Bernatzik never managed to get far from the river, and did not succeed in taking any animal photographs, or apparently in making any important zoological or ethnological collections, but occupied his time, during one dry season, in the thickly populated regions inhabited by Shilluks and Dinkas, photographing things and people, chiefly scenes depicting village life—dress, occupations, dances, etc His series of 204 magnificent photographs tell their own tale far better than any description could do The letterpress of the book contains little new information regarding the fairly well known life and customs of these tall, nude, cattle tending and peaceful tribes on the Upper Nile

In this attractive picture book, no less disregard of European conventionalities is shown by the photographer, in his endeavour to portray actual conditions faithfully, than is displayed by the Shilluk and his neighbours in their absolute unconsciousness of nudity Being within the local fashion, outward contentment reigns amongst them, though inwardly these people are filled with astonishment at the grotesqueness of the white man's clothing, to them quite unnecessary

Cuthbert Christy

Explosion Researches

Gaseous Combustion at High Pressures being mainly an Account of the Researches carried out in the High Pressure Gas Research Laboratories of the Imperial College of Science and Technology, London, together with the Equipment and Experimental Methods Employed By Prof William A Bone, Dr Dudley M Newitt, and Dr Donald T A Townend Pp xiii + 396 + 14 plates (London, New York and Toronto Longmans, Green and Co , Ltd , 1929) 42*s* net

It was at one time a practice as common as it is commendable for the author or instigator of scientific work that mattered to publish a volume of 'collected researches', wherein were reprinted such of his scattered papers, first published in the journal of one or other scientific society, as the author considered most worthy Prof Bone, to judge from his recent "Flame and Combustion in Gases" and his still more recent "Gaseous Combustion at High Pressures", rightly believes this to have been a helpful practice—helpful perhaps to himself and his students, in enabling a conspectus of work accomplished readily to be made, and helpful undoubtedly to other scientific workers in the same or adjacent fields

"Gaseous Combustion at High Pressures" lacks the fascination of the earlier volume, partly because the subject dealt with is more restricted, and largely because there is so little information from other sources with which to make comparison Organised research on the combustion of gases at high pressures has hitherto been confined to Prof Bone's laboratories No one who has had the privilege of working with Prof Bone, or who has studied carefully the published accounts of his work, can have failed to be impressed by his thoroughness, his attention to detail, and his manifest determination to 'make sure of his facts' There is therefore a predisposition to take the correctness of his observations (if not his interpretation of them) for granted But the new observations are so many, and some of them so surprising, that it is disconcerting to have no check on any of them No doubt one of the objects of the present volume is to encourage others to embark on what is a peculiarly difficult (and potentially dangerous) study It is to be hoped that it will have that result

To those who, to quote the authors, "may be induced to enter the field", the most valuable chapters of the book will be the first seven These describe the apparatus installed at the High-Pressure Gas Research Laboratories at the Imperial College, London, with special emphasis on the precautions necessary to ensure safety in its use The preparation, storage, and compression of gases, the compressibilities of gases and their mixtures , the character of the explosion-vessels and of the filling system, with its valves and gauges , and the pressure gauges used for recording the development of the explosion pressures, are all described with a wealth of detail which should warn anyone who undertakes similar experiments against the pitfalls that the authors themselves have encountered

The experimental results, most of which have been published in either the *Proceedings* or the *Transactions* of the Royal Society, deal with, as one of the principal subjects, the rôle of nitrogen in explosions of carbon monoxide and air, and the

effect of replacing nitrogen by other gases The effect of varying the initial pressure, and of the addition of either hydrogen or steam, on explosions of carbon monoxide and air is also described The significance of the formation of nitric oxide during such explosions is discussed It is made clear that nitrogen is far from being an 'inert' diluent, for "it seems probable that in carbonic oxide — air explosions, nitrogen and carbonic oxide can act 'in resonance', the nitrogen intercepting and absorbing the characteristic radiation emitted by the burning carbonic oxide, thereby acquiring increased internal (vibrational) energy and under such 'excitation' becoming chemically more active than normal nitrogen molecules of the same mean kinetic energy" (p 140)

Explosion experiments are also used to study the effect of initial pressure on the limits of inflammability of gases and to obtain information as to the specific heats and degree of dissociation of gases at high temperatures

It would be idle to attempt to discuss the several controversial matters to which the authors' interpretation of their results is directed, for, as already stated, there is no basis for comparison of the results themselves If it were permissible (and it may be) to argue from the innumerable results of explosions at low pressures, it might be suggested that, since the relationship between time and pressure, given by a time pressure manometer chart, is, unfortunately, influenced by such externals as the characteristics of the pressure gauge, the shape of the explosion vessel and the position of the point of ignition, the interpretation of time-pressure records of low pressure gaseous explosions, and it may be of these high-pressure explosions also, is rendered somewhat uncertain

The book is remarkable as a record of achievement and of triumph over difficulties As such, it should make a wide appeal

R V WHEELER

Our Bookshelf

Repetitorium der allgemeinen Zoologie (Morphologie, Physiologie, Okologie, Abstammungslehre) Von Prof Dr Walter Stempell Pp vi+268 (Berlin Gebruder Borntraeger, 1929) 7 60 gold marks

"REPETITORIUM" inevitably suggests a cram book, and in his preface the author humorously describes how he was brought to write this work especially to help the young student of medicine or of agriculture who wants to 'get up' zoology for his examination in the least possible time But if the published outcome of Prof Stempell's difficult undertaking is any true index of the extent and diversity of the zoological knowledge required from the German student at this stage in his education, then indeed the English universities should look to some revision of their teaching in the elementary grades

The first section deals mainly with morphology, and in spirit it is as far removed from the old fashioned 'type teaching' still favoured by many of our schools as it is from the specialised 'zoology for medical men' in vogue elsewhere There follow admirable sections on physiology, embryology, ecology, and evolutionary theories

The author apologises for the 'mere extract' that is all he can furnish within the limits he has set himself, and he especially directs that it be used as an accompaniment to more detailed works "An extract", he says, "can never be a really well flavoured and meaty soup" But the extract he has so skilfully prepared is far from flavourless, and one must only regret that incapacity to read foreign languages with any ease must debar so many English students from tasting this really sound decoction D L M

Die Tierwelt der Nord und Ostsee Begrundet von G Grimpe und E Wagler Lieferung 14, Teil 10f *Amphipoda* Von K Stephensen Pp 188 (Leipzig Akademische Verlagsgesellschaft m b H, 1929) 15 60 gold marks

DR K STEPHENSEN'S account of the Amphipoda takes an important place in this most useful work Such a specialist in the subject of course understands how to treat it simply and yet fully, and those who use this monograph will find their work made easy for them in many ways With this large group it is impossible to figure every species, but every genus is figured, and usually a part or parts of every species These illustrations are clear and good, and one should be able to identify from them any species in the area Useful keys are supplied beginning with the sub orders and tribes, through families and genera, to species More work than usual is involved in these keys, for in some cases the males and females are so different that they have to be specially separated

The systematic part of the work occupies 148 pages out of the whole 188 The introduction, besides describing the anatomy clearly, gives a very good account of the bionomics of the Amphipoda This is specially interesting, for it touches upon such subjects as intersexes, sexual dimorphism, breeding habits, development, life histories, food and parasites A large amount of space is given to biogeography and the detailed notes on distribution are of great value All students of the group will be grateful for this work

A New School Chemistry By F Sherwood Taylor (Dent's Modern Science Series) Pp viii+508 (London and Toronto J M Dent and Sons, Ltd, 1929) 5s

ALTHOUGH the subject matter of this elementary text book is not new, the author's presentation of it is clear and attractive, the chapters being divided into descriptive text, practical exercises,

and examination questions Short summaries and experiments for demonstration are sometimes appended, and the time required for each exercise is also given This should be very helpful to the teacher in organising his practical classes In the section on chemical theory, the combination of the two equations representing the effects of pressure and temperature on the volume of a gas (p 137) may cause some difficulty, and the reason for introducing the idea of 'molecules' is not quite clear, otherwise the reasoning which leads up to the determination of atomic weights seems to have been admirably condensed

The chapter on double decomposition opens well with the statement that acids, alkalis, and salts are all polar compounds, and a hint is given that two types of union may be involved in compounds like copper sulphate and that these two types are due to the sharing of electrons and to electrical attraction respectively Nevertheless, the chapter on valency is disappointing, no attempt being made to use the terms electrovalence and covalence Electrolysis and qualitative analysis are also dealt with in an elementary way, but the ionic hypothesis is not used In the chapter on acidimetry the advantage of calculating the normalities of solutions is clearly explained

Haliotis By Doris R Crofts (Liverpool Marine Biology Committee L M B C Memoirs on Typical British Marine Plants and Animals, 29) Pp viii + 174 + 8 plates (Liverpool University Press of Liverpool, London Hodder and Stoughton, Ltd, 1929) 10*s* 6*d*

The L M B C Memoirs are indispensable 'apparatus' in all zoological laboratories, and especially is this true of the little monographs on the Mollusca All teachers know the difficulty of describing to a class the intricate peculiarities of molluscan structure, and it is not until the student sits down with scalpel and forceps to unravel for himself the intertwisted parts that he begins to appreciate their relations

Miss Crofts' volume on *Haliotis* is a valuable addition to the series, for this animal is "the only primitive British gastropod which is large enough for satisfactory dissection", and its general anatomy has never before been given completely by any one author Clear directions for dissection are set forth, and, in addition to the plates, there are many text figures that help to elucidate puzzling features in the anatomy There are some interesting new bionomical notes, and the author strongly recommends the formation of permanent reservation areas off Guernsey to make good the serious depletion of the crop of 'ormers' that two years' suspension of the fishery there has only partially stayed D L M

Practical Criticism a Study of Literary Judgment By I A Richards Pp xiii + 375 (London Kegan Paul and Co, Ltd, 1929) 12*s* 6*d* net

This book has attracted much attention in literary circles, but it deserves notice here also, because it is a good example of the present tendency to bridge the old gulf between the study of the humanities and the study of science Mr Richards points out that there are subjects which can be discussed in terms of verifiable facts and precise hypotheses These are the subjects called the sciences There are other subjects, such as the concrete affairs of organisation and administration, which can be handled by rules of thumb and accepted conventions Between these two come ethics, metaphysics, theology, æsthetics, and so forth, the sphere of "random beliefs and hopeful guesses"

Mr Richards takes one of these fields of warm disputation, that of literary criticism, and makes it the subject of as scientific an inquiry as the nature of the case permits By an interesting expedient, devised in the course of teaching duties, he got a large number of people, similar as to age and general culture, to pass unbiased judgments upon certain selected poems of unrevealed authorship The results seem to have surprised even Mr Richards, for the same poem was described in terms ranging between "this is a fine poem" and "this is absolute tripe" Here, then, is the problem Can nothing be done to improve the technique of criticism? The familiar watchwords of the great critics do not help much, because they are only pointers which may lead different minds to widely different conclusions Mr Richards ends his fascinating inquiry by a warning against the abuse of psychology, and some suggestions towards clearing away the fogs of criticism The better teaching of English is, he thinks, the chief hope

A Countryman's Day Book an Anthology of Countryside Lore Compiled and arranged by C N French Pp xxvi + 254 (London and Toronto J M Dent and Sons, Ltd, 1929) 6*s* net

This collection of weather 'saws' and countryside lore will interest and amuse many people of very varied interests Meteorologists, farmers, gardeners, and many others will find in the quotations from old anthologies and in the popular sayings a modicum of truth, but such a preponderance of error as to cause wonder regarding the origin of most of these popular beliefs of bygone times As the title indicates, a set of 'saws' and quotations is given for each day of the year The book is dedicated to cottage gardeners, and contains a number of quaint illustrations copied from ancient sources

La vie du globe et la science moderne Par Prof L Houllevigue Pp xi + 244 (Paris Armand Colin, 1929) 14 francs

In a number of short essays, the author of this little volume has succeeded in giving a general account of modern ideas bearing on the physics of the globe There is no attempt at detailed treatment, for the book is written for the general reader and not the specialist, but Prof Houllevigue has chosen his matter well and has a faculty of lucid exposition without the waste of words His book should prove of interest to workers in other branches of science who care to know the trend of thought in terrestrial physics

Letters to the Editor

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

Spectrum of the Sunlit Auroral Rays

IN a letter in NATURE of Dec 21, 1929, Prof Vegard criticised some researches which Moxnes and I had published in the issue of Aug 17, 1929 In my letter I pointed out that the results obtained were only preliminary, and that the measurements of the

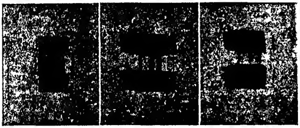

FIG 1 —Spectrum of sunlit auroral rays (*B*) as compared with spectra of ordinary aurora in the earth s shadow (*A*) and (*C*) Plates *Sonia EW*

intensities of the spectral lines were to be considered not as quantitative measurements, but only as qualitative indications of relative strength

Hoping to get more spectra of sunlit auroral rays last autumn, we made an arrangement to obtain spectra of sunlit and non sunlit auroral rays *on the*

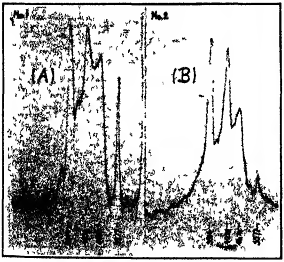

FIG 2 —Photometric registrations of the spectra (*A*) and (*B*) made by Moxnes

same plate—but no sunlit aurora rays were observed We only obtained a spectrum of an ordinary aurora in the earth's shadow, but this spectrum is very interesting as compared with the spectrum already published of the sunlit auroral rays of Mar 15–16 in so far as the aurora line 5577 A has about the same strength on both plates The nitrogen lines 3914 A and 4278 A, however, are very much stronger on the plate of Mar 15–16

As the reproduced figure of the spectra in my letter published on Aug 17, 1929, was not very convincing, I have had a better one made, where the spectra are reproduced direct from the plates This is seen in Fig 1, where *A* is the spectrum of the ordinary aurora of Mar 15–16 in the earth's shadow, *B* the spectrum of the sunlit auroral rays of the same

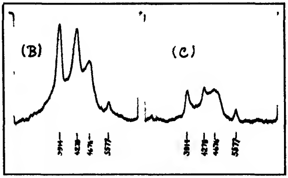

FIG 3 —Photometric registrations of the spectra (*B*) and (*C*) made by Moxnes

night, and *C* the spectrum of ordinary non-sunlit aurora from last autumn

The auroral spectra are in the middle between comparison spectra of helium and the auroral line 5577 A is to the right, the nitrogen lines to the left

In Fig 2 are shown the photometric registrations of the spectra *A* and *B* made by Moxnes already published in my letter of Aug 17, 1929 As Fig 3 we reproduce new registrams made by Moxnes of the spectra *B* and *C*, and from these our previous conclusions seem to be considerably strengthened

The Photo-electric Recording of Daylight

AT the Conference of Empire Meteorologists in London last August we exhibited apparatus intended for use in the photo electric recording of daylight This has now been placed in position, the photometer being on the parapet of the flat roof of the Marine Biological Laboratory at Plymouth and the recorder in the laboratory

The photometer contains a Burt vacuum sodium photo electric cell mounted in a heavy gun metal case, designed primarily for use in measuring submarine illumination There is a stout glass window, above which is a sheet of double surface flashed opal glass This acts as an efficient diffusing surface and is set horizontally so as to measure vertical illumination From the photometer case two rubber insulated high tension ignition cables, each 100 yards long, lead to the laboratory on the ground floor, being passed through cork discs—such as are used as floats for nets—to protect them from chafing They are there connected to a 60 volt ' Exide ' storage battery (five 10 v type WJ plus one 10 v type WJG) and to a Cambridge Instrument Co 'thread recorder' The accumulators maintain a steady 60 volt pressure as the photo electric current is very small, and the batteries are mounted on paraffin wax

The recorder has a scale with fifty divisions, corresponding in all to 5 micro amperes, which happens to be close to the maximum current given by this particular photometer used in mid winter noon sunlight For more intense light the current is shunted to one-half or to one fifth

The sodium cell is sensitive mainly to blue light,

but gives a good idea of the fluctuations in daylight One of the General Electric Co's new red-sensitive cells might be used instead, as it is sensitive throughout the visible spectrum, and gives a suitable current Its infra red sensitivity would, however, constitute a drawback

The smooth graph marked A on the accompanying figure shows the record obtained for Dec 19, starting from 10 A M The recorder gives one dot per minute, but where the light was changing in a regular manner dots have been omitted in the figure The sunshine recorder about 100 yards away showed 7 hr 0 min for Dec 19, the sky was cloudless with a moderate south-south east breeze The irregular graph shows the variations in light for the whole of Dec 20, which was a dry day with a south west wind of 10-15 m p h The sunshine record was zero, but the sun nearly broke through at 11 40 A M, and the vertical illumination then exceeded that of Dec 19 with clear sun The cross at noon denotes the dot obtained on Dec 19 by shading the photometer from the direct rays of the sun and is a measure of the diffuse light The ratio of total vertical to vertical diffuse light was thus found to be 1 49 At noon in midsummer this ratio, β, measured in the same position with a similar and similarly mounted sodium cell was, as a maximum, 4 28, a more usual value being about 3 3

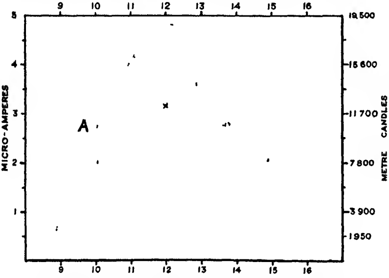

FIG 1 —The regular curve shows the vertical illumination for Dec 19 1929, starting from 10 A M, marked A The irregular curve is the record for Dec 20 For cross see text The left hand ordinates are micro amperes, the right hand are metre candles, while the abscissæ are hours The charts are marked in quarter hours and tenths of a micro ampere

The ordinates on the right hand side of the figure show metre candles, the photometer having been standardised against an open carbon arc—selected as being the source most nearly akin to daylight and easily reproducible

We hope by means of these records to be able to correlate plant growth with daily illumination in metre-candle hours The cost of the thread recorder was defrayed by the Government Grant Committee of the Royal Society

The 'Wave Band' Theory of Wireless Transmission

Two obvious objections can be made to Sir Ambrose Fleming's lucid analysis of the wave band theory in NATURE of Jan 18

The first is theoretical To deny the reality of the wave band method of regarding a modulated carrier wave is at bottom much the same as to deny that a point on the rim of a rolling bicycle wheel 'hops along' in a series of cycloids In both examples the two alternative points of view have equal rights to the name 'real'

The second is practical, and so may justify this letter Two stations operating on frequencies, say, of 500 and 520 kilocycles, will not give a noticeable heterodyne note, as their beat frequency of 10,000 is too high for the average loud speaker to reproduce effectively But if one of them modulates its carrier wave by a soprano solo, bad heterodyning results every time the soprano emits a high note The fluctuating amplitude formulation does not lead us to expect this off hand, the wave band formulation does In practice, therefore, the latter is likely to hold its own

E H LINFOOT

Graduate College,
Princeton University,
New Jersey, Feb 2

SIR AMBROSE FLEMING does not give us in his very able article any alternative explanation of the fundamental problem of the tuned circuit, namely, that the really selective circuit *does* cut off the higher audio frequencies, generally explained by the 'cutting of the side bands' What is actually happening? Does not the solution lie in the fact that the damping of a resonant system falls off as its selectivity increases? In our modern lightly damped receiver, the oscillation persists long after its excitation has ceased If it is excited by a carrier modulated by a high audio frequency, the persistence of its vibrations will not allow the amplitude of these to vary with the modulated amplitude of the incoming wave and the modulation gets flattened out, whilst with a low modulating frequency, or bass note, the slower rise and fall of the carrier amplitude gives time for the circuit oscillations to rise and fall with it and thus give a faithful reproduction

So the lightly damped circuit gives a gradual falling off in intensity as we go up the scale of audio frequencies, the lighter the damping the earlier this becomes noticeable, until in the limit all audio frequencies would be 'cut off' as the 'side band' theory has it Either theory explains this, the cause of all the trouble in the ether, but, whereas the latter suggests that the defect is inherent however real selectivity is attained—that is, response only to the carrier vicinity—the former suggests that if some other means of selectivity than the lightly damped circuit could be found—even with response to the carrier alone—there is no reason why the modulation should not be faithfully reproduced The 'side band' theory puts the onus on the wave itself, the amplitude idea on the receiver, the former closes and bolts the door, while the latter leaves it open for exploration

and fresh ideas It does not then seem to be "merely a matter of a choice of points of view", as Prof Fortescue suggests

Sir Ambrose states that we do not have to alter the tuning of our condensers to receive high notes Now it is an experimental fact that if we have a receiver of several stages—say three tuned circuits, each lightly damped—the high notes will be cut down very effectively, but we can restore them by tuning one circuit to the carrier and the other two slightly above and below respectively This at first sight suggests that the side bands exist and tuning to them restores the high notes However, it admits of as good an explanation on the other theory, for it is observed that the effect of 'detuning' thus is to reduce the overall damping of the circuits—as evidenced by a reduction in intensity and a drop in the maximum amplitude—while the resonance curve becomes a steeper sided one with more flattened top Thus more selectivity is achieved without loss of damping by three detuned circuits

A A NEWBOLD

Evesham, Feb 13

ALTHOUGH the letters recently published in NATURE on the above theory have indicated that some of the contentions in my article of Jan 18 last are not generally supported by scientific opinion, yet some service has perhaps been done by it if only in eliciting the interesting letters from Sir Oliver Lodge, Sir Richard Glazebrook, Prof Fortescue, Mr Bedford, and others

In addition to noting the importance of the remarks by Sir Oliver Lodge, I find the letter of Sir Richard Glazebrook very valuable, because he gives the proof that a receiver tuned to frequencies of $n+m$ or $n-m$ can be set in oscillation by a carrier wave of frequency n modulated by an acoustic frequency m Now here we touch the very pith of the discussion When a carrier wave modulated as above is sent out from a transmitter, can we say it travels through the space to the receiver as two distinct waves of frequencies $n+m$ and $n-m$ respectively? Or is it simply a single modulated wave which can actuate a receiver tuned to the two or more frequencies?

Since we can only detect any wave by a receiver, we have the same difficulty that we have in deciding the nature of a ray of white light and how it is the prism resolves it into an infinity of rays of various wave length in the spectrum That the prism itself has a good deal to do with the effect is indicated by the phenomenon of anomalous dispersion

So it is also with the wireless receiver We have difficulty in disentangling the pure space phenomena from those produced by the receiver itself I am unable to see that those who object to my views on the wave band theory have given proof that the side waves exist in space and are not an effect due to the nature and operation of the receiver

Apart, however, from philosophical questions on which differences of opinion may exist, there is the very practical question What kind of receiver should anyone buy to obtain the best results in receiving broadcast music? An eminent scientific friend tells me in a letter that a wireless dealer told him he ought not to have a very selective receiver to get the best results Prof Fortescue seems to agree to some extent with this statement On the other hand, my experience is that the most selective receiver gives the best results, and many would agree It is, then, very important to ascertain whether good musicians with normal hearing, using highly selective receivers and listening to music of a wide range of pitch detect any enfeeblement of high notes relatively to low notes and if this effect is absent in not very selective receivers I hope some evidence on this point may be gathered in

In the present state of jam in the ether with wave lengths between 200 metres and 600 metres the wireless receiver makers require some guidance from scientific opinion as to the type of receiver they should make and advise their customers to buy The reception from 5GB, 2LO, and the Brookman's Park short wave, of broadcast music in anything like satisfactory tone is becoming very difficult and demands some remedy Is that remedy to be found in the use of hyperselective receivers or not? That is the question, and the answer to it given by experiment bears closely on the validity of the wave band theory

Crossed Connexion of the Cerebral Hemispheres with the Muscles and Sense Organs

PROF ROAF'S interesting speculation published under the above title in NATURE of Feb 8, (p 203) is based on the assumption that the two eyes possessed by most vertebrate animals have arisen in the course of evolution from a single median eye such as is found in the free swimming larva of an Ascidian He argues (if I understand him rightly) that when the image of an object falls on the left half of the retina of an animal of this type, the appropriate response is a contraction of the muscles of the right side of the creature's body and tail, and that the efferent nerve paths from the brain will therefore be simplified if the afferent fibres involved end in the right half of the central nervous system Such a view may be held to account for the central projection of the retina of each of the two eyes of a mammal in such a way that fibres from its upper half are connected with the superior lip of the calcarine fissure, and that fibres from its right margin are connected with cerebral points situated to the left of those with which areas of retina lying farther to the left are connected (This may legitimately be inferred from the work of Gordon Holmes and others on cortical projection in man) But Prof Roaf goes further and suggests that it may also account for the fact that in most vertebrates the right eye is directly connected only with the left side of the brain, and the paths from the two eyes undergo complete decussation At this point the argument seems to me to become less convincing

Even if comparative anatomists were to assure us that a single median eye was indeed the direct ancestor of our two eyes (and, so far as I am aware, such an ancestry has not previously been suggested), we should need also to be told that the evolutionary development took the form of a bisection of this eye so that the right half of its retina became the retina of the resulting right eye Alternatively we should have to assume that, in the most primitive vertebrates possessing two eyes, the left eye received images of objects lying to the right of those seen by the right eye

Now it is usual in all vertebrates, other than a few birds and higher mammals, to find the two eyes placed laterally in the head, with the right eye forming images only of objects situated on the animal's right, and with little overlap between the two visual fields Impulses from the right eye are carried to the left side of the brain, and are then relayed back to the right side in order (presumably) that contraction of muscles on this side of the animal's body may direct its movements towards the seen object If Prof Roaf accepts the rather improbable suggestions contained in the last paragraph as an explanation of the

sensory decussation, I imagine he would say that this further development of laterally placed eyes necessitated the motor decussations

Surely, however, this double decussation is an incredibly clumsy arrangement if he is right in suggesting that "By repeated correlation between stimulation due to an object and the movement to bring the image of it on the centre of the retina, a relationship [can] be established in the same way that a conditioned reflex is developed" A much simpler arrangement, and one which would avoid the double decussation, would be that found in certain cephalopods, where each eye is connected with its own side of the brain Moreover, if the fabric of the central nervous system is as plastic in the hands of evolution as Prof Roaf postulates, would it not be more probable that, early in the development of two laterally placed eyes from a single median eye, the previously crossed optic paths should become uncrossed, rather than that the whole motor system should be reshuffled and new crossed motor paths added?

Arguments like mine, based on human estimates of the unerring wisdom of providence or Nature, are notoriously fallacious, but unless some evidence is forthcoming in support of the evolutionary history outlined in my second paragraph, I find it difficult to take Prof Roaf's suggestion seriously Certainly the "crossed relationship is suggestive of an optical effect", but until more assistance is obtained from comparative anatomy the problem cannot be satisfactorily solved Ramón y Cajal's theory (1898) was also inspired by optical projection, and all that he could say in its favour in 1911 was that it "n'a pu être remplacée par un autre qui fût aussi plausible" ("Histologie du Système nerveux" Paris, II p 380) Modern knowledge of cortical projection from the retina seems to negative the fundamental assumption on which his psycho anatomical view was based Sensori-motor relations like those postulated by Prof Roaf would seem to offer a more hopeful clue (cf Sherrington, "The Integrative Action of the Nervous System", London, 1906, pp 384-386), and I hope that the question will not be allowed to drop

Stellar Absorption Lines

Considerable attention has been recently devoted by various investigators to the explanation of the observed contours of stellar absorption lines There are many physical factors that contribute to the formation of the contour The most important are: (1) the abundance of the absorbing atoms in the gas, (2) the Stark effect, and (3) Doppler effects due to the rotation of the stars. We are here concerned with the first of these, which is usually designated as 'natural widening' of spectral lines H N Russell and others have shown that this type of broadening is particularly important in the stars because of the large number of absorbing atoms present in a stellar reversing layer. It is responsible for the enormous widths of the H and K lines of Ca^+ in the later spectral types

The 'natural widening' of spectral lines has been exhaustively studied by physicists The scattering coefficient can be expressed by

$$\sigma = c\,\frac{N\,f}{(\lambda - \lambda_0)^2},$$

where c depends upon atomic constants only, N is the number of absorbing atoms per cm^3, and f is the 'oscillator strength' According to Unsöld, the contour of a stellar absorption line is then given by

$$\frac{I}{I_0} = \frac{1}{1 + \sigma\ H},$$

where I is the intensity in the line, I_0 is the intensity of the continuous spectrum, and H is the thickness of the absorbing layer Near the centre of the line the intensity should be vanishingly small While his

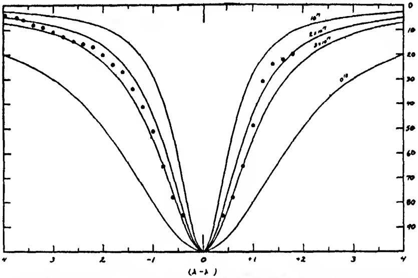

Fig 1—The contour of $H\beta$ in the spectrum of 7 ε Aurigæ the ordinates being percentages of absorption of the continuous spectrum, and the abscissæ Ångström units The dots are the mean observations from five spectrograms, and the curves are theoretical contours given by Unsöld's formula, the figures representing the values of NHf

expression for the scattering coefficient is not strictly applicable to the centre of the line itself, Unsöld has pointed out that in practice all absorption lines in which natural widening is paramount should be black in the centre That the theory is correct has been shown by R Minkowski (*Zeits für Physik*, 36, 839; 1926), who found that lines produced in the laboratory actually appear black in the centre

In the stars, on the other hand, the absorption lines do not, as a rule, appear black Even the broad calcium lines H and K show appreciable residual intensities It has been believed by many that a stellar line is never black in the centre and that the observed contour is thus in disagreement with Unsöld's theory

Our observations show that stellar absorption lines do occasionally appear black in the centre In the accompanying diagram (Fig 1) we have reproduced the contour of the $H\beta$ line in ε Aurigæ It will be seen that the observations agree very well with Unsöld's curve for $NHf = 2\ 5 \times 10^{17}$ The middle of the line is perfectly transparent on our negatives: there is no trace of residual intensity even on our longest exposures Extrapolation of the observations toward the centre would bring the residual intensity to zero, in full agreement with the theory

ϵ Aurigæ is known to be a supergiant star. Its atmospheric density must consequently be very low. This seems to support the idea, expressed first by Unsöld, that the observed residual intensities in the lines of other stars are due to some process depending upon collisions between the atoms. The fact that the hydrogen line in ϵ Aurigæ is free from the wide wings which are characteristic for other stars and are apparently produced by intra-molecular Stark effect, is itself a good indication that the pressure is very low.

Zygospore Formation in Mucors

SINCE the discovery of heterothallism, or separate sexes, in Mucors by Blakeslee some twenty-five years ago, the conception has been widely extended in the fungi and has recently been applied to the green algæ. But in recent years the facts regarding multiple sexes in fungi have become so complex as to strain credulity, and new views, such as Dame Helen Gwynne-Vaughan's conception of nutritive heterothallism, have been coming in to relieve the tension on the earlier rigid hypothesis of fixed + and − strains corresponding respectively to the female and the male sex.

Finding peculiar results from certain strains of *Mucor hiemalis* which we have had for some years in this laboratory, it was decided to make an analytical study of the process of zygospore formation in this species in relation to various media. Several other genera of Mucorineæ have also been investigated at the same time. Subcultures were made from the original stocks, and subsequent monospore cultures from these. Experiments were made, not only varying the environmental conditions such as temperature, humidity, and light, but also to show the effects of adding various substances to the agar culture medium. A few only of these experiments can be summarised here.

In the heterothallic *Mucor hiemalis*, zygospore formation is most favoured when the moisture content of the medium is at a minimum, and the humidity can be regulated by varying the percentage of agar used in making up the medium. The addition of zinc nitrate, on the contrary, appears to increase the development of mycelium and sporangia. Most of the species thrive best on an alkaline medium (pH 7·2). When + and − strains of *Mucor hiemalis* are grown together in a Petrie dish on potato agar at a temperature of about 15° C., zygospore formation appears to be completely inhibited; but identical cultures grown at 25° C. produce large numbers of zygospores. At low temperature also the two strains will not intermingle, but a line of repulsion or aversion remains between them, which appears to be due to the fact that the medium has been rendered toxic. When such cultures are placed in an incubator at higher temperature they produce zygospores.

Small doses of oxalic, formic, malic, citric, or hydrochloric acids added to the medium so as to change the pH from 7·2 to 6·8 have a toxic effect on the fungus, causing repulsion in every case; that is, with + and +, or − and −, or + and −. However, like strains grown on a medium containing starch (2 per cent), agar (1·5 per cent), and diastase (0·04 per cent) will show no signs of repulsion, but no zygospores are formed except between + and − strains. Different media produce striking effects on the morphological characters of the mycelium. Media having sugars or traces of acids produce enormous oil inclusions in the hyphæ, which are cylindrical, thick, and heavy in appearance, while on a medium without sugar or acid the hyphæ are flat, hyaline, and much less branched. In starch diastase medium the hyphæ become septate and the protoplasm highly granular.

It is found that the mycelia of + and − *Mucor*, *Rhizopus*, *Sporodinia*, and other Mucorineæ all produce two kinds of sporangia, namely, large and small, the large sporangia emitting large spores and the small sporangia small ones.

Perhaps the most striking result has been the production of imperfect zygospores from the − strain of *M. hiemalis* alone when grown on a medium composed of 1 per cent fructose, 1·2 per cent agar and a few drops of acetic acid bringing the pH to 6·8. These zygospores ceased development after fusion of the progametes had taken place, and the wall had begun to thicken. The process resembles the 'imperfect hybridisation' obtained by Blakeslee by bringing together + and − strains from different genera. In no case has zygospore formation been obtained between + strains. Chlamydospores are frequently produced in all the strains, and under certain conditions azygospores are formed.

By fixing the mycelium in 3·5 per cent formalin and staining in Ehrlich's hæmatoxylin, the nuclei in zygospore formation can be followed under an immersion lens. The pronuclei remain separate, although in close contact, so far as their history has yet been followed. Several zygospores have been germinated in hanging drop cultures by a method to be described later, and it is hoped to follow the later history of the nuclei.

This work is being extended in various directions and a full account will be published later.

The Viscosity of Liquids

THE viscosity of liquids is a subject which, so far as I know, has hitherto been without any general theoretical basis. No physical mechanism, for example, has ever been brought forward to account even for so simple and general a fact as the decrease of liquid viscosity with temperature, in contrast to the familiar and well explained increase of gaseous viscosity with temperature. As a result, the study has hitherto consisted largely of a collection of more or less well established empirical relations, mostly of limited scope.

In consequence of certain general theoretical considerations, shortly to be published, which I have been applying to the problem of liquid viscosity, I have not only been able to give a general account of the influence of temperature on liquid viscosity, but also I have arrived at a formula of great simplicity which fits the experimental facts very well. There is, of course, a whole collection of empirical formulæ (due to Poiseuille, Koch, Meyer, Slotte, and others—see, for example, Hatschek's "The Viscosity of Liquids" (1928)) connecting viscosity with temperature, but they have all at least three arbitrary constants, and a very limited range of validity. Different types of formula have been employed for different liquids. My formula has only two constants, so that the agreement between it and the experiment emboldens me to believe that it has some fundamental significance, as indicated by my theory. The formula is

$$\eta = Ae^{b/T}$$

where η is the viscosity, T the absolute temperature, and A and b the constants. It holds over practically

the whole temperature range with a great variety of substances The following are two examples, chosen not because of exceptional agreement, but because of the wide range of temperature and viscosity which they cover

Temp	Butyl Alcohol		Octane	
	η_{calc}	η_{obs}	η_{calc}	η_{obs}
0° C	0 0523	0 0519	0 00706	0 00706
10	0 0388	0 0387	0 00616	0 00616
20	0 0293	0 0295	0 00543	0 00542
30	0 0226	0 0227	0 00482	0 00483
40	0 0177	0 0178	0 00432	0 00433
50	0 0141	0 0141	0 00390	0 00391
60	0 01135	0 01139	0 00354	0 00355
70	0 00926	0 00929	0 00323	0 00324
80	0 00765	0 00766	0 00296	0 00297
90	0 00638	0 00638	0 00273	0 00273
100	0 00538	0 00539	0 00252	0 00252
110	0 00458	0 00460	0 00234	0 00234
120			0 00219	0 00216

η_{obs} is taken from Landolt Börnstein It is doubtful if the experimental error is less than the very slight divergence between calculation and experiment

The only general viscosity relation which I have found to provide a test for the formula is one due to A W Porter This empirical relation is as follows If two liquids be examined throughout a sufficient range of temperature, a number of temperatures T_1 can generally be found for one liquid I, at which the viscosity is the same as it is for the other liquid II at a number of temperatures T_2 If T_1/T_2 is plotted against T_1 a straight line results This relation follows at once from the formula given above For if A_1, b_1 and A_2, b_2 are the constants for liquids I and II, then

$$A_1 e^{b_1/T_1} = A_2 e^{b_2/T_2}$$

$$\log A_1/A_2 = \text{constant for the two liquids concerned} = b_2/T_2 - b_1/T_1$$

$$\text{or} \quad T_1/T_2 = \alpha + \beta T_1$$

where α and β are constants, which is the experimental relation

Water, as would be expected, and other associating liquids, demand a further constant for complete representation, but the application of the formula in the region within which it is valid, namely at high temperature, has led to interesting results, to be detailed in a forthcoming publication

Botanical Nomenclature

THE letter from Mr R A Inglis in NATURE of Feb 8, p 204, calls for a reply, and the following is sent on behalf of the British Sub Committee on Nomenclature, which has since 1923 been engaged in examining proposals for the revision of the International Rules of Botanical Nomenclature Mr Inglis is mistaken in supposing that Art 57 is concerned with anything other than spelling The only Article which bears, even indirectly, on gender is Article 7, which states—albeit erroneously—that "Scientific names are in Latin for all groups" It follows that they are subject to the rules of Latin grammar, and that adjectival specific epithets necessarily agree in gender with the generic names to which they are attached The only problem is the correct gender of certain generic names The real difficulty lies in the fact that Latin as used in botany has changed *continuously* from classical times down to the present, and that the same name, for example, *Atriplex*, may have had more than one gender even in ancient Rome It seemed to the Sub Committee that an Article dealing specifically with the gender of generic names was required, and the following new Article has been submitted by them, along with other proposals, for the consideration of the International Botanical Congress (1930)

"The gender of generic names is governed by the following regulations

"I A Greek or Latin word adopted as a generic name normally retains its classical or medieval gender, even if the author who published it gave it a different gender Where, however, the classical or medieval gender varies, or is in dispute, or where it differs from the gender usually ascribed to the generic name, the gender of the latter shall be fixed by the Advisory Committee

"II Generic names which are modern compounds formed from two or more Greek or Latin words take the gender of the last If the termination is altered, however, the gender will follow it

"III Arbitrarily formed generic names, or vernacular names used as generic names, take the gender assigned to them by their authors Where the original author has failed to indicate the gender, the next subsequent author has the right of choice "

Under II, *Atrosperma* is neuter, as urged by Mr Inglis, but *Polygala*, being feminine to Pliny as well as to Linnæus, should, we think, remain feminine (under I)

(Convener, British Sub Committee on Nomenclature)

Royal Botanic Gardens,
Kew, Feb 14

Research and the State

I HAVE read with great interest in NATURE of Nov 23, 1929, Sir Walter Fletcher's lecture on medical research and on the inadequate rewards for such essential activities There are apparently three kinds of activities to be considered

1 The research worker who, if he is one of the best type, has the spirit of inquiry in him He is often quite indifferent to practical results Such people are not too numerous and should be given a free hand

2 The educated publicity agent who makes knowledge available The late Prof Huxley probably represented the greatest man of this type the world has seen

3 The practitioners who adapt their methods to the knowledge gained

All these groups seem to me to be equally important from the social point of view

In common with many associates I regard research conducted by permanent officials as apt to become relatively sterile Skeleton organisations and institutions for research are a necessity The ideal, however, is surely to have a fund available, and when a research worker presents a proposal really worth investigating he can be treated generously until the work is finished

Research as a profession will, I am afraid, tend to end in mediocrity and useful compilations. I am writing, however, chiefly to ask Sir Walter Fletcher how he proposes to influence the public, which, after all, find the money It is certain that the Anglo-Saxon will not act until he understands the objective It is no use presenting to him pages of mathematical formulæ and the like, interesting and useful as they are to a limited circle

In some of the American universities an official editor makes it his business to let each part of the university know what the other departments are doing, and to let all the citizens of the State obtain the

available knowledge which is furnished in clear and simple terms The University of Melbourne is con templating something of the kind at present

To me, systematic popular education is requisite if the ideals voiced by Sir Walter Fletcher are to be translated into practical action Perhaps the end can be achieved in some other way, but ultimately the public spirited citizen and the elector must be pleas antly instructed in the necessity for adequate support Lecturing him for his neglect will not advance matters

JAMES W BARRETT

Melbourne, C 1, Jan 2

Homogeneous Catalysis of Gaseous Reactions

A SHORT time ago it was shown that the decomposi tion of di isopropyl ether in the gaseous state is sub ject to a remarkable catalytic influence of iodine The course of this reaction, which is homogeneous, and quite distinct from that of the uncatalysed re action taking place at higher temperatures, can be represented by the equation

$$\begin{matrix} CH_3 \\ CH_3 \end{matrix}\!\!>\!CH-O-CH\!<\!\!\begin{matrix} CH_3 \\ CH_3 \end{matrix} = \begin{matrix} CH_3 \\ CH_3 \end{matrix}\!\!>\!CO + CH_2\!<\!\!\begin{matrix} CH_3 \\ CH_3 \end{matrix}$$

We now find (*a*) That the same reaction takes place under the catalytic influence not only of iodine, but also of various alkyl iodides and, to a smaller extent, of bromides (*iso*PrI, EtI, MeI, *iso*PrBr, EtBr, $C_2H_4Br_2$, HBr), chlorides have little influence, (*b*) that this catalytic mechanism, involving the transfer of a hydrogen atom within the molecule, is a general one Thus the changes

$$CH_3\ \underset{\substack{|\\ H}}{CH}\ O-CH_2CH_3 = CH_3CHO + C_2H_6$$

and

$$CH_3\ CHO = CH_4 + CO$$

both occur readily in this way

The decomposition of ethyl ether is quite different from the normal homogeneous decomposition (con ditioned by the collision of two ether molecules)

It is to be noted that the hydrogen atom, the trans fer of which is catalysed, is in each case attached to the carbon atom adjacent to the oxygen

Kinetic studies of these and similar reactions are being published shortly

It is interesting to note that this phenomenon, where the hydrogen atom is loosened and transferred under the influence of an electronegative atom, is in a sense complementary to the fundamental process of acid and basic catalysis in solution, which according to Brönsted always involves the giving or accepting of a proton by the catalyst

Do Glass Tubes or Rods Bend under their own Weight?

ABOUT seven years ago, in discussion with some scientific friends, I heard the opinion expressed that glass tubes if stored upright tend to bend permanently under their own weight The same idea is to be found in print Thus, in Ostwald's "Physico-Chemical Measurements" (English Translation, 1894, p 66), we read that glass tubing "must be kept lying flat, otherwise it will become permanently curved"

It seems difficult to reconcile this with the known fact that the annealing temperature of soft glass is somewhere about 500° C , but it was thought worth while to test the point directly A glass rod 4 9 mm in diameter was laid across two nails about 1 metre apart on a brick wall, and loaded at the middle with 300 grams, which was judged to be near the limit of what it would safely bear (In fact, after the experiment was concluded, it broke under test at 1060 grams) The height of the mid point was read on a mirror glass scale , the initial loading produced a depression of 2 8 cm After that, for seven years there was no further movement large enough to be considered significant Slight changes of reading were observed from time to time, but they were not systematic, and probably due to internal movements in the wall The final reading was 1 millimetre lower than the initial one If we have regard to the last four years alone, the net change of reading has been too small to measure

The stress applied in this experiment is very great compared with any that can be caused by the weight of the rod itself It is therefore quite certain that glass of mature age does not bend in the way suspected It is perhaps just possible that newly drawn glass may do so

"Encyclopædia Britannica"

THE version of the article 'Tides" in the 14th edition of the 'Encyclopædia Britannica", to which Prof Proudman refers in his letter published in NATURE of Feb 15, has appeared only in five per cent of the sets we expect to distribute That it appeared at all was due solely to an accident at the printers, which we much regret

The publishers have spared neither trouble nor expense to satisfy their distinguished contributor over this article , many thousands of sheets containing the first version have been destroyed, and new pages con taining the revised article printed to replace them

Moreover, in fairness to our subscribers, we think it should be added that Prof Proudman has conceded to two of our representatives that there is no error or misstatement of fact in the first version of the article, and has founded his objection to it on the ground that space was not given for a fuller elaboration of his views

The Classification of the Primates

IN his letter on "The Classification of the Primates" in NATURE of Jan 25, Dr Tate Regan twice refers to "the Mascarene Lemurs" The term "Mascarene" is usually restricted to the Islands of Bourbon, Mauritius, and Rodrigues, of which the first two were discovered by Mascarenhas at the beginning of the sixteenth century Is there any authority for extend ing it, as Dr Tate Regan does, to Madagascar?

The direct evolution of the Platyrrhines from a Lemuroid ancestor, independently of the Catarrhines, was suggested by W D Matthew (*Am N Y Acad Sci*, 24, pp 215 16), but he offered no valid evidence

HENRY BURY

The Gate House,
Bournemouth West, Feb 1

British Industries Fair.

THE British Industries Fair, 1930, which was held in two sections, one in London and the other in Birmingham, on Feb 17-28, has, from all accounts, been the most successful Fair of the series organised by the Department of Overseas Trade and held annually since 1915 In particular, it has had a greater success than ever before in fulfilling its primary object of attracting important overseas buyers and bringing them into touch with the British producer It is a commonplace of talk in high industrial circles that Great Britain is far behind many other countries—especially those with which it is brought into keenest competition—in the art of salesmanship The steady growth of this Fair is encouraging evidence that we are learning and mastering at least one of our lessons in this vital business art

This year the London section of the Fair was held at Olympia instead of, as formerly, at the White City, and the change has been a great gain to the appearance, compactness, and efficiency of the Fair as a business exhibition designed to do business Moreover, no visitor making a circuit of the exhibits could fail to be impressed with the variety and, in many cases—perhaps, in general—with the high quality of the goods that are being manufactured in Great Britain in these days, notwithstanding the impression created by the unemployment figures and by those journalistic jeremiads, justifiable and unjustifiable, as to the condition of British industry, that disturb the equanimity of many a British citizen's breakfast table Indeed, the psychological impression produced on the visitor by an observant tour of the exhibits is not the least of the valuable results achieved The Britisher, in particular, may well exclaim If we are doing so much so well, may we not do more even better ?

The process of what is generally termed rationalisation in industry aims comprehensively at doing better this more As was pointed out in a recent article in NATURE, rationalisation implies essentially the application of scientific knowledge, methods, and research to all the factors of industry—materials and processes, the human elements, salesmanship, and the financial and administrative organisation Just as Goethe's dying cry was for "more light", so the living cry of British industry to-day must be for "more science" If that be so, the condition of those British industries which are predominantly and essentially scientific is of vital importance to Great Britain The great chemical industry, in regard to both heavy and fine chemicals, obviously enters so largely into nearly all other industries that there is no need to stress its importance But neither the application of scientific research to the problems of industry, nor continuous scientific control, regulation, and testing of the processes and products, is possible without the aid of scientific instruments of all sorts The impression made, therefore, at the British Industries Fair by these two broad categories of scientific industries—chemicals and scientific instruments—is one that must be taken into account in any assessment of the Fair as an indicator of the scope and character of British industry In any case, the exhibits of these products are those in which readers of NATURE are most likely to be generally interested

The first point to be noticed is that in these two industries—or groups of industries—great advantage was gained by having the exhibits organised wholly or largely under the auspices of the organisations representative of the respective industries The arrangements for the Chemical Section were made under the auspices of the Association of British Chemical Manufacturers, and the exhibits in this section constituted one of the most imposing and convincing testimonies that the Fair provided of the wide range and excellence of British products It is impossible in the space at our disposal to attempt a review of the chemical exhibits, but a few of special scientific interest may be mentioned The British Drug Houses, Ltd, showed specimens of the following new products among their medical specialities acetylcholine, iodised tincture of guaiacol, and the vitamin products, radiostol, radiostoleum, and radio malt Hopkin and Williams (Travancore), Ltd, showed a collection of rare-earth minerals, including monazite sand from Travancore, which is claimed to be the richest in thorium oxide of any sand produced in quantity in the whole world The exhibits of Thorium, Ltd, included mesothorium (a by product of the thorium industry and found in monazite sand), which is largely employed medicinally and in the manufacture of self luminous compounds in place of radium The very impressive stand of the Imperial Chemical Industries, Ltd, included a small cinema where films were shown exhibiting the manufacture of explosives and of other products of constituent firms of that organisation

The exhibits of scientific and optical instruments gained enormously this year by being organised, for the most part, under the auspices of the British Optical Instrument Manufacturers' Association The large stand on which the exhibits of the constituent members of this Association were shown was one of the most striking features of the exhibition Other stalls of scientific and optical firms not within the membership of the Association were grouped near to this exhibit The total impression produced by the exhibits of scientific and optical instruments, as well as of optical glass, was most encouraging to the visitor desirous of being reassured that the products of these British industries need not fear comparison with the most renowned foreign products of like categories The developments in the highest types of binoculars were, in particular, striking On the stand of Messrs Ross, Ltd, for example, there was a stereo prism binocular of extra wide field and magnification of 7 diameters, specially designed for use at dusk and for observation at night The light transmitting

power of this instrument is remarkable, the central illumination being, it is claimed, fully 20 per cent and the illumination at margins of field 137 per cent greater than that obtained with other binoculars of the same power and aperture Messrs Barr and Stroud, Ltd, have introduced a novel element in the design of their binoculars by the use of bakelite for the usual enamelled metal parts, which has enabled the weight to be reduced We have not space to mention more of the many other excellent and novel exhibits of this section, but one general observation should be emphasised

We have already said that the scientific and optical instrument exhibits gained greatly this year by being, in great part, organised on a fairly representative single stand But while this method of exhibition has its great and obvious advantages, it can yield its greatest benefits only if it receives the whole hearted co-operation of all, or nearly all, the firms in these important industries We talk of mass action in chemical reactions, there is such a thing as mass mental effect, both as to quantity and quality, in exhibitions, and it is of great importance to realise that a visitor to the British Industries Fair, and more particularly, perhaps, a foreign visitor, cannot help getting from the exhibits of scientific and optical instruments a general net impression of what these British industries as a whole are like For this reason it is important that, at least, all the leading firms in the industry should realise the opportunities the Fair offers for creating an impression of the scope and quality of British scientific and optical instruments, quite apart from any direct benefits that may accrue to individual firms

The Function of Phosphate in Alcoholic Fermentation [1]

By Prof ARTHUR HARDEN, F R S

NATURE AND FUNCTION OF THE PHOSPHORIC ESTERS PRODUCED

If we next consider the exact nature of these phosphoric esters and the relation of their formation and hydrolysis to the decomposition of the sugar molecule, we are met with a singularly complex condition of affairs, which cannot yet be interpreted satisfactorily The main facts seem to be as follows

When fermentation of sugar by yeast preparations is carried out under suitable conditions in the presence of added inorganic phosphate, a rapid production of carbon dioxide and alcohol occurs and a phosphoric ester of a sugar accumulates, the amount of phosphate found in this form being approximately proportional in the ratio (CO_2/PO_4) to the increased production of carbon dioxide and alcohol caused by the addition of the phosphate (Kluyver and Struyk, it is true, have found lower ratios than this, but there is no doubt that high ratios, 0 8-1, are often observed)

The phosphoric ester produced, however, may consist mainly of the hexosediphosphate originally described by Young and myself or of the hexosemonophosphate described by Robison and myself and afterwards studied by Robison, or it may be a mixture of these in any proportions In the case of fermentation by dried yeast (and possibly of other preparations), a further complication is afforded by the fact that a disaccharide phosphoric ester (trehalosemonophosphate) may also be present

This conclusion is founded in the first place on a large amount of experience which has been gained at the Lister Institute in preparing hexose-mono and di-phosphate These preparations are as a rule carried out by making repeated additions of phosphate and sugar to a fermenting mixture of yeast juice or dried yeast and fructose (or glucose) With dried yeast a large proportion of the diphosphate is usually obtained, and the relatively small amount of monophosphate produced contains a considerable proportion of trehalosemonophosphate With yeast juice the results are very variable and no trehalosemonophosphate has so far been detected among the products More precise experiments have been made by Lord Henley and myself in which the gas evolved after a single addition of phosphate was carefully measured and the proportions in which mono- and di phosphates were produced were determined as accurately as possible Unfortunately, the available methods are not very good as they rest on the solubilities of the different compounds in 10 per cent alcohol, and these are to some extent mutually affected in the presence of both compounds Further, yeast, like Africa, is always yielding something new, and the recently discovered fact that pyrophosphates exist in yeast and by their formation from, or hydrolysis to, orthophosphates may cause disappearance or appearance of 'inorganic phosphate', adds another source of inaccuracy to the many previously known

Allowance has, of course, to be made for the phosphorus compounds existing in the mixture at the moment of addition of inorganic phosphate and for the normal evolution of carbon dioxide which occurs throughout the experimental period in addition to the enhanced evolution due to the esterification

In spite of these minor uncertainties, the somewhat surprising fact emerges, that whatever the nature of the phosphoric ester which accumulates, the carbon dioxide produced is approximately equivalent in the ratio CO_2 PO_4 to the amount of phosphate which undergoes esterification The full results are given in two papers published recently by Lord Henley and myself in the *Biochemical Journal*, and need not be quoted here in detail These experiments indicate the wide variation which may occur in the nature of the hexosephosphate produced, whilst the ratio of CO_2 PO_4-esterified remains

[1] Continued from p 279

constant and approximately equal to unity Two extreme cases may be quoted, in one of which 13 5 per cent of the phosphate (PO_4) esterified was present as hexosediphosphate and 86 5 per cent as monophosphate and, in the other, 97 per cent as diphosphate and only 3 per cent as monophosphate, the CO_2/PO_4-esterified ratios were 0 98 and 0 86 respectively

I do not propose to discuss in any great detail the various theories which have been proposed to explain these complicated relationships It would be natural to assume that the introduction of the phosphoric acid group into the sugar molecule forming a hexosemonophosphate might render this more accessible to decomposition into the compound (or compounds) containing three carbon atoms which are now accepted as an intermediate stage in the production of carbon dioxide and alcohol The phosphate radical from one of these groups might then serve to convert another molecule of the monophosphate into the stable diphosphate (Meyerhof)

$$2C_6H_{11}O_5PO_4H_2 = C_6H_{10}O_4(PO_4H_2)_2 + 2CO_2 + 2C_2H_6O,$$

or two of the three-carbon groups containing each one phosphate group might unite with each other forming the stable diphosphate (Kluyver and Struyk)

$$\begin{aligned}2C_6H_{11}O_5(PO_4H_2) &= 2C_3H_6O_3 + 2C_3H_5O_2(PO_4H_2)\\ &= 2CO_2 + 2C_2H_6O + C_6H_{10}O_4(PO_4H_2)_2\end{aligned}$$

Any monophosphate escaping these reactions would be found as a constituent of the mixed hexose phosphates resulting from the fermentation

To add further to the difficulty of unravelling this complex tangle, it must be remembered that, whether glucose or fructose be fermented, the hexosediphosphate produced is probably a derivative of fructose, or at least yields fructose on hydrolysis, whilst the monophosphate is with equal probability a mixture of about 80 per cent of a glucosemonophosphate and 20 per cent of a fructose monophosphate It is obvious from this that whatever changes occur are not limited to the simple introduction or removal of a phosphoric acid group, fundamental changes occur in the constitution of the molecule of the sugar itself

Attractive as is the theory of the intermediate character of any one of the hexosephosphates, it seems to me impossible at the moment to bring it into agreement with some of the facts which have just been related The production of 70 80 per cent of the monophosphate, with an unaltered degree of formation of alcohol and carbon dioxide, renders it impossible that this ester should be "obviously nothing but a part of the intermediate product which has escaped the coupled decomposition—esterification reaction" (Meyerhof and Lohmann, *Biochem Z*, **185**, 155, 1927)

It appears to me that the fundamental idea expressed in the original equation of Harden and Young is nearer the truth than any alternative that has as yet been suggested A coupled reaction of some kind occurs, as the result of which the introduction of two phosphate groups into certain sugar molecules—either into the same molecule or one each into two different ones—induces the decomposition of another molecule The introduction of these phosphate groups in the presence of muscle extract, and presumably in both muscle itself and yeast, is actually accompanied by a small evolution of heat (Meyerhof and Suranyi, *Biochem Z*, **191**, 106, 1927), and it is possible that this may have some significance for the occurrence of the coupled reaction What are the conditions for the preferential formation of the mono or di ester we do not yet certainly know, although the work of Kluyver and Struyk suggests that dilution of the enzyme may be one factor in this

The mechanism of the fermentation of the mono ester has not yet been worked out in sufficient detail to afford valid evidence either for or against the theory, but Dr Robison and I have made experiments (about to be published) which show that the monophosphate itself reacts with a further quantity of phosphate and that this reaction is accompanied by an enhanced production of carbon dioxide and alcohol

The lack of exact chemical equivalence among the products (ester on one hand, carbon dioxide and alcohol on the other) is probably more easily explicable on this view than on any other

Sugar Metabolism in Vegetable and Animal Organisms

After the establishment of the important part played by phosphates and phosphoric esters in alcoholic fermentation, it was soon found by various workers that these compounds provided the clue to many other biological phenomena The co zymase of alcoholic fermentation was found by Meyerhof to exert an equally important part in the respiration of yeast, and the important observation was made also by Meyerhof, that it occurred in muscle and was an essential factor in the carbohydrate metabolism of muscle, in which the intervention of a hexosephosphate had been proved by Embden This phenomenon was shown to take place on lines quite similar to those of the respiration and fermentation of yeast, and in 1924, before the riddle of lactic acid formation had been completely solved, Meyerhof wrote ("Chemical Dynamics of Life Phenomena") "It may indeed be considered a success of general physiology and its mode of experimenting, that the chemical dynamics of a highly differentiated organ like the muscle could be partly revealed by the study of alcoholic fermentation of yeast"

A still greater success was to follow An astonishing degree of similarity was shown to exist between almost every detail of the production of lactic acid by the muscle enzymes and of alcohol by the yeast enzymes, which extended to the identity of the phosphoric esters concerned, the accumulation of ester under similar conditions and even to the effect of arsenate on the process After the publication of Meyerhof's preliminary papers in which these observations were recorded, I wrote

Cellulose in the Light of the X-Rays[1]

By Sir William Bragg, K B E , F R S

ONE of the most fascinating features that emerge during the closer study of natural constructions is surely the extended use of certain atoms, certain molecules, and certain ways of combining molecules, while other atoms, molcules, and combinations are but seldom employed Thus, for example, half the world of which we have knowledge is made of oxygen silicon is used to the extent of 27 per cent, aluminum 8 per cent, iron and a few others make up most of the remainder, and some eighty or more of the 92 kinds of atoms cannot muster 2 per cent between them The seas that cover the larger part of the earth's surface give to the water molecule H_2O easy precedence over all others In the rocks, the oxygen atoms govern the structure the recent work on the silicates by W L Bragg and his collaborators shows us that we may regard the great bulk of the earth's crust as a piling together of bulky oxygen atoms cemented by atoms of other kinds such as silicon, aluminium, iron, or magnesium Sometimes the piling is of the simplest character, and seems to depend for the most part on considerations of space to be occupied Sometimes, as in quartz, more complicated structures are framed in order to satisfy the directional qualities of the mutual attractions of silicon and oxygen

If we take special note of the elements of living structure, the extraordinary predominance of the carbon atom at once attracts attention Though the mass of the carbon in the world is only about a fortieth of one per cent of the whole, its importance to life is extreme Two forms of molecular constitution are outstanding the long-chain of carbon atoms which is the basis of so many substances, fats, oils, paraffins, and so on, and the benzene ring in which six carbon atoms are tied together strongly into hexagonal form A very large proportion of organic chemistry deals with the properties of these two forms of molecules and of their derivatives , they are of the greatest importance in regard both to biochemistry and to the chemistry of industry

[1] Discourse delivered at the Royal Institution on Friday, Jan 24

Cellulose and Fibres

Cellulose is the fundamental molecular combination occurring in vegetable growth One has but to remember that forests and shrubs and grasses and plants of all kinds are mainly composed of cellulose to realise the strangeness of such a particular selection What is there in the cellulose molecule or combination of molecules that its responsibility should be so great ? It is preeminently the molecule of growth in the vegetable world It is found in the animal world also It must be a molecule by the aid of which purpose and direction can be worked out A mass of cellulose as it occurs in a plant cannot be of equal properties in all directions, for growth has to take place along definite lines With one or two stray exceptions, such as asbestos, the bulk of inorganic substances do not display that curious feature which we describe in a word as 'fibre'

Cellulose is a fibrous material, and its molecule or its molecular combination must somehow give it this fundamental character The fibrous character of the stem and leaves of plants is their most obvious characteristic the marked quality of direction is at the basis of their manner of growth and their constructional possibilities These qualities, moreover, we use for our own purposes We spin the natural fibres of cotton and hemp, ramie, jute, and the like, forming threads and ropes which have the special quality of standing strain in one direction We weave cotton goods , and we use the comminuted cellulose to make paper In these cases the fibres are distributed in one plane in more than one direction and so form sheets that stand two dimensional strain Of late years the cellulose, specially treated in various ways, is drawn out into threads of artificial silk, or rayon This fibrous quality is therefore essential not only to Nature's employment of cellulose, but also to the use that we make of it We should like to know exactly what cellulose is, and what there is in the curious structure that justifies this extensive use

Chemistry of Cellulose

The main attack upon the question has been made by the chemists, who have found it a simple matter to analyse cellulose into its constituent atoms it may be described as a multiple of $C_6H_{10}O_5$ But of course this description is quite insufficient to explain its properties there are, in fact, several other substances of the same composition, such as starch, glycogen, dextrin The distinctive properties of cellulose must depend on

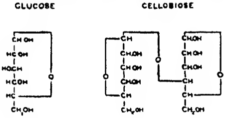

Fig 1

how these twenty one atoms are arranged with respect to one another We must therefore endeavour to discover the design It would be quite out of place to attempt a description here of the chemist's attack upon the problem of position We have already heard, at the Royal Institution, a general account of the atomic positions in the sugar molecule from Sir James Irvine, who has himself been a pioneer in this field Cellulose is closely allied to the sugars, indeed their basic features are the same A brief description of some of the chemical results will be quite sufficient for our purpose

It is certain that the six carbon atoms are connected in a chain But the chain is not to be thought of as drawn out in a straight line The chemist writes a formula of a straight line character, when he wishes merely to show which atom is attached to which, but his meaning goes no further Fig 1 shows the usual method of writing the formula for glucose, of which the $C_6H_{10}O_5$ group is the anhydrous form

Each carbon atom is attached to four other atoms the positions of the hydrogens and the OH groups, right or left of the carbons, have a meaning in that if any pair is inverted the character of the substance changes The most curious feature of the diagram is the connexion of the first and the fifth carbon atoms through an oxygen Possibly the diagram is wrong in that it should be the fourth that is joined to the first The latter view was favoured for many years, but later researches, especially by Haworth, make the 1 5 junction the more probable, and we will adopt it provisionally

Clearly, when we come to think of this set of atoms as a group in space, we must make arrangements for the oxygen at the side of the diagram to get into contact with the two atoms to which the formula attaches it Getting into contact means that the centre to centre distance between two atoms is a quantity which under similar conditions may be considered to be fairly constant It would be impossible to think of an oxygen touching the first and last of five carbons in a straight line The chain must be bent round until contact is possible, and at once we have the idea of a six atom ring, five carbons and one oxygen

There is no doubt that this ring is the basic element of all living plants and of numbers of those substances which can be derived or made from plant materials The fact stirs the imagination and the desire to investigate the remarkable structure by every means at our command A similar urge comes from the many industrial enterprises that use cellulose, from the cotton workers of every kind, from the huge concerns that make artificial silk, from the paper makers, from those concerned with celluloid, explosives, certain varnishes, and a host of other things

It has not been possible so far to go by chemical means much beyond the point already described

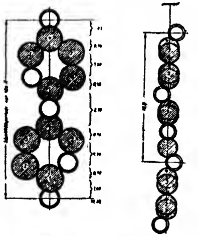

Fig 2—Model of cellobiose Shaded circles represent carbon atoms; oxygen atoms are drawn as double rings to show the limits between which their diameters probably lie This model, due to Mark, shows two glucose rings, stripped of atoms unessential for the purpose of showing the method of combination, and joined together by an oxygen to form the kernel of the cellobiose molecule Two views of the model are shown It should be compared with Fig 1

The indications become hazy, and the chemists are divided as to their meaning The most important step is the statement of the formula of the substance called cellobiose which has been derived from cellulose Cellulose, it will be remembered, is a multiple product of the element $C_6H_{10}O_5$, it is some compound made up of the rings just described,

generally known as glucose rings Cellobiose contains two rings, and the chemical evidence is in favour of combination in the manner indicated, according to chemical conventions, by the right hand formula of Fig 1 The first carbon of one glucose ring is joined to the fourth carbon of a second ring In the process, one oxygen and two hydrogens, the constituents of a water molecule, have disappeared from the combination It is further held that by tacking on a third ring with a similar oxygen linkage, cellobiose may be extended to form cellotriose, which consists of three rings, and that, finally, by the continued addition of rings, up to an indefinite number, we have the essential structure of cellulose The actual arrangement in space is probably as represented in Fig 2, but this diagram contains some information which only X rays could supply We had therefore better leave the construction at this point and consider the X ray evidence

Evidence of X ray Methods

Let us remember that the new method of X ray analysis derives its power from its capacity to detect any regularity of arrangement of atoms or molecules To such dispositions it is very sensitive it can record a perfect array of a few hundred molecules or so, or an imperfect array if the number is greater

We have seen that there must be in cellulose some directed quality, if it is to play so important a part in growth as it appears to do Of course, it may be said that direction is possibly attached as a property to some other constituent of the plant, the identity of which is yet unknown But, on one hand, cellulose is common to all plants, and their most prominent content, on the other, it turns out, as will appear, that it is easy to understand how cellulose can have the quality that we look for Now we cannot imagine how direction is to be obtained without regularity of arrangement There must be a pattern, involving the constant repetition of some form of grouping, which we might expect to be related to the line of growth We might then look at once for some such effect, when an X-ray is sent through a fibre of cotton or ramie or hemp, as we have become accustomed to find when X rays act on a photographic plate after traversing a crystal A crystal is merely a crowd of atoms in regular array

When the experiment is made, the effect is found at once Moreover, it is a kind that we recognise as indicative of fibrous nature Let us look at this point a little more closely.

When a pencil of homogeneous X rays passes through a crystal which is made to revolve about an axis, one set of crystal planes after another comes to its proper angle for reflection, and the reflected ray leaves the crystal in a direction inclined to the primary pencil at twice the reflecting angle We must remember that all the lattice points in the crystal, that is to say, points representing all the units of pattern, can be looked on in an infinite number of ways as lying on sets of parallel, equidistant planes The proper angle for reflection θ

Fig 3 —Asparagine X ray diagram obtained by W H George using the rotation method The X rays are monochromatic, and the crystal is rotated during the exposure The network at the back of this diagram is placed there for convenience of interpretation

is connected with the wave length (λ) of the rays and the spacing (d) of the planes by the law $n\lambda = 2d \sin\theta$, n being any integer

A photographic plate may be placed to receive the various reflected rays, and if both rotation axis and plate are perpendicular to the primary pencil, a symmetrical figure is formed on the plate An example is given in Fig 3 The crystal was in this case asparagine, which is a derivative of one of the constituents of wool The weight of the crystal was of the order of a milligram

From the positions of the spots and their intensities, the X-ray methods draw information respecting the crystal structure This is clearly a matter of calculation, based partly on geometry and partly on physical theories as to the reflection process We do not stop to consider the details The work of interpretation is by no means easy at all points but some results can be obtained at once and accurately, others are more difficult and less certain.

The clear separation of the spots on the asparagine photograph and their arrangement on a few well-marked lines show that the axis of rotation has coincided with an important direction in the crystal, that is to say, a line which passes through many lattice points to the unit of length, and is the intersection of a number of important sets of planes The lattice points lying on the axis are of necessity equally spaced along it, this must be so in a crystal The magnitude of this spacing is readily obtained from the photograph The spots obviously lie on a set of hyperbolæ If v_n denotes the distance of the vertex of the nth hyperbola from the horizontal line, which is called the equator, and if D is the distance from the crystal to the photographic plate, the spacing in question is equal to $(\lambda \operatorname{cosec} \theta)/n$ where $\tan \theta = v_n/D$ The proof of this rule is to be found in books on the subject Unless the spots are very hazy, this determination can be made with, at the very least, an accuracy of one or two per cent

Obviously, if a crystal were made to revolve about three different axes (not coplanar), we should in a similar way find the periodicities in three corresponding directions in space and so determine the form of the crystal lattice

X ray Diagram of Cellulose

Now if we take some cellulose fibre, such as ramie, and place it so that a fine pencil of homogeneous rays passes through it, afterwards falling on a photographic plate as in the experiment just described, we find that a spot design appears on the plate of a character exactly the same as that of the asparagine photograph It is clear, therefore, that the fibre is in some respects crystalline There is, however, one significant peculiarity in the manner of obtaining the ramie photograph It is not necessary to rotate the substance as in the case of the asparagine The explanation is that the ramie contains not one crystal but many crystals which have in common one important direction, it must be important because the photograph has clear lines Otherwise the crystals may have any disposition about this line as axis, so that the diagram is like that which a single crystal gives when it is made to rotate

Fig 4 —X ray photograph of ramie fibre

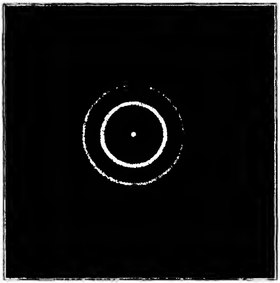

Fig 5 —Cystine This kind of diagram due to W T Astbury is typical of a substance consisting of a multitude of very small crystals not arranged with respect to each other

It will be observed that the ramie photograph (Fig 4) is not so clear as the other That is mainly due to the incompleteness of the array of the crystals with respect to each other

Suppose that the disarray were complete, as it would be if the fibrous material were so pounded or otherwise treated that the crystals pointed all ways There could then be no particular directions on the photograph, no vertical or horizontal lines of symmetry There could only be a set of rings, as if the fibre photograph were spun rapidly in its own plane about its centre An example of such a photograph is given in Fig 5, the material is cystine, one of the constituents of wool It is due to W T Astbury of the Textile Research Department at the University of Leeds

When the spots in the photograph are sharp, we conclude that the crystals are well oriented in respect to one direction, the fibre direction When there is no orientation at all, the result is as in

Fig 5 Every stage between is possible , with a small departure from orientation, the spots merely begin to spread along the circles on which they lie

Some of the blurring is due, however, to the smallness of the crystals The X ray action is of the nature of a diffraction, and it is well known that sharp images denote the combined action of many regularly arranged objects and vice versa It is even possible to estimate roughly the number of the diffracting centres in the crystal from the spreading of the spot This has been done by H Mark, whose work on the whole subject is of first importance

If now we measure the distances of the vertices of the hyperbolæ from the equator in this ramie photograph, we can, as already explained, find the length of the periodicity along the rotation axis It comes out to be 10 3 A (1 A = 10^{-8} cm)

Summing up, we now know that

(1) Cellulose contains crystals which may be invisible in the microscope but are clearly indicated by the X rays they are usually termed crystallites

(2) These crystallites are partly oriented, having one direction in common, more or less

(3) In each crystallite there is a periodicity in this special direction of 10 3 A This is often called the 'identity period'

It may not be safe to say that the whole of the cellulose is composed of crystallites, but there is a strong temptation to assume that this is so Cellulose is a multiple, as regards content, of the unit $C_6H_{10}O_5$, as we have seen reason to suppose that this unit forms a ring which is the basis of the structure The X rays do not suggest the presence of a second structure, having any real difference from the first and we suppose, therefore, that the ring structure pervades the mass When the X ray methods become more reliable in the matter of measuring the intensities of the reflection due to a given weight of the substance, in comparison with other substances of similar and known structure, we shall be able no doubt to answer this question conclusively

Comparison of the Chemical and X ray Analyses

We now return to the results of the chemical examination of cellulose and ask how our new results harmonise therewith As regards the first two deductions stated above, there can of course be no contradiction we have simply obtained some additional information on the matter of structure But the third deduction is of rather a different nature If chemistry has suggested a special arrangement of the atoms, it must show a reason for the periodicity that has been discovered Now the X rays have shown us that atoms of carbon and oxygen, when built into the regular structure of crystals, can be said to have dimensions They do not behave so simply as to warrant our thinking of them as hard spheres But when the state of combination of two atoms is known, the distance apart of their centres can be stated within limits so close as to give a determining value to estimates of structure

We know that two carbon atoms bound together in that strong fashion, which is sometimes described as due to the exercise of principle valencies, and is found in diamond, graphite, benzene, hydrocarbons, and the like, are at a distance of very nearly 1 5 A from one another, centre to centre We are not quite so sure of the value of the similar distance in the case of oxygen and carbon But from parallel cases in calcite and elsewhere we can safely assume that it is about 1 2 A In Fig 2, due to Mark, an attempt is made to apply these known distances to the determination of the dimensions of the cellobiose double ring There is naturally some uncertainty about it because the form of the ring is not yet known accurately Moreover, the way in which the oxygen bridge is fitted in, while by no means devised *ad hoc*, can only be assumed from analogy with somewhat similar cases in other crystals

The length of the double ring comes out at 10 3 A, agreeing with the X ray results Notwithstanding all its possibilites of error, such a coincidence is most striking It certainly supports excellently the idea that cellulose is essentially a long chain compound in which the glucose rings form the successive links, being attached to one another by oxygen bridges as shown in Fig 2 According to Haworth ("Sugars", p 84) the unit that is constantly repeated is formed of two rings or links, not of one, which means that the links differ from one another alternately A difference of this kind is shown in Mark's figure the oxygen bridges lie, it will be observed, alternately on one side and on the other of the principal plane of the molecule There is an imperfect repetition of the pattern at each link, and a perfect repetition at each second link It is known that such a condition should manifest itself in the X ray diagram by the weakness of the spots in the first, third, and odd numbered hyperbolæ as compared with the strength of the spots in the even numbered The effect may wear off in the hyperbolæ of high number The weakness of the first cellulose

hyperbola as compared with the second is very obvious

Thus the X-ray evidence is certainly, so far, in favour of the conception of cellulose as formed of chains of glucose rings Throughout the whole length of the chain the bonds are of the strong type such as are found in diamond The conception has been put forward before (Herzog, *Zeit ang Chem*, **34**, 385, 1921 Polanyi, *Naturwiss*, 288, 1921), though by no means accepted It is described, for example, in Haworth's "Sugars" The American botanist Sponsler, who has also used X-ray methods, has maintained it ("Colloid Symposium Monograph", 1926) In particular, H Mark has argued strongly in favour of it, and has supported his views by much experimental research Nevertheless, there are cellulose chemists to whom the idea does not appeal Trogus and Hess, for example, have argued against it quite recently

If we try to estimate the value of such evidence as this, and of much more that will presently be considered, we must recognise that it is not fully decisive On one hand, there are many factors which are not fully understood, on the other, the X ray analysis is clearly far from its full development and does not yet handle its problems with the assurance of long experience But even now the X ray evidence has a distinct value it may be expected to be worth much more in the future In this particular case, it is satisfactory to prove a periodicity which a very interesting and promising theory of cellulose would lead us to expect

The Unit of Pattern of Cellulose

The diagram has obviously more to tell us than the value of the one periodicity we have been considering The positions of the separate spots have information to give which goes far to determine the form and dimensions of the unit of pattern Suppose the unit to be represented by the rhomboidal cell in Fig 6 The implication of the 'cell' is that if we moved our point of view in the crystal from O to A or to B or to C, we should not be able to detect the change Suppose that OB is the periodicity we have found, which we distinguish by writing 10 3 alongside All the other dimensions of the cell have yet to be found

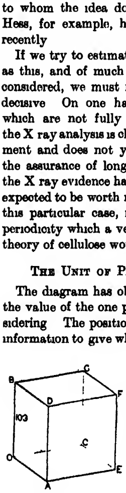

FIG 6

Every spot on the equator is made by a set of planes to which OB is parallel For example, the set of planes of which the planes $OBDA$ and $CGFE$ are consecutive members, contribute one spot to the equator row, and the position of the spot on the diagram gives us the perpendicular distance between the two faces mentioned So also for the pair $OBGC$ and $ADFE$ We may pick out two spots on the equator and decide, as we can with certain limitations which need not be discussed here, that we will make the planes to which these spots belong the faces of the unit cell But the diagram does not tell us directly what angle these faces make with each other If we had a single crystal instead of a multitude we should have no difficulty, because we should make a variety of diagrams by revolving the crystal about at least two other directions, such as OA and OC It is this lack of the single crystal that most contributes to the difficulty of our task

Nevertheless, we are not without means which will guide us indirectly if less certainly to a conclusion To begin with, the general appearance of the diagram considered in comparison with others of like origin suggests strongly that the crystal is nearly if not quite monoclinic In other words, the direction of periodicity OA and OC are nearly if not quite perpendicular to OB We may safely assume for the present that they are so For brevity's sake I do not argue this out in full If this is assumed, we have but one unknown left, namely, the angle between OA and OC To find it we have the perpendiculars from A on OC and from C on OA Also a definite assumption will carry with it the positions of all the other spots on the diagram, and though this is not so liberal in fresh information as it sounds, yet on the whole the determination of the angle is restricted to one or two very distinct possibilities

Much argument has been spent on the final choice It appears that all the details of the diagram are well satisfied if it is assumed that $OA = 8\ 35$ A, $OC = 7\ 9$ A, and the angle $COA = 84°$ nearly We have already determined OB to be 10 3 (Mark and Meyer, *Zeit Phys Chem*, **2**, 115, Andress, *Zeit Phys Chem*, **2**, 380)

An approximate knowledge of the specific gravity of cellulose is enough to show that this cell contains four of the $(C_6H_{10}O_5)$ groups

Our picture is now taking shape We picture these long chains as arranged parallel to OB (Fig 6) If the axis of one chain lies along OB, the axes of exactly similar chains lie along AD, EF, and CG Such an arrangement places the matter of two glucose rings within the six walls of the cell,

thus accounting for two out of the four rings Here calculations based on the relative intensities of various spots come to our aid, and in a manner which can be found in accounts of X rays methods, tell us that there is a chain in the middle of the cell, passing approximately through the centres of the faces *OAEC* and *BDFG* This accounts for the other two rings

The Crystallites

We must think, therefore, of the crystallite as composed of these long chains laid side by side like a bundle of sticks This prompts us to consider next the manner in which the sticks are held together

Now there is an obvious difference between the forces that bind together the links in each chain, and those that bind together the chains themselves The former are relatively very strong, all of them being of the nature of those that are found in diamond But the latter are due to the mutual action of carbon atoms the primary valencies of which are satisfied by attachments of hydrogens and of hydroxyl groups They are more of the nature of the forces that bind molecule to molecule in organic crystals like naphthalene When naphthalene melts or sublimes, its molecules are separated and these secondary valencies are snapped But the work to be done is very small in comparison with that which is required to snap the primary valencies in the molecule itself There are no hydroxyl groups in naphthalene, so that the second

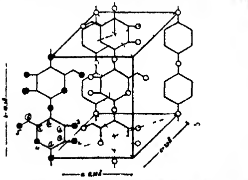

FIG 7 —Skeleton diagram showing the relative positions of the chains (From Mark and Meyer, *Zeit phys Chem*, 2, 122, 1929)

ary forces are not so large as those we may expect to find in our present case But still there must be a very great difference between the forces within the chain and those from chain to chain

We find internal evidence in the structure of our model which is entirely in sympathy with this view While the centre to centre distance of carbon atoms bound by primary valencies is nearly 1 5 A, the distance of closest approach of carbon atoms belonging to different molecules is about 3 5 A In graphite, for example, the layers are separated by a distance of 3 41 A In naphthalene, the corresponding distance is about 3 5 A, in the fatty acids it is the same If we consider the cellulose model, we see that some such distance must be assumed here also Otherwise, the chains would not come into contact with each other, they would not fill up the volume For example,

FIG 8 —X ray photographs of a paraffin, $C_{19}H_{40}$, at the ordinary temperature (*A*), and at the temperature of liquid air (*B*) (Dr A Müller) The lines in the centre are due to the various orders of reflection by the long spacing, which is actually the length of the carbon chain These are in the same positions in the two photographs But certain lines farther out are due to the sideways spacings of the chains, and these are considerably shifted by the change in temperature

the model shows the planes of the ring lying mainly in the *ab* and parallel planes, as in Fig 7, due to Mark and Meyer (*Zeit phys Chem*, 2, 122, 1929) The reflection from this set of planes is by far the strongest on the diagram, which is indeed a very important guide to the construction of the model The distance from plane to plane is 3 95 A, which fits in very well with hypothesis

Temperature Effects

A certain measure of confirmation comes from a different quarter The coefficient of expansion of diamond with temperature is exceedingly small In the case of graphite it is very small in the plane of the sheets, but many times greater at right angles thereto (Backhurst, *Proc Roy Soc*, 102, 340, 1922) In other words, the sheets do not stretch as the temperature rises, but draw apart from each other

It is to be remembered that a comparison of X-ray diagrams at different temperatures shows the expansion coefficients in every direction in a crystal This is possible even when the crystal is microscopically invisible, though the accuracy is not so great as when we have a single perfect crystal that can be handled

The observations on diamond and graphite suggest strongly that the strong carbon bonds in diamond and graphite stretch or contract very little with changes of temperature, while in the case of the weak bond in graphite there is a very

appreciable alteration in the centre to centre distance

The point is further illustrated by an effective experiment due to Dr Müller A comparison of the two photographs in Fig 8 shows that temperature affects the length of a carbon chain far less than the distance that separates the chains from one another

No doubt the changes in form which a crystal experiences when the temperature is varied are often complicated and are difficult to interpret But in these simple cases it seems clear that we are observing a difference in the reaction of primary and secondary valencies

We might certainly expect very little change in the dimensions along the cellulose chain when the temperature is lowered to that of liquid air This is exactly what Mark and Meyer have found (*Zeit phys Chem*, **2**, 127) But there is a considerable change in other directions

Mercerisation

The process known as mercerisation, so very interesting from the scientific point of view, and so important industrially, produces notable changes in the X ray diagram Yet so many of the original features remain that the new structure is obviously to be regarded as a modification of the old Most important is the fact that there is no change in the dimensions of the separate links of the chain Andress (*Zeit phys Chem* **4**, 190) has shown that the new diagram can be fully explained if the sideways relations of the chains with respect to each other are somewhat varied, in the manner depicted in Figs 9 and 10 The new arrangement is regarded as that of the stable form of the crystal, the older as the metastable

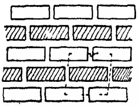

FIG 9 — General disposition of the cellulose chains, looking along the c axis

The permanence of the identity period along the chain, and therefore of the chain itself, survives not only a physical alteration such as mercerisation, but also various chemical changes For example, there are forms of trimethylcellulose, of acetyl-cellulose, and of nitrocellulose, which are crystalline, are of the same general form as cellulose itself, and have the same periodicity of 10 3 in the fibre direction In other directions there are great changes, clearly the introduction of new atomic groups between the chains must push them apart, though there may be no change in the chains lengthways When by chemical means the stranger atoms have been taken away again, the original X-ray diagram of cellulose is restored, except that in some cases, depending on the nature of the treatment, the diagram of the recovered material is that of mercerised cellulose

There are, however, other examples of cellulose derivatives which show a more radical change as the result of chemical action Another form of nitrocellulose shows, according to Mark, an identity period of 25 A, and 15 A has been found in an acetylcellulose and a cuproamine cellulose

So, in general, the chain seems to retain its nature even when subjected to wide changes of temperature and to many chemical processes All this is in entire accord with the conception of the chain of glucose rings tied together through its whole length by strong bonds resembling those of diamond a conception encouraged by the studies of the sugar chemists and now supported by the X ray evidence By sideways bonds the chains are tied together into bundles or micelles, and when the chains are long enough these sideways bonds, though individually far weaker than the others and more susceptible to physical and chemical action, will be strong enough to hold the bundle together as a definite element in the structure of the cellulose The process of the stretching and recovery from strain which fibres show in different degrees and ways, owe their many complications to the varied possibilities of gradual alterations in the alinement of the micelles, of their sliding past each other, of their partial recoveries, of their hysteresis, of their final partings when the strain is too great But these properties of fibre are fully treated in other places

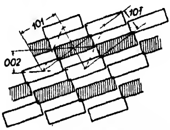

FIG 10 — General disposition of the chains in mercerised cellulose looking along the c axis

In fine, we have a striking and in some respects a very simple picture A particular form of atomic combination has been chosen by Nature to be the basis of all plant structure, and in its essential structure it already embodies the fibre principle The X ray analysis at least supports and gives some precision to views as to structure which have already been suggested There are great possibilities of improvement in the X-ray methods, and it may well be that before long their pronouncements will be much more definite

Printed in Great Britain by R & R Clark, Limited, Edinburgh

the following passage in concluding a short review of the work (NATURE, Dec 18, 1926) "The striking similarity established by Meyerhof between the changes of carbohydrates in muscle and in the yeast cell is seen to be much closer than has been believed The remarkable phenomena accompanying alcoholic fermentation are now duplicated in the case of lactic acid production, and it may reasonably be expected that most of the fermentative decompositions of the sugars will be found to be initiated in a similar manner"

Direct proof is still wanting in many cases, but some instances are known among bacteria (Virtanen), moulds (Euler and Kullberg), and higher plants (Ivanoff, Bodnar) It is not too much to say that the fundamental biological mode of attack on carbohydrates is that revealed by the study of alcoholic fermentation

OSSIFICATION

Another biochemical function of the hexose phosphates which is shared by other hydrolysable phosphoric esters is that of a potential source of phosphate ions I am happy to say that one of the most beautiful and important developments of this idea has been worked out quite independently at the Lister Institute by Dr Robison as a direct consequence of his work on the hexosemonophosphate of yeast juice "During my investigation of the hexosemonophosphoric acid isolated from the products of fermentation", he said (*Biochem J*, 17, 286, 1923), 'the hydrolysis of the ester by enzymes was studied In some experiments in which the readily soluble calcium and barium salts were used as substrates, the progress of the hydrolysis was shown by the formation of a precipitate of sparingly soluble calcium or barium phosphate $C_6H_{11}O_5PO_4Ca + H_2O \rightarrow C_6H_{12}O_6 + CaHPO_4$

The formation of this precipitate suggested to me the query whether some such reaction might conceivably be concerned in the deposition of calcium phosphate during the formation of bone in the animal body In the first place I sought for an enzyme capable of effecting hydrolysis in the bones of growing animals"

The search was successful, a 'bone phosphatase' was found in the ossifying cartilage of young animals and a series of interesting and important investigations has followed, as a result of which I have little doubt that their author is on the highway to the biochemical explanation of the process of ossification—a good instance of the far reaching and unexpected results flowing from observations made for quite a different purpose

Obituary

PROF J M DUNCAN SCOTT

DR JAMES MATTHEWS DUNCAN SCOTT, professor of physiology in the University of Saskatchewan, died at Saskatoon on Jan 28 last Prof Duncan Scott's career as a physiologist was a relatively short one After taking an arts degree at St Andrews, and qualifying in medicine with honours at Edinburgh, he joined the forces during the War and served in Egypt At the conclusion of the War he suffered ill health for some years, owing to a troublesome frontal sinus infection which necessitated surgical intervention

After practising for a time in South Africa, Duncan Scott felt called to undertake scientific work, which had always had a strong attraction for him, and in 1921 he proceeded to Cambridge, where he held a John Lucas Walker Studentship for research in pathology His work at Cambridge was largely concerned with the regeneration of the red blood cells in anæmia Becoming interested in physiology, and particularly in the teaching of it, he obtained in 1924 a teaching post at St Bartholomew's Medical College as junior demonstrator, and afterwards became lecturer in physiology There he continued some investigations which had been commenced at Cambridge in collaboration with Dr Ffrangcon Roberts, on the situation and connexions of vagal and vasomotor centres in the medulla This work he prosecuted with great assiduity and considerable skill, as a research scholar of the British Medical Association As an outcome of his teaching work he also became interested in the physical chemistry of colloids, and held highly original, though not generally acceptable, views on that subject

In 1926, Duncan Scott was invited to the University of Saskatchewan to occupy the newly created chair of physiology This was an opportunity for the display of those fine qualities of orderliness and strict classification which had always characterised Duncan Scott Before leaving England and proceeding to found and equip a physiological laboratory under conditions of relative isolation, he prepared a list, accurately classified down to the smallest detail, of every article which would be required in such a laboratory He regarded his work there in a pioneering spirit, and as a field of high endeavour, he was, on the whole, well gratified with the results which came out of it so far as the organisation of the department was concerned The duties of organisation and teaching naturally distracted him temporarily from his research work, though he never entirely lost touch with this, and when at the annual Physiological Congress at Boston in 1929, at which he gave two demonstrations, he expressed the opinion that the first labours of organisation had now been definitely completed, and would, he hoped, leave him free to continue his research work

The passing of so courteous a colleague and of so keen a teacher and investigator will leave a gap among the physiologists of two continents Dr Duncan Scott leaves behind him a widow and three sons, to whom all his friends will extend their warmest sympathy

MR F W DOOTSON

MR FREDERICK WILLIAM DOOTSON, who died in Cambridge on Dec 12, 1929, after a very short illness, was born in Manchester on Aug 10, 1863

His long connexion with the University Chemical Laboratory at Cambridge dates from 1891, when he entered the University as an undergraduate at Fitzwilliam Hall After graduating in the Natural Sciences Tripos, he attached himself to Trinity Hall, and for many years was a successful private tutor He was also engaged in the teaching work of the Chemical Department, first as demonstrator and in later years as a University lecturer

In conjunction with the late W J Sell, Dootson published a paper on citrazinic acid, which was followed by a systematic series of investigations on the chlorine derivatives of pyridine He also published papers on derivatives of acetone di carboxylic esters, in one of which he demonstrated a very simple method for transforming an aliphatic into a benzenoid compound His last paper, published jointly with Dr S Chapman, was entitled " A Note on Thermal Diffusion "

In later years, the gradual increase in his administrative duties drew Dootson away from research During the period of the War, however, he was occupied with experimental preparative work on various substances of national importance His success as a teacher continued to the end, indeed many generations of Cambridge students will remember with gratitude his kindly and unsparing help, and his friends among the teaching staff will mourn the loss of a congenial and gifted colleague A J Berry

Dr Donald H A Hutchinson

Dr Donald H A Hutchinson, a master of the art of photomicrography, died of cancer on Feb 1, at the age of fifty-six years An ardent naturalist all his life, he concerned himself latterly with the photography of living microscopic animals by means of both still and moving pictures Many will remember the remarkable films of protozoan life which he exhibited at the Zoological Society of London in 1924 and at the British Association meeting at Oxford in 1926, but only his intimate friends will know of the amount of his work and of the patience and ingenuity with which it was achieved It was work carried out in the spare moments of a busy general practice He never sought publicity, but hoped eventually to produce an atlas of photographs of as many kinds of protozoa as possible He was always trying to get better and still better results

A few of Dr Hutchinson's photographs have recently been published in "The Science of Life", but there remain a large number of magnificent studies which have been seen by only a few The writer of this brief notice, who, during a few years at Lowestoft, spent many wonderful evenings in Dr Hutchinson's laboratory, intends to publish a volume of his photographs and some of the more interesting sections of his films, he believes that they will be of great value to students of animal life, and in addition a source of inspiration to workers in the field of photomicrography

A C H

We regret to announce the following deaths

Dr F Arnall, head of the Department of Pure and Applied Chemistry at the Cardiff Technical College, whose interest was mainly in organic chemistry, on Feb 7, aged thirty four years

Sir William Atkinson, I S O, formerly Divisional Inspector of Mines, Home Office, a past president and honorary member of the North Staffordshire Institute of Mining Engineers, on Feb 15, aged seventy nine years

Dr G G Chisholm, formerly reader in geography in the University of Edinburgh and secretary of the Royal Scottish Geographical Society from 1910 until 1925, on Feb 9, aged seventy nine years

Prof Felix M Exner, director of the Zentralanstalt fur Meteorologie und Geodynamik and professor of terrestrial physics in the University of Vienna, who was an honorary member of the Royal Meteorological Society, on Feb 7, aged fifty three years

Mr A A Campbell Swinton, F R S, known for his pioneer work on X rays and radio communication, on Feb 19, aged sixty six years

News and Views.

The problem of the structure of cellulose is one which has not only a fascination for the organic chemist but is also of the greatest importance in many industrial processes The method of X ray crystal analysis has been applied to supplement the older chemical methods, and the results of this work were set out by Sir William Bragg in a recent discourse at the Royal Institution which we are glad to be able to print as a supplement to this issue of Nature X rays have gone far to confirm modern views of the structure of cellulose and have succeeded in shedding new light on some aspects of the problem It has been shown, for example, that cellulose contains large numbers of small crystals which tend so to arrange themselves that they have one direction in common The outward sign of this selective orientation is the fibrous nature of the material In the direction of length of the fibre it is found that the atomic pattern repeats itself every 10 3 A The other dimensions of the crystal cell are less certain, but the evidence is consistent with the values of 7 9 A and 8 35 A at 84° to each other and perpendicular to the fibre axis Such a cell contains the substance of four $C_6H_{10}O_5$ groups Along the fibre direction there are chains of glucose rings (five carbons and one oxygen) linked together by oxygen atoms, the pattern repeating itself identically after every two rings, the length of which is 10 3 A One such chain starts from each corner and one from the centre of the base of the crystal cell

The structure of cellulose suggested by the X-ray examination throws light on its physical and chemical behaviour The atoms forming the chains of glucose rings along the fibres are very tightly linked together, while the chains are joined sideways by much weaker bonds due to the hydroxyl groups attached to the ring atoms. The cellulose micelle resembles a bundle of sticks, each stick strong in itself but loosely at-

tached to its neighbours The atomic arrangements and dimensions of the cell can be altered by physical and chemical means, but there is a strong tendency for the chains which lie along the axis of the fibre to remain unchanged The length of 10 3 A in this direction is affected by temperature much less than are the other dimensions Such a process as mercerisation leaves the periodicity of 10 3 unaltered, and the change accompanying this process can be explained as due to a slewing round of the chains about the fibre axis Many chemical derivatives such as nitro cellulose and acetyl cellulose show also this characteristic 10 3 A dimension, and the additional atoms introduced by the chemical actions result in an increase in the distance between adjacent chains It is interesting to note that when such atoms are removed, the structure reverts sometimes to that of the original cellulose and sometimes to that characteristic of the mercerised material

THE Council of the Royal Society, at its meeting on Feb 20, recommended for election into the Society the following fifteen candidates Herbert Stanley Allen, professor of natural philosophy, University of St Andrews, Edward Battersby Bailey, professor of geology in the University of Glasgow, Frederick T Brooks, University lecturer in botany, Cambridge, Paul Adrien Maurice Dirac, University lecturer in mathematics, Cambridge, Harold Ward Dudley, chemist, National Institute for Medical Research, Hampstead, Charles Alfred Edwards, principal and professor of metallurgy, University College, Swansea, Harry Eltringham, entomologist, Hope Collections, University of Oxford, Charles Edward Inglis, professor of mechanism and applied mechanics, University of Cambridge, Harold Spencer Jones, H M Astronomer at the Cape of Good Hope, Eric Keightley Rideal, lecturer in physical chemistry, University of Cambridge, Robert Robison, assistant chemist, Department of Biochemistry, Lister Institute, John Stephenson, formerly lecturer in zoology, University of Edinburgh, George Paget Thomson, professor of natural philosophy, University of Aberdeen, Charles Todd, Department of Experimental Pathology, National Institute for Medical Research, William Whiteman Carlton Topley, professor of bacteriology and immunology, London School of Hygiene and Tropical Medicine
